Q. And during the time of these analyses, to which you have testified, were you a Professor of Chemistry at Washington University?

A. Yes, sir.

Q. Had you or were you continuously in St. Louis from September at the opening of Washington University, until the time these chemical analyses commenced?

A. Yes, sir.

Q. Had you traveled up the Missouri River any to examine the character of the soil, and the locality from which the waters came, the Missouri waters?

A. I have been to the waterworks and I have been to some points on the Missouri River.

Q. Well, before you commenced these analyses or afterwards?

1759 A. Afterwards.

Q. Before you commenced these analyses had you traveled up the Mississippi?

A. No, sir.

Q. Or up the Illinois?

A. No, sir.

Q. Have you since traveled up the Mississippi with a view of examining the soil and the water and the sources of the water?

A. No, sir.

Q. Have you since traveled up the Illinois with such a view?

A. No, sir.

Q. Have you ever traveled up the Illinois River with a view of determining the sources of its water supply?

A. No, sir.

Q. Were you ever at Joliet?

A. No, sir.

Q. Or at Lockport?

A. No, sir.

Q. So that with the physical situation of the waters and the origin and derivation of the waters of which you have been testifying, you have no personal knowledge?

1760 A. I have not.

Q. Isn't that knowledge regarded as important in making up a judgment as to the water?

A. Only in so far as the water is of different origin from that which we have examined in this case. A spring with water or a well water, it is especially necessary to know the surroundings, the country, the soil and the character of the buildings, and so on, with that kind of water but the topography of the country in general through which the Illinois river runs has been described so frequently in reports by various scientific bodies and I have read those descriptions so that I have been able to form a very clear opinion on that point.

Q. That is from the reading of reports in regard to the character of the country through which the Illinois river runs?

A. Yes, sir.

Q. Does that report also show the character of the country through which the numerous feeders of the Illinois flow?

A. Yes, sir.

Q. What report is that?

A. I have read the reports of the Illinois State Board of 1761 Health, and I have read the reports that were issued by the University of Illinois on the chemical survey of the waters in the State of Illinois, and especially the Illinois river and its tributaries.

Q. But you had no personal observation of it whatever?

A. I have not.

Q. Now, for instance, do you know the character of the waters of Macoupin creek?

A. I do not.

Q. Or of the Sangamon River?

A. Only in as far as I have read about it in these reports.

Q. Or of the Mackinaw?

A. No personal knowledge.

Q. Nor of the Des Plaines?

A. No, sir.

Q. Nor any other one of the rivers or creeks that empty into the Illinois River?

A. No, sir, I have not.

Q. Your laboratory in which you carried on these analyses is where?

A. 17th and Washington avenue, St. Louis.

Q. During the entire time?

A. Yes, sir.

1762 Q. Is that a part of Washington University, that place?

A. Yes, sir.

Q. Now, what kind of premises was it in which you conducted these analyses?

A. A two-story brick building with all the appliances of a chemical laboratory. It was especially built for chemical work, analytical work.

Q. Well, did you carry this on in one room or a number of rooms?

A. The ammonia determination and the nitrite determinations were made in a room that was expressly reserved for work of that kind. The chlorine determinations and the total solids and the nitrates were carried on in an adjoining room and these rooms were given up entirely to this work. No other work was carried on there at that time. The analytical part of the work is done entirely on the ground floor of this two-story laboratory that I have mentioned.

Q. Could you give me a brief description of the interior of that laboratory on the first floor as to the walls and furnishings and colors?

A. The room in which the ammonia distillations were carried on was well lighted and supplied with working tables and

sinks and was especially constructed with apparatus for making
fourteen distillations of water simultaneously. There was
1763 a large condenser that had 14 condensing worms in it
made of black tin pipe and to each of these condensers
there was a dish, by means of a cork and bottle of Jena glass of a capacity of one meter into which samples of 500 cubic centimeters of each water was poured and this apparatus was heated with a Bunsen burner. In each case the glass was heated with a Bunsen burner and on the other side of the condenser there were a series of Nessler tubes of 50 cubic centimeters capacity of which the distillate from each flask was collected. There was also in this room water baths.

Q. What do you mean by water baths?

A. A water bath is a copper vessel for holding water that is heated by steam and evaporating dishes are placed on concentric rings on the back of these copper boxes, so that the dishes are heated by the steam coming up through the copper box, and the measured samples of water were filtered in the platinum dishes placed upon this water bath. Then in the adjoining room, a small room adjoining, we reserved for the determination of nitrites. The samples of water here were filtered through Swedish filters, Swedish filter paper and 100 cubic centimeters of each specimen that was analyzed was treated with
the Alpha Naphthalyne and with Sulphanilic acid and
1764 allowed to stand for 30 minutes for the development of
the color that is produced if nitrites are present in the
water.

Q. Was the water in your evaporating dishes exposed to the steam?

A. No, sir; the steam was underneath the dishes and the dishes were held in these rings and they were exposed to the air above.

Q. But the steam did not pass over them and come in contact with the evaporating water?

A. Except so far as it escaped from the rings. A little steam escaped from the water bath, but did not come directly in contact with the water in the dishes.

Q. Now, in these operations or distillations, by whom were you assisted?

A. I was assisted by Dr. Gellert Alleman, who at that time was an instructor in chemistry at Washington University, also by Dr. William H. Warren, who is a Professor of chemistry in the Medical Department at Washington University and by Mr. E. B. Fulks and by Mr. Sherman Leavitt during a portion of the time, and by Mr. Alfred Kammerer and by Mr. Robert Schmidt.

1765 Q. Did those gentlemen have especial parts of these analyses confided to them?

A. Yes, sir.

Q. For instance, what did Dr. Alleman do?

A. Dr. Alleman determined the chlorines in the samples of water and assisted with the nitrates.

Q. What did Warren do?

A. Warren gave his attention exclusively, together with one of the assistants, to the determination of free and albuminoid ammonias and the oxygen consumed.

Q. What did Fulks do?

A. Fulks did nothing but total solids and loss on ignition of the total solids.

Q. What did Leavitt do?

A. Leavitt did nitrites and assisted with the nitrates.

Q. What did Kammerer do?

A. Kammerer only worked a portion of the time and relieved Fulks at times and at other times relieved Alleman. Alleman was absent during two months in the summer time, when his work was taken by Fulks.

Q. What did Schmidt do?

1766 A. Schmidt prepared solutions and in general assisted in the work especially of determining total solids and assisted in the laboratory in general.

Q. Now, how much of the actual work of analyses did you perform?

A. Well, I was with these men every day and I kept the records carefully and I kept the solutions from day to day to see that their solutions were accurate, and it was, of course, an impossibility for me to make complete analyses myself. I had to simply see that these men did their work carefully and to check them from day to day by making separate analyses and by testing their solutions and in general having an oversight to see that the work was done faithfully.

Q. You mean by solutions the various reagents that were used in making certain results?

A. Yes, sir.

Q. And the standard solution by which comparison was made?

A. Yes, the scales of color for the ammonias and nitrites and nitrates.

Q. Now, as to the actual work as distinguished from the actual supervision, you did little?

1767 A. Well, in the early part I made altogether I should say, several dozen analyses independently.

Q. Complete?

A. Yes, complete.

Q. Did you make many after that time with reference to any particular pollution?

A. Yes, during one week Dr. Warren was taken ill, a week in the early part of July, 1900, and I did all of the free ammonias and albuminoid ammonias and the oxygen consumed processes, myself for about 10 days with the assistance of one of the younger men. I actually made distillations of 14 samples a day of free ammonias and albuminoid ammonias and I Nesslerized those distillates.

Q. Every day, from those 14 flasks?

A. Yes, sir.

Q. That is when you used 14 and 12 when you used 12?

A. Yes, sir.

Q. And you applied Nessler's solution to those for the determination of ammonias?

A. Yes, sir.

Q. Otherwise your conclusions are drawn from reports made by these various men as to their various determinations on the various things with reference to which they analyzed?

1768 A. Yes, but they never reported to me final results of analyses. They reported to me for instance, that the readings in the ammonias were certain numbers for each Nessler tube and I added up these figures myself and made the calculation for the parts per million.

Q. You did the mathematical work in that?

A. I did all the mathematical work in every analysis.

Q. Assuming that a flask of water came to your laboratory on a certain time, how long until the analysis of that particular flask was commenced?

A. We began immediately for the determination of nitrites and the free ammonias were done immediately, that same day, we finished up the nitrites and the free ammonias the same day.

Q. When would the other determinations be made as to that particular flask?

A. The other determinations were made the next morning. Our samples reached us about half past three to four o'clock in the afternoon of each day. For example, a sample that was taken at the Chain of Rocks or at Alton or at Grafton was sent down by express. The samples were taken in the forenoon and reached us about half past three to four o'clock and we immediately determined the nitrites and the free ammonias that same day, but the albuminoid ammonias and the
1769 chlorines and the nitrates and the total solids were made next morning.

Q. Now did those samples uniformly reach you packed or cased in ice?

A. Only in the warm weather.

Q. Only in warm weather?

A. Yes.

Q. During what months?

A. During the months of June, July and August, as I remember, until the latter part of September. I am simply giving this as far as I remember.

Q. Now, with reference to the water arriving at your place in June, July, August and September. When the water arrived the temperature was lower than when taken out of the river at the various places?

A. I made no determinations of the temperature of the water.

Q. Did you determine the temperature of the water at the time you commenced your first operations or analysis?

A. You mean the water that was delivered to me?

Q. Yes.

A. No, sir.

1770 Q. At no time?

A. At no time.

Q. During no part of the investigation?

A. No sir.

Q. Was the temperature of the water in your opinion lower in June, July, August and September when it arrived at your laboratory than it was when it was taken from its source?

A. I can hardly express any opinion on that. Perhaps sometimes it was a little lower. It was not at the freezing point, of course. It may have been lower it probably was in some instances.

Q. Now, for instance do you know on any particular day when the water was taken at the Chain of Rocks, the temperature of the river at the point?

A. No sir.

Q. And as to a sample taken upon a particular day the temperature of that sample when it arrived at your laboratory?

A. I never took any determinations of the temperature, but it was probably lower. It was probably lower because 1771 these bottles were put into refrigerators and were kept cold.

Q. Now of course low temperature does not produce as much chemical change in the water as higher temperature, not up to the boiling point, in a given length of time?

A. No, sir.

Q. Does it produce such change as to any particular element?

A. I don't understand the question.

Q. Well a bottle of water is taken out of the Mississippi at a temperature of 65 at 10 o'clock in the morning, it arrives at your laboratory at a temperature of 37 at 3 o'clock in the afternoon and has been kept at that temperature for 5 hours. Would that fact produce any kind of a change chemically in the water and if so what kind and to what extent?

A. I know of no change that was produced in the water.

Q. Would it, if it was kept 24 hours at a temperature of 37, when its source was 65?

A. Not that I know of.

Q. Would it if it was kept four days.

A. The water would change naturally on keeping, whether the temperature was high or low, because water—

Q. Answer the question.

1772 A. There would probably be a change.

Q. In what elements and in what respect?

A. The water if kept at a lower temperature than that at which it has been collected would very slowly have a conversion of nitrites into nitrates and of free ammonia into nitrites but this change would be very much less than if the water had been kept at the original temperature.

Q. But there might be a change?

A. There would probably be a change, a very slow one.

Q. And as a matter of scientific knowledge if the water was taken at its source at 65 and maintained for 24 hours at 90, there would be still other changes and more rapid?

A. Very much more rapid. The best thing we can do with water if we have to transfer it at all from the place where it is taken is to keep it in ice. If we let it go at the ordinary temperature the changes will be more rapid.

Q. It is less liable to change if kept in ice than if kept at its normal temperature?

A. It is less liable to change if kept in ice.

Q. Before the determination of the solids what did you do?

A. We evaporated 100 cubic centimeters of the water to dryness in an evaporating dish, in a weighed evaporating 1773 dish, and when it had gotten dry on the water bath we transferred it to an air bath kept at a temperature of 110 degrees centigrade. We allowed this dish to remain there for 15 or 20 minutes, then we took it out and allowed it to cool in a dessicator and then weighed it.

Q. 110 degrees centigrade would be how much Fahrenheit?

A. May I figure it out for you?

Q. Yes, glad to have you.

A. 230 degrees Fahrenheit.

Q. Does the Mississippi River water have considerable matter in suspension?

A. Yes sir.

Q. The waters in the reservoirs at St. Louis Water Works, have they considerable matter in suspension?

A. Yes sir.

Q. Now would that on being allowed to stand, settle?

A. Yes sir.

Q. How great a per cent?

A. That varies very much on the condition of the river.

Q. Well, in a general way, as a general matter of opinion, what would you say?

1774 A. It varies with the length of time it is allowed to stand in the reservoir and it varies from day to day according to the way they draw off the water from the settling basin.

Q. Now I will change the question. Take the water as it goes into the intake tower, has it very considerable solids in suspension?

A. It has.

Q. About what per cent as a matter of your general observation?

A. You mean the amount that settles out in the reservoir?

Q. No, taking a glass tube full of water at the Intake, 2 feet high, we will say, being allowed to stand for four hours, how much of the solid matter would settle?

A. Well I should say that 75 per cent of the solid matter would settle.

Q. Well what per cent of the total contents would that be?

A. Of the original weight?

Q. Yes of the original weight of the water.

A. At least 50 per cent.

Q. One-half of the entire weight is solids in suspension?

A. Well, I couldn't say that for a certainty. I haven't weighed that, I have never made that experiment. It is purely guess work.

1775 Q. You have observed these waters at least during these examinations and I want your opinion?

A. Well, I have observed that at some times of the year the water is very full of mud and at other times it is very much clearer and with reference to the water full of mud a great deal of this mud will separate out in a short time. At other times, when there is some slight turbidity, as when the water is low, then it doesn't get clear, even though we allow it to stand for 48 hours.

Q. Have you at any time, at any stage of the water, ever allowed it to settle with a view of determining the weight of the matters in suspension?

A. I have not.

Q. Now in addition to the solids in suspension—do you term that mechanical suspension or natural suspension—what is the term?

A. We simply say suspended matter.

Q. Now do you recognize that some other solids exist in mechanical form that would not settle?

A. Yes sir.

Q. What do you term those solid matters as distinguished from matters in suspension?

1776 A. We call those in solution.

Q. Now when you endeavor to obtain the solids in these waters which you examined, you evaporated a given quantity of water in a dish to dryness, I presume?

A. Yes sir.

Q. Then you put that dish in a water bath for what purpose?

A. I put it into an air bath.

Q. I mean into an air bath?

A. For the purpose of completely drying it.

Q. For the purpose of completely drying it?

A. Yes.

Q. What kind of a thing is this air bath?

A. It is a copper box with a door in front and an opening at the top for the insertion of a thermometer. It stands on four legs and is heated with a lamp, a Bunsen burner at the bottom.

Q. How long would you allow it to remain in this air bath?

A. Allowed it to remain 15 or 20 minutes.

Q. Then you took it out and weighed the dish?

A. After it had cooled off in the dessicator.

Q. Then you weighed it?

A. Then we weighed it.

1777 Q. Now, in that way you determined the solids?

A. By subtracting the weight at the end, subtracting from that weight the weight originally of the dry dish.

Q. Now then, when you made these examinations, did you ever put these solid matters so obtained in this air bath more than once?

A. No sir.

Q. And never longer than 15 minutes?

A. No sir.

Q. Did you never take them and put them back in the air bath after they had cooled in the dessicator to heat them again?

A. Ordinarily in a careful water analysis we did that.

Q. I am asking you as to this particular instance?

A. In the regular routine work we did not. We heated it uniformly for 15 to 20 minutes in an air bath, then we assumed they were dry and cooled them in a dissicator and weighed them.

Q. Did you have in this drying process of the solids, a stated time from which you did not depart, of the remaining of the dishes in the air bath?

A. Our time was from 15 to 20 minutes.

1778 Q. Did you have any particular time which you carefully and conscientiously adhered to at all times?

A. Yes sir.

Q. What was it exactly?

A. Well, from 15 to 20 minutes.

Q. Now that is a range of 5 minutes; was it 18 minutes or 17 1-2 or any one particular time?

A. It wouldn't make any difference.

Q. I didn't ask you whether it made any difference, excuse me. I am asking you for a fact.

A. We tried to get the time as near as we could to 15 minutes.

Q. But your 15 minutes was not an absolute rule which if transgressed was broken?

A. We made it as nearly 15 minutes as we could working with 14 samples a day.

Q. You don't understand me, was it 15 minutes or any other time, an absolute rule which if transgressed was broken and you discarded that sample?

A. Yes, that was the rule.

Q. That was the rule absolutely now, 15 minutes?

A. Yes sir.

Q. And if it went on to 17 1-2 minutes would you discard the sample?

1779 A. If the time was noted, if we noted that we had run over the time very much, why of course we discarded it.

Q. I don't care whether it was a minute over or one second or one hour, if you had an absolute rule what was it?

A. The absolute rule for the man who made these determinations was to dry the solids for 15 minutes in the air bath but I know he couldn't take them all out in the same instant.

Q. That answers the question. How many did you have in at any one time?

A. We could put in 14 at one time.

Q. And at the expiration of the time you took them out?

A. We took them out and it would take a man more than a minute to take them out.

Q. I am aware of that, but if you commenced to take them out at the expiration now of an absolute time which was not between from 15 to 20 minutes but was at 15 minutes precisely?

A. Well, he took them out as nearly 15 minutes as he could tell.

1780 Q. Now when you put your 14 samples into the air bath did your assistant, Mr. Fulks, make a note of the time when they went in?

A. He looked at his watch and noted the time when it went in.

Q. Did he make a memorandum of that upon some record?

A. Yes, he had a large card over this air bath where the daily numbers were put on. Each bottle of water which, of course, had a serial number and he recorded the number of the sample that went into each numbered evaporating dish and the time when these dishes were put into the air bath was put down on this card and then the time when they were taken out.

Q. The hour and the minute and the second as nearly as possible?

A. Yes sir.

Q. Now, you don't know the name of the persons who brought you the samples? They came in the regular course of this investigation to you. You don't know the names of the persons who brought the samples to you?

A. Yes sir.

1781 Q. They were brought by some Express Company?

A. They were always delivered to me by certain men that were employed by the City Chemist and I did know the names of those men at the time, there were always two of them and sometimes three, one man drove the wagon. There was a special team that was used, that was furnished by the city.

Q. Now, were those samples first brought to the City Chemist's office and then sent from the City Chemist's office to your laboratory?

A. There were always two samples brought from the railroad station to the City Chemist's office and there one sample was left and then the same team brought them to my laboratory.

Q. So that for each set of two samples that arrived at the City Chemist's office during this entire investigation, you received one?

A. I think that was the case.

Q. Now, did you receive any samples from the Missouri river.

A. Yes sir.

Q. How many?

A. We got a daily sample from Bellefontaine.

1782 Q. Any other place on the Missouri?

A. No sir.

Q. At any time?

A. No sir.

Q. Did you receive any samples from the Mississippi River at any place above Alton?

A. Yes sir.

Q. From what place?

A. At a point above Grafton.

Q. On the Mississippi?

A. Yes sir.

Q. Well, above Grafton give those?

GENERAL CROW: What river do you mean, the Mississippi?

MR. JOHNS: Yes. At any other place above Grafton you received none?

A. Not regularly. I think in the early part there were a few that came from a point farther up.

Q. What point farther up?

A. I don't recollect the name now. It is in my notes however and I can find out for you.

Q. Not a great many?

A. Not a great many.

1783 Q. Did you receive samples each day of the Mississippi water at Grafton or above?

A. Yes sir.

Q. During the times here that you have testified concerning?

A. Yes sir.

Q. You have testified concerning times from the 24th of January, 1900, to the 10th of October, 1900? And then into October and November, 1901, I think?

A. Yes sir.

Q. Was that all the analyses you made of these various waters?

A. Yes sir, that was one period during which we analyzed them systematically daily.

Q. Did you analyze them unsystematically or irregularly from Oct. 10, 1900 to January, 1901, for example?

A. We took occasional samples in our laboratory for analysis, simply for the purpose of instruction. The students made the analyses.

Q. You kept no record of those?

A. Yes, I have a record of those but they have not been presented in this report.

1784 Q. Did you make an examination of the waters of the Illinois above Grafton and analyze them between October 1900 and February, 1901?

A. No sir.

Q. Did you of the Illinois above Grafton between October 5, 1900 and the time at which you commenced in October, 1901?

A. No sir.

Q. None whatever?

A. None whatever.

Q. You never heard of any analyses of any waters above Grafton in the Illinois during that period in your laboratory?

A. Well, you say have I heard of any analyses?

Q. In your laboratory?

A. We haven't made any in my laboratory.

Q. When you made the analyses of the waters of the Missouri, during what period was it?

A. First from January 24, to October 10, 1900, and then again from October 1st to November 30, 1901.

Q. And that is all the analyses of the Missouri waters that you have made in a systematic way?

A. Yes sir.

Q. Did you prior to those, that is prior to the commencing of those analyses under the direction of the City Chemist, analyse the waters of the Missouri from any point?

1785 A. No sir.

Q. You never had?

A. No sir.

Q. Was one of the samples which you analyzed always from the water cock in the laboratory during this entire period?

A. Not during the entire period. The tap sample was taken daily at 11 A. M. Not during the first two months but along in Aprid 1900 we began, in April, May, June, July, August and September and then again in October and November 1901. We always took the samples from the tap in the chemical laboratory.

Q. Now is there such a thing as standard of potable water?

A. Not a very definite standard.

Q. If there is an indefinite standard is it the same at all places?

A. No sir.

Q. Must the potability of water be determined by the locality?

A. The character of the water, yes sir.

Q. Well, the character of the water is determined by the locality, isn't it?

A. Well, there are various kinds of potable waters. We classify potable waters in the surface waters and subsoil
1786 waters and deep well waters and spring waters.

Q. Now surface water I suppose you would call river water?

A. Yes sir.

Q. Now is there a standard of potability for surface water in the Mississippi river?

A. Yes sir, there is a standard of potability for river water?

Q. Now what is that standard of potability for river water?

A. Well that standard is given in our text books something like this: Free ammonia not above .06 parts per million.

Q. Is that six tenths?

A. No, that is six hundredths, that means if we find free ammonia in river water higher than that we are inclined to look upon it with suspicion.

Q. Now, as to some other element?

A. Then as to albuminoid ammonia. If it goes above .18 that shows that the nitrogenous organic matter in that water has approached the danger limit.

Q. That is .18 in the million?

A. Yes sir.

Q. Now, some other?

1787 A. If nitrites are in measurable quantities, that is if we can estimate the number of nitrites and express it in figures. If we do not simply know what it is but if we get enough so that we can compare the colors and determine the parts per million. If we do get .001 per million or .002 per million, that condemns the water, because it has gone beyond the limit. Measurable quantities of nitrites condemn the water.

Q. Anything above those numbers?

A. Yes sir, those are the chief characteristics.

Q. That renders the water having nitrites in it of a measurable quantity, potable or nonpotable, which is it?

A. Unpotable, I think.

Q. Now, as to any other element of pollution?

A. Well, if the chlorine runs higher than the average for that section of the country then we suspect sewage contamination.

Q. Now what is the average of chlorine in the Missouri river at its mouth?

A. May I look at my notes?

Q. Yes.

A. I have the averages for chlorine at Bellefontaine, which is at the mouth. The averages are from 15 to 16 parts
1788 of chlorine in the Missouri.

Q. Now a higher per cent of chlorine in the Missouri river than .16, did I understand it—

A. 15 to 16 it would run. In my record it runs from 11 up to 23.

Q. Now then at 23 the waters of the Missouri become unpotable?

A. No. If it runs very much higher than that we would say it was.

Q. Say it was 50.

A. Yes, we would suspect then sewage contamination.

Q. Well, if it was .1112 would it be potable?

A. Do you mean .1112 parts per million?

Q. Yes.

A. That would be very much less. It never has been that small, it always has more than that. It never has so small a quantity as that.

Q. Now it did have that on the 24th of January, if I recollect your notes, unless there is a mistake in the typewriting? That is the reason I asked you?

A. You have given me one tenth of a part per million.

Q. 1112.

A. That would be a little over one-tenth of a part per million.

1789 Q. Now, when you read the figures I think you read that very number as to the chlorines in the Missouri river off the Intake tower at the Chain of Rocks on the Missouri shore. What did that mean?

A. Well, if I read that it meant that there was a little over one-tenth of a part per million chlorine in the water. There is always more than that. It runs all the way from 10 to 23 parts per million.

Q. Could you look at your notes for the chlorine?

GENERAL CROW: Are you referring to the nitrates?

MR. JOHNS: No sir, to the chlorine.

A. I don't think I gave the chlorines for the Missouri shore in the direct testimony.

Q. If there is such a thing as that in the testimony it is a mistake in the amount, you think?

A. You mean of the chlorine at the Missouri shore?

Q. Yes.

A. I can give you the monthly averages.

Q. Excuse me. I don't care for that just now. If there was any such statement as that it was either a mistake of the stenographer or a mistake of the tongue here in giving it?

A. Yes, it must be a mistake.

Q. There is no such state as that occurring in the Missouri river? 1790

A. No sir.

Q. I want to go back a moment again in your analyses. When you in analyzing find color in the analyzed water, then you make a color to match it in another tube by adding a standard and fixed quantity?

A. Yes sir.

Q. How do you determine the color on the analyzed water?

A. We compare the colors produced in the Nessler tubes, for instance, with a similar set of colors made in similar tubes with known quantities of ammonium chloride solution. Then we match these colors by placing them over a piece of white glass. At the bottom of this rack—there is an expressly constructed rack for holding these Nessler tubes and for the scale, and at the bottom of this there is a piece of white glass that throws a white light up through the tube.

Q. How long were those tubes?

A. These tubes were about 11 inches from the bottom up to the scratch. I think about 11; the whole length of the tube was about 12 inches.

Q. You didn't use 2 foot tubes?

A. The tubes holding the color like the samples of water and also the tubes holding the standard color, were about eleven inches up to the mark and up to the top twelve inches.

1791 Q. You didn't use two sets of tubes in the examination of colors at all?

A. We used one set of Nessler tubes for the free and albuminoid ammonias and for the nitrites we had a shorter Nessler tube. That was about an inch in diameter and about six inches high.

Q. Now, I understand you to say that you made a determination by a series of experiments whether the waters of a given river are homogeneous?

A. Yes sir.

Q. The waters of the Mississippi for instance, at the Chain of Rocks, you can by a series of experiments, determine whether they are homogeneous?

A. Yes sir.

Q. That would be by taking the samples across the river so as to substantially make a cross section of the river?

A. Yes sir.

Q. How frequently would you take such samples if you were to determine the homogeneity?

A. We took the daily samples of water at the Intake.

Q. I am asking you of a supposititious case, Professor, how many samples across the river at the Chain of Rocks would you take to determine the homogeneity or lack of it?

A. Well, we took three samples daily.

1792 Q. Would you if you were to determine that thing and that only and when working for that purpose and that only, take more?

A. Well, it would depend upon how accurately we wanted to know the variation in the river at different points. You can get a very fair idea with three samples, one at each side and one in the middle.

Q. But if you wanted to be very accurate about it you would take a greater number?

A. If you wanted to know how it varied all the way over you would take a greater number.

Q. You actually took in the Mississippi river, with these experiments at the Chain of Rocks, how many?

A. Three every day, one at the Intake and one at each shore.

Q. Will you please examine your notes or tables for the free ammonia on the Missouri shore, the maximum or average and on the Illinois shore for July 1900? What I would like to have you do is to take it from the same paper you testified from.

A. I have got the Illinois shore here for 1900. The maximum free ammonia for the Illinois shore July 1900 occured in the fourth week of July and was equal to .0388 parts of nitrogen per million of water. This is the Illinois
1793. shore and the average for July was .0291.

Q. Now, look at the Missouri shore. You have an algebraic formula by which you determine the amount of water or relative amounts of two sources of water in a given place at a given time?

A. Yes sir.

Q. Do I understand you that that is the actual water in the actual proportions. For instance you arrive at a conclusion in a calculation here by this algebraic formula "that the proportion of the Missouri to the Mississippi was three-fourths or it was three-fourths Missouri water?"

A. Yes sir.

Q. Now do you mean to say that that is actual water or is that a supposititious or chemically conceived stream made for the purposes of the calculation?

A. That is made from these results and shows that water taken at that time contains three-fourths of the Missouri water and one-fourth of the Mississippi water.

Q. Now, won't you on a piece of paper take down this supposition, "let X equal the fractional part of the Illinois River above Grafton and Y equal the Mississippi River at Hartford. A equals the nitrites above Grafton .0257, B equals the nitrites at Hartford on the Mississippi, .0120
1794. and C equals .0071, nitrites Illinois shore Chain of Rocks." Now give me the value of X and Y?

A. Do you want me to figure the value for X and Y provided these rivers mix?

Q. No supposition about it, I want you to give me the value of X and Y?

A. Well, I can do that but it does not mean anything.

Q. Well, I want it at any rate.

A. Now assuming those waters mix and they do not.

Q. I simply want your conclusion as a mathematician on that given state of facts?

A. $X=\frac{.0049}{.0137}$—which is an absurdity.

Q. That is an absurdity?

A. The rivers do not mix and we don't have that quantity.

Q. That proposition is of itself then an absurdity, is it?

A. Yes, if you take these numbers in this way.

Q. Now, assuming X to represent a fraction of the Illinois River above Grafton and Y a fraction of the Mississippi River above Grafton and A the nitrites in the Illinois River above Grafton .0257 and B the nitrites in the Mississippi River above Grafton .025 and C the Illinois Shore at the Chain of Rocks, nitrites .071 for the same period. Now, give me the value of X and Y?

1795 A. About one-fifth.

Q. X is one fifth of Y?

A. Yes, X is one-fifth and Y is four-fifths. The Mississippi mixes four-fifths. It is pretty nearly that.

Q. Approximately?

A. Approximately, yes sir.

Q. Well, if the fact was independent of the algebra that the Illinois River at Grafton at that time was less than one-tenth of the Mississippi in volume, your mathematics are not of much account?

A. Well, it shows that as far as the nitrites are concerned one-fifth of the nitrites were furnished by the Illinois river and four-fifths furnished by the other.

Q. That is precisely to the point I want to bring it. Your algebraic formula does not represent the amounts of water at all?

A. They represent the amounts of water that are necessary to furnish that constituent to the Illinois.

Q. As a matter of fact it represents the proportion of nitrites in the water and does not as a matter of fact represent the volume of water distinguished from some chemical conception or the conception of a chemist?

A. It means that that proportion of the whole that much of the other water is required to furnish that much nitrites.

1796. Q. Now, isin't it a theory that you might as well assume nitrates as nitrites in that action?

A. You can take any one of our measured quantities in this calculation.

Now as a mathematical opinion, and I have not much, would not those proportions vary as one-fifth and four-fifths upon any other element upon which this calculation might be made?

A. They would vary as the other elements varied.

Q. So that it is a calculation of the comparison of polution as to a certain element and not a determination of the actual volume of water?

A. It is not an actual determination of the volume of water.

Q. What you meant to attempt to do with that and what you do as far as the mathematical formula is concerned, or algebraic formula, is to determine that if at a given point there are .0120 of free ammonia and at some other point a certain other number of parts and at a certain other point a certain other number of parts, these two confluent sources furnish a certain ascertained amount of free ammonia at the given point?

A. Yes sir.

Q. So that it is theory and not actual water?

1797 A. Yes sir, it is theory.

Q. Now, with the waters of the Mississippi and Illinois mixed bearing nitrites into the Intake Tower and therefore into the reservoir at St. Louis of four parts of nitrites for the Mississippi and one for the Illinois, and supposing at the same time that of the total water going into the Intake tower the Missouri furnished three-fourths and the Illinois and Mississippi combined one-fourth, which is your algebraic equation here, that was the conclusion at which you arrived?

A. Yes sir.

Q. Now, what proportion of the Illinois nitrites under those proportions got into the Intake tower, what amount?

A. Well, if the Illinois furnished one part to the four parts of the Mississippi, which it never does, the Illinois always furnishes more than the Mississippi, but making this assumption one-fourth of the nitrites furnished by the Mississippi would come from the Illinois, and since one-fourth of the nitrites would come from the reservoir, come from that, one-fourth of one fourth is one-sixteenth, therefore, one-sixteenth of the nitrites in the reservoir would come from the Illinois.

Q. Why do you say that the Illinois never does furnish one part of nitrites to three to four parts of the Mississippi?

1798. A. My analyses show and all the analyses that I have seen of the water at the mouth of the Illinois and Mississippi, show invariably higher nitrites, especially in the winter time. The Illinois having greater nitrites than the Mississippi.

Q. Certainly, but when one-tenth of the volume comes out of the Illinois of the volume out of the Mississippi to make a total at the Chain of Rocks then the proportion of the nitrites to the whole body is much less for the Illinois than for the Mississippi?

A. Yes the proportion that came from that, certainly.

GENERAL CROW: Let me understand. You and the witness don't understand each other. You mean the proportion of nitrites in the whole body of water, the combined waters at the Intake, that is what you mean?

A. Yes sir.

GENERAL CROW: Let the records show that is the proposition he means.

CROSS-EXAMINATION.

By Judge Springer.

Q. Professor Keiser, you have stated that you made certain analyses of the waters found in the Missouri River at Fort Bellefontaine?

A. Yes sir.

1799 Q. Have you given the result of those samples?

A. I have given some of the results.

Q. What result did you give, without saying what they were, just what ones?

A. I have given the averages for the chlorines but I have put on a chart that was presented the averages for free ammonias and albuminoid ammonias and nitrites.

Q. Averages compared with what?

A. Well the averages taken during the month of January 1900 and then compared with the averages taken during February and March of the same year.

Q. That table has not been submitted yet has it?

A. Yes sir.

Q. It wasn't read?

A. Yes sir, the map with these figures on was submitted. I have them here if you would like to have me read them.

Q. They have been put in the record have they?

GENERAL CROW: Yes, they were put in the record.

JUDGE SPRINGER: Then I only want to ask you about one. Did you make the averages of the results of those samples?

A. Yes sir.

Q. Could you state briefly the averages for the entire period of your examinations without going into detail?

1800 GENERAL CROW: At what point?

JUDGE SPRINGER: Missouri River, Bellefontaine.

A. I have here the weekly averages and the monthly averages.

Q. State the monthly average then at Bellefontaine and for the period?

A. For free ammonias or nitrites or what?

Q. First for chlorine.

A. Weli, the chlorines at Bellefontaine run as follows:

The average for	January 1900 was	23.5
"	February,	18.6
"	March,	12.1
"	April,	12.5
"	May,	14.5
"	June,	11.4

	The average for	July, 1900 was	11.2
	“	August,	12.8
	“	September,	16.3
	“	October,	11.4

Q. Now give the averages for those same months for nitrites?

A. The average for 1900 was:

	“	January,	.008
	“	February,	.014
1801	“	March,	.023
	“	April,	.018
	“	May,	.013
	“	June,	.003
	“	July,	.001
	“	August,	.001
	“	September,	.002
	“	October,	.002

Q. Now give the nitrates?

A.

January,	.415
February,	.592
March,	.965
April,	.485
May,	.484
June,	.418
July,	.462
August,	.435
September,	.381
October,	.560

Q. Now give the free ammonia?

A.

	January, 1900 average;	.135
	February,	.232
	March,	.144
	April,	.069
1802	May,	.083
	June,	.067
	July,	.055
	August,	.038
	September,	.068
	October,	.055

Q. Now give the albuminoid ammonias for the same period?

A.

January,	.363
February,	.395
March,	1.182
April,	.775
May,	1.484
June,	1.181
July,	1.556
August,	.842
September,	1.133
October,	1.382

Q. Did you make an analysis for the required oxygen consumed?

A. Yes, I have those figures, however I have not averaged those up for the months. I didn't consider the required oxygen of such great importance for the reason that the 1803 waters of the Missouri are always charged with a great deal of earthy matter and I found that the oxygen consumed or required oxygen had very little significance. The albuminoid ammonia is largely of vegetable origin and the oxygen consumed does not furnish us any very valuable information in this case as it would in other waters where the contamination is more of a sewage character. The Missouri River is largely charged with vegetable organic matter in contradistinction to that which we find in the Illinois river, and therefore the required oxygen does not furnish us any very valuable evidence so I have not made the averages, although I have the daily determination.

Q. Then I will not go into that. Did you ascertain the total solids per million?

A. Yes but I haven't got the monthly averages. I have them for every day and they are very high. They run very high.

Q. High in solids?

A. Yes sir.

Q. Will you give one or two as averages so far as you can?

A. I haven't them here.

Q. What is your recollection?

A. Well, they run sometimes seven and eight hundred parts per million and sometimes a thousand parts per million.

1804 The Missouri often is very muddy and taking it unfiltered and simply shaking it up we got an enormous weight of total solids.

Q. You stated in explanation of the fact that the chlorines run high in the Missouri River that there was some river in Kansas that was supposed to be impregnated with saline matter, will you state what that river is?

A. I am not personally acquainted with the exact source, but I have been informed by the City Chemist of the City of St. Louis, Dr. Teichmann, here, that one of the tributaries of the Missouri coming in at Kansas City has gone across salt beds in Kansas, and that is very highly charged with chlorine, and that is the reason for chlorine in the Missouri River.

Q. You don't know anything about that except what Dr. Teichmann told you?

A. No, sir.

Q. You never made any analysis then of this Kansas River water?

A. I have not.

Q. Before it came into the Missouri River?

A. No, sir.

Q. You have no opinion then upon the subject so far as that is concerned, simply what you were told by the City Chemist?

1805 A. Simply what I was told by the City Chemist, who I believe, has made these analyses.

Now, if it should appear by analysis that the river from Kansas coming in from Kansas City, which I believe is called the Kaw?

A. Yes, I think that's it.

Q. That is if it did not run any higher in chlorine than the waters of the Missouri River above that point then the theory as to cholorine constituents coming from Kansas would not obtain?

A. That is so, I agree to that.

Q. During the period to which we have referred, viz.: January 24, 1900, to October, 1900, can you tell or have you any data by which to determine, by which you did determine the volume of the water in the Missouri River as compared with the Mississippi and Illinois River?

A. I did not.

Q. You made no determination of that?

A. I made no determination.

Q. Are there any data of that kind?

A. Yes, sir; the records have been made and these records have been made by the City Chemist of St. Louis.

Q. They will be put in later, I suppose?

A. They will come later.

1806 Q. In making your analyses of the various waters to which you have testified for albuminoid ammonia, were the waters examined as taken from the river or after filtration?

A. They were taken in the unfiltered state.

Q. Were you furnished with any data by which you determined the volume of water in the Illinois River which was contributed by its tributaries the Kankakee, the Vermillion, the Sangamon and other rivers?

A. No, sir.

Q. As compared with that which came through the Drainage Canal?

A. No, sir.

Q. You are familiar with the general features of the Illinois basin drained by the Illinois River?

A. Yes, sir.

Q. In making the analyses to which you have testified here as to the condition of the water at Grafton above the mouth of the Mississippi River, you did not take into account any supposed pollution that might have been brought to the Illinois River by the entering of its tributaries?

A. No, sir.

Q. If the waters coming into the Illinois River from the Kankakee River above the mouth of that river should contain free ammonia and albuminoid ammonia and nitrites and nitrates in pronounced quantities, what would you say as to the effect of the mixing of that stream with the Illinois river?

A. They would tend to pollute the Illinois River.

1807 Q. And so with the Fox River coming in?

A. Yes, sir.

Q. And of the Big Vermillion and the other streams, known to empty into the Illinois River?

A. Yes, sir.

Q. If it should appear upon investigation and reliable data that more than half of the waters constituting the Illinois River at Grafton were contributed by streams entering that river other than the Drainage Canal, and that the averages for chlorine, free ammonia, albuminoid ammonia, nitrites and nitrates, were larger or equally as large in the tributaries as in the main river, what would you say or what would be your opinion as to the amount of pollution if any contributed by the stream itself and by its tributaries?

A. In that case the proportion of these impurities which came from the tributaries would form a fraction of the impurity of the Illinois River and the magnitude of that fraction would depend upon the relative volumes of the Illinois and its tributaries and it would vary as the volumes of those tributaries vary.

Q. Then in your conclusions as to the amount of pollution that is contributed to the Mississippi River at Grafton for the Illinois River, you take no account whatever of what might have come from the tributaries of the stream?

A. No, sir, I simply analyze the water as it is taken out of 1808 the mouth of the Illinois River.

Q. Then so far as your analysis is concerned, you charged up all the impurities that you found at Grafton to the Drainage Canal?

A. Well, in this way, as we ascended the river and we found the impurities increasing steadily, as we went up the river, I reasoned that if the impurities came slightly from the tributaries of the river the quantities of free ammonia and albuminoid ammonia and nitrites would be pretty constant all the way up the river and up through the tributaries if the waters were homogeneous, they would show that on analysis, but we found as we ascended the Illinois river that there is a very great increase all the way up to Joliet where the analyses showed the water to be diluted sewage.

Q. Increased in what elements or what particulars?

A. In free ammonias and nitrites and in chlorine and in albuminoid ammonia.

Q. Now, the results of your analyses at the various places to which you have testified, in those results you have not taken into consideration one of the important factors, the presence of chlorine?

A. Yes, we determined the chlorine at all points.

Q. It wasn't stated in your conclusions, was it?

A. No, we didn't make a tabulated table of that but on the record or daily analysis, the chlorines are given.

1809 I have read off in the record the monthly averages for chlorines at Lockport, Joliet and Peoria and the Illinois shore at Grafton and the Mississippi River at Grafton, also the monthly averages at Hartford, of the Illinois shore and Missouri shore and at Lockport and Joliet for 1901.

Q. What significance do you attach to the presence of chlorine in potable waters?

A. Chlorine in potable water comes from the salt that is dissolved in the water and there is always a certain quantity present in natural water.

Q. Now, if we find that a given water has a proportion of chlorine higher than this co-called normal chlorine we at once suspect sewage contamination, for the reason that salt, common salt, is used so extensively in articles of food and it would thus find its way with the sewage into the water?

A. Yes, sir.

Q. In making your various analyses of water to which you have testified will you state what was the standard of purity for drinking and domestic purposes of river water which you carried in your mind as your idea of what it should be?

A. The standard for chlorine or for the free ammonia?

Q. I am asking you separately for each of them. What was your standard in making these analyses as to the amount of chlorine?

1810 A. Well, since my analyses disclose that the Mississippi River averaged in chlorine from four to five parts per million above Grafton, and since below Grafton the chlorine suddenly jumps to 15 and 16 parts per million, I conclude that that may be taken as evidence of contamination as regards chlorine.

Q. What is that?

A. That the Mississippi River running four and five parts above Grafton suddenly jumped up to 10 or 12 parts below Grafton, that is evidence of a contamination by the Illinois.

Q. What do you fix then as the safe standard?

A. Then the safe standard for the Mississippi should be four or five parts.

Q. What do you fix then for the Missouri River?

A. The Missouri River, however, runs from 15 to 16 parts normally and we cannot use that standard very well with the Missouri. If the chlorine goes higher than 15 or 16 parts then it indicates contamination, but owing to the fact that the Missouri is charged with salt from the salt beds we are deprived from using this standard in judging of the purity of the Missouri river. We then fall back upon the nitrites and free ammonias and albuminoid ammonias.

Q. How about the chlorine at the Chain of Rocks at the Illinois shore, what is your standard?

1811 A. We find at the Illinois shore it runs higher in chlorine than the Mississippi river above Grafton.

Q. What is the figure?

A. The chlorine at the Illinois shore, Chain of Rocks runs higher and the averages are higher than the averages for chlorine for the Mississippi river above Grafton. We find, however, that the averages for chlorine on the Illinois shore, Chain of Rocks, are very nearly identical with the averages for chlorine at Hartford, which is above the mouth of the Missouri.

Q. What was that average, just one of them, please?

A. Well, at the Chain of Rocks the chlorines run from 8 to 10, whereas on the Missouri shore the chlorines run from 14 to 15 to 16.

Q. So it depends entirely on where the water comes from as to the potability of the water in reference to chlorine?

A. Yes, in order to use the chlorine standard we have to have the so-called normal chlorine, an idea of what the average of chlorine would be in water in an uncontamniated state.

Q. Then when you gave it as your opinion as to the potability of water coming from the Missouri river at Bellefontaine and the waters coming from the Chain of Rocks, the Illinois shore, you had different standards in your mind?

A. As regarded the chlorine, yes, but not as regarded the free ammonia and nitrites and albuminoid ammonia?

1812 Q. I will come to that later, merely as to the chlorine?

A. Yes, as to the chlorine.

Q. Now, will you give the standard which you had in your own mind for determining the potability of the various waters in examination in reference to the presence of nitrites?

A. Measurable quantities of nitrites indicate that the water is contaminated. If you have nitrites that you can measure and readily represent in parts per million it shows contamination of the water.

Q. Is that the opinion of all writers upon this subject?

A. Well, it is the opinion of a good many of them. There are variations, of course. And our own water is not always free from nitrites. We have measurable quantities present most of the time?

Q. Have you ever examined the reports of Professor Mallet of the Wilmington Board of Health?

A. Yes, sir.

Q. Do you know what he fixes as standard for potable water with reference to nitrites?

A. Yes, sir; I think I have copied his standard. I have them here among my papers.

GENERAL CROW: That is Professor Mason's book you read from?

JUDGE SPRINGER: Yes, sir.

1813 THE WITNESS: This work of Professor Mallet was done a number of years ago and he allows .0135 parts per million, although he states that the average for nineteen waters that cause disease was .0403 and Leeds' standard for American waters was .003, that is the allowable amount of nitrites, the maximum amount.

Q. The standard you fix was that if there was a measurable quantity that would condemn the water for nitrites?

A. Yes, a measurable quantity would be about .001 to .002, as I would put it, because nitrites show that fermentation changes are going on in the water and that bacteria are at work in the water and therefore it is dangerous water. It is water that is unstable, it is undergoing change constantly and good drinking water should show no nitrites?

Q. What is your standard for potability of water in reference to nitrates?

A. In reference to nitrates?

Q. I mean the standard which you use in making your comparisons in regard to the analyses you have made yourself and to which you have testified here?

A. Well, above five-tenths parts per million.

Q. How?

A. When water comes above five-tenths parts per million of nitrites it is to be regarded with suspicion.

Q. Is that the amount that you had in your mind when you
made your comparisons of the potability of the various
1814 waters to which you testified?

A. Yes, sir.

Q. Now, as to the standard dictated by you, in estimating the importance of the presence of free ammonia, what standard did you use for potable water?

A. The standard for free ammonia is that when it gets above .06, it is to be regarded as not drinkable, or rather polluted, that is .06 parts per million. That is the average I should say for good waters and when it gets higher than that we regard it with suspicion.

Q. It may, however, contain much higher quantities and still be potable?

A. It may be used as drinking water but it is dangerous.

Q. Now, as to the albuminoid ammonia?

A. Whenever it gets above three-tenths it is a suspicious water, it is unsafe.

Q. On page 62 of Professor Mason's book, he places the result of analyses of an excellent mountain stream that he himself examined and found that albuminoid was .0230 parts per million, showing there was no pollution, being a perfect mountain stream. Do you recognize that as being a possible amount.

A. You will find in that same book that he puts down the
average for polluted waters for albuminoid ammonias as .228
and for free ammonia .182. He says when you get above
1815 that it is to be regarded as bad water. For nitrites he
gives for good water .000. That means none and for polluted water .006 and for free ammonias .063 in good waters and

for polluted water .082. They are very nearly the same as these which I have used in my examination.

Q. Now, with reference to the amount of total solids, did you have a fixed amount in your mind as to what was regarded as safe?

A. I had no fixed amount in mind because our solids varied so very much in the Missouri River. In high water it is so heavily charged with mud that the total solids cannot be used in judging of the purity of the water.

Whereupon an adjournment was taken until 2:15 p. m., March 16, 1903.

1816 Met pursuant to adjournment March 16, 1903, at 2:15 p. m. at the Southern Hotel.

Present, same as at morning session.

PROFESSOR KEISER resumed the stand for further cross-examination, by Judge Springer, and testified as follows:

Q. Professor Keiser, Saturday in your testimony you had occasion to refer to a report by Professor J. H. Long, with reference to analyses made from water taken from the Illinois River in the year 1899, do you remember that?

A. Yes, sir.

Q. I want to call your attention to some portions of your testimony taken at that time. You stated that the samples which you took were of waters taken from the river above Peoria?

A. Yes, sir.

Q. But that you did not know from what point Professor Long's samples were taken?

A. No, sir.

Q. I want to call your attention to the fact that if you had observed these tables you would have seen it distinctly stated where they were taken. I will call your attention to that on page 24 of his report. You see the words "Peoria Narrows" on page 24, it says Narrows.

GENERAL CROW: That means above the sewage of the city, doesn't it?

1817 JUDGE SPRINGER: Yes, that is above the sewage of the city. You see the word "Narrows."

THE WITNESS: That is above the city, isn't it?

Q. Yes, that is above the city.

A. I wasn't certain about that.

Q. Down below that you see also Wesley. Wesley is between Peoria and Pekin and after the sewage of the city of Peoria has been received into the Illinois River?

A. Yes, sir.

Q. I call your attention to that for the purpose of calling your attention to another report.

GENERAL CROW: The figures he refers to of yours were made from samples taken from above Peoria?

A. Yes, sir.

JUDGE SPRINGER: All together his work. I mean he took no samples at the point of Wesley below Peoria.

THE WITNESS: No, sir.

GENERAL CROW: But there were samples taken below Peoria?

JUDGE SPRINGER: Yes, by Professor Long.

GENERAL CROW: Yes, and by Prof. Keiser, too.

JUDGE SPRINGER: I am talking about what he testified to at this time, at this particular time, isn't that right Professor?

THE WITNESS: Yes, sir.

Q. You were asked this question: "Give me the result of
1818 that Professor?" "A. The values before the opening
of the canal of free ammonia were 0.895 and after the opening of the canal 3.060 according to Professor Long, and according to my analysis 1.950."

GENERAL CROW: At what point was that?

JUDGE SPRINGER: That was above Peoria. Will you look at that where I read from and see if you are reported correctly?

GENERAL CROW: Wait a minute. Now let the record show that you are reading from the stenographer's notes of his evidence and then ask him if that is correct?

JUDGE SPRINGER: I am coming to that. Is that a correct statement of your testimony?

A. Yes, sir.

Q. Now, let me call your attention to this book from which you read on page 36, table of averages given by Professor Long. Do you see that table?

A. Yes, I have it.

Q. Please run your eye along the line from Peoria Narrows to the word Free Ammonia at Peoria. Have you got that?

A. Yes, sir.

Q. What was it?

A. It is printed here .0895.

Q. Now, that is correct. That is for 1899 before the
1819 opening. Now, look at the table of averages on page 44?

A. Yes, sir.

Q. Run your eye along the line from Peoria, Wesley until you strike free ammonia, what do you find?

A. 3.060.

Q. That is the way you gave it in your testimony?

A. Yes, sir.

Q. Now, I want to call your attention to the fact that that is the river below Peoria and not above Peoria at the Narrows as you compared it with?

A. Yes, I see that is Wesley.

Q. That is after the river has been polluted by Peoria sewage

A. That is the analysis that is given. There is none given there above Peoria, that is as near as we could come to it.

Q. Now, if you will look at page 64 you will see another table, that is the averages for the summer of 1900 by Professor Long. Cast your eye along from the Peoria Nerrows until you get the free ammonia. What do you find?

A. The free ammonia there in the summer is .21.

Q. And at Wesley?

1820 A. And at Wesley 1.62.

Q Now, if you take .21 as the average for free ammonia at the Narrows above Peoria for 1900 and compare it with 1899 as appears by this first table on page 36, what will you find?

A. Well, we are comparing then the summer water with the water that is found in the late fall of the previous year, and that is not a just comparison.

Q. Well, on his comparisons, though, you are making your statement. You stated the value before the opening of the canal of free ammonia was .0895 and after the opening of the canal 3.060, according to Professor Long and according to my analysis .0950. You put the comparison after the opening of the canal at 3.060, didn't you?

A. Yes, sir.

Q. Now, couldn't you have put it Peoria at the Narrows free ammonia 0.21?

A. Well for the reason that that is a further period of time. The canal was opened in January and we have our analyses that run up to November of the previous year. These first analyses come up to the end of November, 1899, and then the next analyses, the nearest analyses that are published, after the opening of the canal at the point nearest Peoria, give
1821 the value I have stated in my report?

GENERAL CROW: Published by whom?

A. By Professor Long.

JUDGE SPRINGER: For what year were his analyses?

A. The first analyses were those for 1899 on page 24 I think of this report, those were the first.

Q. That began in July?

A. That began in July.

Q. And ran until November 23rd?

A. And went down until November 23rd.

Q. It was for the year 1899?

A. That is the nearest we have to the opening of the canal.

Q. Now, beginning on the other table for 1900, it began with June 7th and ran until October 9th, didn't it?

A. Well, there was an analysis before that, immediately after the opening of the canal.

Q. But this is the one upon which .021 is based. That was based upon the analyses of water taken between June 7th and October 9th, 1900, practically the same periods in the two years.

A. Well, one is July and runs until the end of November and the other one begins in June and ends in October,
1822 there is considerable difference.

Q. A difference without a distinction, practically?

A. My experience has been that November is a month in which the free ammonias run very high and in June they run very low, so that if you compare them that way the chances are in favor of getting a very much higher result the first month before the opening of the canal and a much lower one after the opening of the canal, but if you will take all the analyses that are here published immediately after the opening of the canal, together with the spring, and then average them up you will get a truer value.

Q. Is this free ammonia?

A. Yes, sir.

Q. They were greater in November, then?

A. They are greater in November. They begin to run high in November, December, January and February and then they go down in the spring months and they are low in the spring and the water will probably appear very fair in the summer time when it is very badly polluted in the winter time.

Q. What I want to call your attention to is the fact that in this statement you compare the water at Peoria before the opening of the canal, of the samples taken above the Nar-
1823 rows and after the opening of the canal with the samples
taken below the Narrows after the Peoria sewage was in, and on that basis you show a large increase in free ammonias. Isn't that right?

A. There is shown a large increase there, but the analyses come as nearly together as they have been published.

Q. Well, what I want to get into your mind if I can, is the fact that this statement here as to the difference between the conditions before the water was turned in and afterwards, was based upon two very different conditions?

A. Samples were taken at different places, I understand, but they were taken not so far apart in point of time.

Q. Well, there is a great deal of difference between the Illinois River below Peoria and above Peoria.

GENERAL CROW: Do you mean before or after the opening of the canal?

JUDGE SPRINGER: Both. Now, if you will apply the averages taken above Peoria in 1900 with those taken above Peoria in 1899 you will find a large decrease in free ammonias after the canal is opened, will you not?

A. Yes, in the spring months, but no analyses were made above Peoria immediately after the opening of the canal, but

they were made below Peoria soon after the opening of
1824 the canal and then they show those high figures and our
analyses here made above Peoria soon after the opening
of the canal show also a high increase in the free ammonias, viz.: 1.6.

Q. Now, I will frame my question a little differently. You have made a comparison to show a large increase in free ammonia in the Illinois River at Peoria before the opening of the canal and afterwards and you base that upon Professor Long's statement made in 1899 between July and November 28th, and you have compared that result which was properly stated here at .895 free ammonias, with the conditions at Wesley found in the year 1900, and the average of the samples taken between June 7th and October 9th of that year, and upon this you base a conclusion that there was a large increase. Now, the table shows, according to what you have already stated—

GENERAL CROW: The table of Professor Long, do you mean?

JUDGE SPRINGER: The table of Professor Long. The average you quoted shows that you have taken the wrong plat, and that the actual figure should have been 0.21 which would have shown a large decrease in the free ammonias after the opening as compared before the opening?

A. I cannot agree with that statement—

1825 Q. I am not asking you whether you agree with that or not?

GENERAL CROW: You stated to him that he had taken Long's statement? He says he doesn't agree with that statement.

JUDGE SPRINGER: What I want to get at is the fact that this book shows from which you assume to quote, that there was a large reduction instead of a large increase which you contended for in your first examination?

A. I admit there is large reduction, if you compare with the months preceding the opening of the canal, the winter months, the summer months following the opening.

Q. That is not in this book. There is no comparison of that kind here. One begins in July 10th and runs until November 28th.

GENERAL CROW: If I understand you Judge, what you are trying to get him to testify to is, not what Professor Long's table shows itself but what his comparison of his figures with Professor Long's figures show, isn't that it?

JUDGE SPRINGER: No, what I want the record here to show is that in the statement that he made on Saturday that from Professor Long's statement he found a large increase. That was a mistake, and there was a large decrease.

GENERAL CROW: He didn't testify that Professor
1826 Long's figures showed there was a large increase.

JUDGE SPRINGER: Yes he did.

GENERAL CROW: He testified in comparison it showed an increase.

JUDGE SPRINGER: What I want to get in the record is, that Professor Keiser was mistaken in making this statement here and that he should if he was quoting from Professor Long, read from the line below and not above. Now, answer that question?

A. The record as published by Professor Long, gives his average values as I have stated them there, for the period of time from July until the end of November in 1899. Those figures are correct. Immediately following that he gives us an analysis made after the opening of the drainage canal and here we find Peoria, Illinois River and the averages which I have quoted, viz: .306 free ammonia, and that is also the average shortly after the opening of the drainage canal.

Q. What page are you reading from?

A. Page 41. There are no analyses given here for Peoria immediately after the opening of the Drainage Canal and this is the nearest I can come to it.

1827 Q. Well, is it fair to compare the waters at Wesley, that is below the sewage of Peoria with the waters above Peoria, which is above the sewage of that city, for the purpose of making any sort of a calculation or deduction?

A. I assume that that made only a very slight difference for the reason that the volume of sewage added by Peoria is comparatively small as compared with the bulk of sewage coming down the drainage canal.

Q. Then what I want to get into the record is that the figures 3.060 as to the conditions of the Peoria water after the opening of the canal were based upon the conditions you found at Wesley and not upon the same conditions that Professor Long based his upon, viz: at the Narrows above Peoria.

GENERAL CROW: What is that?

JUDGE SPRINGER: I want the record to show that his deduction was based upon the conditions at Wesley and not at the Narrows, isn't that true?

A. State it again.

Q. That your comparison for this period of the conditions of the waters at the Illinois River at Peoria before the opening and after the opening of the canal, were based before the opening upon the waters above Peoria and after the opening upon the waters at Wesley, below Peoria, isn't that true?

A. My figures—

1828 Q. Isn't that true or not? Answer that yes or no.

A. I have followed the report as given here.

Q. You have followed it as far as Wesley is concerned?

A. Yes, sir, as far as that is concerned.

Q. You took it at Wesley, then for comparison after the canal was opened?

A. I tried to compare the points as close together as I could get them.

Q. What I want you to state is the fact that your comparison was based on the condition of the waters in the Illinois River below Peoria?

A. Well, it is so printed in Professor Long's report.

Q. Now, with reference to the nitrites you stated that the nitrites before the opening of the canal (this means at Peoria) were 0.141 according to Professor Long. This is your statement and after the opening 0.060 according to Professor Long. Is that your statement?

A. Well, .141 before and afterwards .06, yes sir. It is from the same report.

Q. The statement as to conditions stated by Professor Long before the opening are for the year 1899 is correct, one after the opening is placed at .060 is incorrect and based upon conditions of the Narrows, was 0.12?

1829 A. Yes. May I say a word in explanation?

Q. Yes.

A. And so that in that table, while I quoted Professor Long's report for these values, I gave my own values for a point above Peoria and the estimation is not affected at all by this. I find that my own analyses made immediately after the opening of the canal, while not showing as high impurities as those quoted from Professor Long's report, at the same time show a marked increase of impurities during the months of February, March and April, immediately succeeding the opening of the canal.

Q. Now, with reference to the albuminoid ammonias at the same places. You stated that the albuminoid ammonias, before the opening of the canal were 0.572 by Professor Long and after the opening of the canal 2.210 by Professor Long, and according to your analyses 0.627. Now, the statement is correct as to the condition for albuminoid ammonia before the opening, viz: 0.572.

A. Yes, sir.

Q. Now, after the opening, you stated it as 2.210?

A. Yes, sir.

Q. Now, I want to call your attention to the fact that at the Narrows the albuminoid ammonia was 0.34 by Professor
1830 Long and showed a reduction at the same place in comparison according to Professor Long's table, and the albuminoid ammonia in the water at Peoria above the Narrows, after the opening as compared with the condition before the opening?

A. The same answer that I gave for the other applies to this, it is the same thing again. I have made a comparison of the analyses that Professor Long has published immediately after the opening of the drainage canal, that is the analyses that he made before, but I have not relied upon that analysis in deducing the estimation that there was increased impurity there. My analyses show the same thing and the water from my analyses was taken at a point above Peoria.

Q. Then what I want to get into the record is that these comparisons set forth in your testimony here were based in the first instance upon water taken above Peoria and in the second instance after the opening on the waters taken below Peoria. That is true, isn't it?

A. As regards Professor Long's figures but not as regards mine.

Q. I am not speaking of yours. Yours were not challenged at all. Of course this puts Professor Long's Report in a very unfavorable light.

1831 A. Well, I wasn't aware that Peoria made very much difference in the water.

Q. Well, there is another question. We will reach that after a while as to whether it makes any difference. You were asked this question, "What chemically does that show with reference to the ammonias, nitrites and albuminoid ammonia as to whether they have increased or diminished in the period covered? A. It shows that there was a very great increase." That is your evidence?

A. Yes sir.

Q. Now, having called your attention to the fact that you are basing your estimate upon waters taken at different places, viz: in the first period above Peoria and in the second below Peoria, if it appears from these books that you took your second period at a place below then your conclusion wouldn't be borne out by the fact as it appears here?

A. My conclusion is borne out by the fact that I made the analyses myself of water taken above Peoria and upon those analyses showing an increase of impurities I based the conclusion that there was increased pollution after the opening of the drainage canal?

Q. And you based that solely upon your own figures?

A. Upon my own figures and I also thought it was confirmed by Professor Long's own figures.

1832 Q. But you find you are mistaken in that?

A. I am not sure about that. I don't know about that.

Q. Well, the book shows that.

A. It simply shows that Professor Long's analyses were made at a point lower down apparently, at one season of the year, but I took the analyses which he had published immediately after the opening of the canal. That was the point in mind. As to the condition of the water after the opening of the canal compared with the water before the opening, that was my point and I have taken his results for the point nearest to Peoria which I could get and they show a marked increase in impurities.

Q. You overlooked this table on page 64, if you say you took the nearest you could get, because that table is published in the same work?

A. The table on page 64 shows the results for the summer months and they are very different. The water is very different then from what it is in November.

Q. Now, let me take Professor Long's report and call your attention to page 36.

1833 I call your attention again to your testimony of Saturday in which it is stated: "Albuminoid ammonia before the opening of the Canal was 0.572 by Professor Long; after the opening of the canal 2.210, by Professor Long, and according to my analyses, 0.627."

Now you have Professor Long's report before you, please point out in it the page upon which you found the first figure, 0.572.

That was in the year 1899.

ATTORNEY-GENERAL CROW: Well, you didn't include the free ammonia.

JUDGE SPRINGER: I am simply confining him to that one item. You can extend it to the others if you like.

ATTORNEY-GENERAL CROW: I don't wish to interfere with your examination. I just wanted to know what you were doing.

A. This is on page 36.

Q. Now running along the line there, you see Peoria Narrows and Peoria, Wesley, Illinois River?

A. Yes sir.

Q. Now which one of these lines did you take that data from?

A. I took it from Peoria Narrows.

Q. 0.572?

A. 0.572.

ATTORNEY-GENERAL CROW: Just put in the record
1834 where Peoria Narrows are.

The Peoria Narrows is three miles above the city of

Peoria, before the sewage of the City of Peoria has been received in the Illinois River. This place that was called by Dr. Ravold, Shady Beach.

Q. JUDGE SPRINGER: Now where did you find in Professor Long's report the statement from which you took the comparison of the condition after the opening of the canal?

A. I found that on page 44, where the averages are given for the spring work of 1900.

Q. And that was 0.221.

A. That was as nearly after the opening as these analyses are given.

Q. Now what is it at the head of that line, that you begin to draw from?

A. I find there Peoria, Wesley, Illinois River.

Q. So that was taken from Wesley, Illinois River?

A. 2.210. And then my own determinations upon which I base the conclusions gave .627; also an increase over the original for the same period of time.

Q. Now turn to page 64 of Professor Long's report and on the left hand column you will find the Peoria Narrows, and run along until you come to albuminoid ammonia. What do you find?

1835 A. Well, we find there .34, but I maintain that that is not a fair comparison.

Q. But never mind; I am not asking you whether or not you consider it a fair comparison. I am simply asking you what you found. You found .34.

If you took Professor Long's data for comparison it would show a decrease in free ammonia after the opening of the Canal, as compared with the period before the opening, taken from Professor Long's statement?

A. As Professor Long—as there are no analyses of the river above Peoria, immediately after the opening of the canal, although his analyses are near Peoria, namely, at Wesley, Illinois River, I compared with the nearest I could get.

Q. You have stated that several times. Please read the question.

Q. (Question read.)

A. Well, the figures that Professor Long gives us for the summer months are lower than the figures which he gives us for 1899, for the fall months.

Q. Well, is not that period covered for 1900, between June 4th and October 1st, according to page 5— It is the period June 7th to October 7th, Peoria analyses?

A. Yes sir, that is June 7th to October 9th.

1836 Q. That is the period upon which he bases his comparison for the period after the opening?

A. Yes sir.

Q. Now the same fact will appear in reference to the findings for nitrates, free ammonia and nitrates, would it not, as far as Professor Long's tables are concerned?

A. Yes, I have used his tables for free ammonia, nitrites and albuminoid ammonia.

Q. Then according to these two tables to which I have called your attention, Professor Long's tables show a decrease in these items after the opening as compared with before the opening?

A. A very long time after the opening, in the summer months.

Q. I know, but I simply ask you according to his tables— These tables show exactly when they were taken?

A. Part of his tables do it and part do not.

Q. Well, I call your attention to the dates which I have in mind, namely as stated in the record, and whether on those dates, the tables referred to by me do not show a decrease in his tables between the water before the opening and the period after?

A. Yes, if you compare his last tables with his first tables they do, but not if you compare his first tables with his
1837 second tables.

Q. Well, the second table has no other finding above Peoria has it?

A. No sir.

Q. Now then, take the first period on page 36 and read please the finding for Peoria, Wesley, of free ammonia, in Professor Long's tables, Illinois river?

A. Yes, I have it.

Q. Read it please,—free ammonia?

A. Free ammonia 4.35.

Q. Albuminoid ammonia?

A. 3.20.

Q. Nitrates?

A. 0.06.

Q. Nitrites?

A. 0.026.

Q. Turn to page 44 and read Peoria, Wesley, same place, Illinois River, and give me the findings for free ammonia; this will be after the opening, won't it?

A. Yes, this would be after the opening.

Well, here is 3.06.

Q. That is free ammonia? Now what is albuminoid ammonia?

A. 2:21.

1838 Q. And nitrates, what is that?

A. Nitrates .37. That is higher you will notice, than the other one.

Q. And nitrites?

A. Nitrites are .06, whereas, before they were .02, so that shows that in two determinations that the water is more impure —just what I contended for in these figures.

Q. Now you look at the oxygen consumed in Peoria in the first period, Wesley, on page 36, not filtered. Did you find that?

A. The oxygen in filtered, Wesley, 17.44; the oxygen not filtered, Wesley, 16.93.

Q. No.

A. Isn't that it?

Q. Oh, on page 44, you made the comparison for the different periods?

A. No, the oxygen, according to my book is 16.93 not filtered. Oxygen absorption at Wesley, 16.93 in the spring months, and 17.44 in the fall.

Q. Now you stated further in your testimony, as follows: I will read this and see if you can correct this error:

"Q. What chemically does that show with reference to the ammonias, nitrites, albuminoid ammonia, as to whether
1839 they have increased or diminished in the periods covered?
(Answer) It shows there was a very great increase.
(Question) Now, that table shows that from your figures alone

or the combined figures of yourself and Professor Long? (Answer): From the combined figures there is a marked increase here of the free ammonia, nitrites and albuminoid ammonia. (Question): Do Professor Long's figures show the same thing? (Answer): They do. (Question) What would that indicate, an increase of nitrites? (Answer): That would indicate an increase of pollution of sewage."

Now, in the light of the tables to which I have called your attention, do you care to modify those statements so far as Professor Long's statements are concerned?

A. Yes, these last tables show an increase in nitrites even compared with the spring work. Here we find that nitrites have gone up at the same point, Wesley, Illinois river.

Q. Yes, but I am speaking about the Narrows, above Peoria, about which you spoke before. Your own statements are all compared on the Narrows above Peoria.

A. The argument was based on Professor Long's figures. My figures show that there was an increase, regardless of Professor Long's results. My own figures are made after the opening of the Canal, gave an increase in free ammonia and al-
1840 buminoid ammonia, so I maintain this statement, there
was shown an increased impurity in the Illinois River after the opening of the drainage canal.

Q. That is your statement?

A. Yes sir.

Q. Now do you care to correct your statement on that point, or do you prefer to stand upon the position that you took before?

A. Yes, because we have just read in Professor Long's analyses at Peoria, Wesley, that they showed increased nitrites and nitrates, and the oxygen consumption was practically the same.

Q. Well, you made no comparison as to Wesley yourself?

A. I made no comparison myself, no.

Q. Therefore you cannot compare Wesley with your analyses?

A. No sir.

Q. Now just let us leave Wesley out and go back to the Narrows.

A. I wasn't aware that there was any certain degree of difference in making this comparison. I found the table on page 44 was the nearest one that Professor Long has published of results immediately after the opening of the drainage canal, and I took Peoria here as being the nearest point to that point where I had taken samples for analysis.

1841 Q. Then you don't know that—you didn't know that Wesley was located below Peoria?

A. I didn't know where it was exactly, and I didn't know whether the sewage of Peoria got into the river at Wesley—I thought it was considerably below, if anything. I didn't think it was right in the town of Peoria.

Q. Well, assuming that Wesley is below Peoria, and below the sewers of Peoria, would a comparison at that point for results be properly made with the conditions at the Narrows, above Peoria?

A. Not if they receive the sewage of Peoria, but it might have been taken there in the middle of the stream, where it would not have been caused by any sewers going into it from the town.

Q. Well, what I desire to have you correct, if you desire to do so, is the impression which you left here, that Professor Long's tables sustain your conclusions as to the increase of these conditions at Peoria.

ATTORNEY-GENERAL CROW: Well, name the conditions, nitrites and albuminoids—

Q. Nitrites, nitrates, and free ammonia and albuminoid ammonia, at Peoria before the opening and after the opening of the canal?

A. Well they show an increase in nitrites and nitrates.

1842 Q. That is a question. I have not asked about that, I am speaking about above Peoria, in the Narrows, according to Professor Long's table—I am not asking you to support them or to say that they are correct.

MR. WOERNER: What he wants to know is whether it is fair in your mind to compare the conditions above Peoria with the place where Professor Long—

ATTORNEY-GENERAL CROW: You got the impression from reading his testimony that he had testified there that Professor Long showed there was a greater pollution by reason of larger amounts of nitrites and nitrates, and albuminoid ammonia, and free ammonia above Peoria at what you call the Narrows, and what we call Shady Beach, after the opening of the canal, than there was before the opening of the canal; is that correct, Judge?

JUDGE SPRINGER: Yes.

ATTORNEY-GENERAL CROW: Now, if he testified about that, I don't remember.

JUDGE SPRINGER: Well, I just read what he said.

ATTORNEY-GENERAL CROW: Well, does that refer to that point?

MR. JOHNS: The only question in the discusion is that the gentleman read from the wrong line, and therefore the conclusion is wrong.

1843 JUDGE SPRINGER: Now I will correct my question then, so that you can answer it.

Having Professor Long's tables, as appear in his report, to which reference has been made, of analyses of water taken from the Narrows, above Peoria, before the opening of the Canal and after the opening of the Canal, don't his figures show that there was at that point a decrease in free ammonia, albuminoid ammonia, nitrates and nitrites, in the year 1900, after the opening of the Canal, as compared with 1899, before the opening of the Canal?

A. Profesor Long's report contains—

Q. Wait now? Can't you answer that Yes or No, whether this report does not show that at the time. That is all I want to know and get into the record.

A. Well I maintain—

Q. Well, never mind what you maintain. Is that report true?

A. For a portion of the year it is true, and when the spring rains came and there was a heavy dilution, the water shows an improved character, but it didn't show that improved character according to my analyses, immediately after the opening of the canal.

Q. Well now, I wish you would answer that question, because I want to do Professor Long justice.

1844 I am not asking you to state anything that you haven't got before you, and these tables show exactly the periods covered, and do not require any explanation as to the periods covered. It is in the book.

I am asking you to state whether Professor Long's tables as published in this report, do not show that the analyses of water taken at the Narrows above Peoria, before the opening of the Canal, show a greater amount of free ammonia albuminoid ammonia, nitrates and nitrogen, than was shown afterwards?

MR. WOERNER: The complainants object to the insistence of the counsel for the defendants for a Yes or No answer, on the ground that the witness has stated that the same is not susceptible of a direct answer without further explanation.

JUDGE SPRINGER: Well, here is the book before him. Anybody can see whether that is so or not.

MR. WOERNER: You ask him whether it shows the condition before and after the opening; it might show the condition 100 years before and 100 years afterwards.

ATTORNEY-GENERAL CROW: You see his very answer conveys the reason of the objection. He says one season it does show that and at another season it does not.

JUDGE SPRINGER: Will you answer that now?

In order to relieve the witness of any chance of evading 1845 this question—

ATTORNEY-GENERAL CROW: Hold on now I object to—

JUDGE SPRINGER: Well, I will withdraw that statement.

Q. In order to direct the witness' mind to the question that I desire him to answer, I call his attention to page 36 of professor Long's report. Now that contains the averages at Peoria from July 5th to November 23, 1899, is that right?

A. Yes sir.

Q. Well, now, taking the averages found for free ammonia, albuminoid ammonia and nitrites and nitrates, at the Narrows, above Peoria, from samples of water taken during that period, namely, from July 5th, 1899, to November 23rd, 1899, compare those averages with the averages on page 64 for the summer of 1900, taken at the same place, namely, at the Narrows at Peoria above that city, during the period from June 7th to October 9th, 1900, do they not show that for free ammonia, albuminoid ammonia, nitrites, and nitrates, there was a material reduction in the latter period as compared with the former period?

A. Yes sir.

MR. WOERNER: Now, Judge, if you have no objection, we would like to have the witness say whether he wants to explain that answer or not.

1846 JUDGE SPRINGER: I am perfectly willing he should do that. If he desires now to explain—if you desire now to explain your answer, you may do so.

A. I wish to state that we are now comparing analyses of waters made at different seasons of the year. We are comparing analyses made in the fall of the year, from July down to the end of November, when the results are apt to be low. With the analyses made in the early summer, throughout the summer when the rivers are apt to be swollen with the rainfall, and therefore it is not altogether a good comparison, and in my work, I was not endeavoring to establish the yearly value; I was endeavoring to determine what the effect of the opening of the canal was, and for that purpose I compared with the analyses made immediately after the opening of the canal, and they are published on page 44 of Professor Long's report, and I found my own analyses showed an increase immediately after the opening, taking analyses as near as we have them to the opening.

Q. We now see that you refer to the samples taken below Peoria, do you not?

A. Well, not in my own analyses.

Q. Oh, in Professor Long's?

1847 A. Professor Long's were taken below, but he gave none of the points above. This is the nearest we could come to it.

Q. Now I want to call your attention—in your testimony on Friday you were asked this question:

(Question): Now how does the water in the Missouri river at Bellefontaine, compare with the water of the Mississippi river above the mouth of the Illinois river as being wholesome?

(Answer): They are both fairly good streams from a sanitary standpoint.

Is that correct?

A. Yes sir.

Q. Are we to understand from that that you regard the waters of the Missouri river as suitable for the water supply of a city?

A. Yes sir. It is not as good as it might be, but still it can be used.

Q. In your testimony this morning you were asked as to your standard of purity for river water. Do you remember that?

A. Yes sir.

Q. Well, without repeating that answer, I want to ask you whether you did not state that if there was an ascertainable amount of nitrites in the river water, that it was to be condemned?

A. To be regarded with suspicion, yes sir.

1848 Q. Regarded with suspicion for potable purposes?

A. Yes sir.

Q. Now in your testimony on Saturday last, you were asked: (Question) Now have you made any comparison of the samples taken at Bellefontaine in the Missouri river?

(Answer): I have also made a table of the conditions of the water in the Missouri river at Bellefontaine.

(Question): Now where is Bellefontaine on the Missouri river with reference to distance from the Intake of the waterworks at St. Louis?

(Answer): It is 14 miles from the Intake of the St. Louis waterworks by river, but it is above the mouth of the Missouri river. In order to get the idea of the condition of the water in the Missouri river during this same period, immediately before and after the opening of the drainage canal I have taken the average of the analyses of the Missouri river water from January, 1900, and I find that before the opening of the canal that free ammonia was 0.135, and after the opening the average for February was 0.148. The nitrites before the opening were 0.008, and after the opening 0.014.

The albuminoid ammonia before the opening was 0.063, and after the opening 0.395."

Now do not these conditions in the Missouri at Fort Bellefontaine show, according to the standard which you laid down

this morning, that the waters at that point are not suitable
1849 for drinking purposes?

A. During that period of time for which these analyses were made the nitrites ran high and the water was to be looked upon with suspicion, during the summer, however—

Q. Wait a minute. I am coming to that after a while.

ATTORNEY-GENERAL CROW: Let him put that in. He is answering the question.

Q. JUDGE SPRINGER: Go on then?

A. Well, during the summer the nitrites are very low, and sometimes you can measure them, and with that amount I say that the river is a fair stream. It is not as good as we would like to have it, but still—and during the winter months, I admit that it is to be looked upon with suspicion according to the standards that I have given.

Q. Well, not suspicion only, but according to the standards you gave, it should be rejected as polluted, should it not?

A. Yes, it ought to be rejected in its unfiltered state, according to these figures.

Q. And during what months in the winter do these conditions prevail usually?

A. Well, during the cold season of the year, in November, December, January, February and March, along when the spring
rains come the nitrites fall, and in June, July and August,
1850 they are low. Sometimes—well sometimes we get merely
a trace.

Q. Well, what would you say then of a source of water supply for a great city, that four months of the year the water was unfit for use, and they were compelled to take it always from the same place?

A. Well, I should say it ought to be filtered.

Q. It ought to be boiled in addition?

A. Boiled anyhow; you can filter it or boil and filter too.

ATTORNEY-GENERAL CROW: And stop sewers from running into it too.

A. Yes.

Q. JUDGE SPRINGER: How does the water compare at the point known as the Missouri shore, Chain of Rocks, in your examinations or analyses, with the water at Fort Bellefontaine in the Missouri river?

A. They are very similar.

Q. They are very similar?

A. Yes sir.

Q. Is it your opinion then that the waters at the Chain of Rocks, Missouri shore, as stated in this investigation, are substantially the same?

A. Of course, there are variations from day to day, but taking it altogether, they are substantially—the water there 1851 is substantially Missouri river water.

Q. How far out do you know from the shore, is that place at which the samples were taken?

A. You mean the Missouri shore samples?

Q. Yes, from the Missouri shore, how far from the land?

A. Not very far out.

Q. How far would you say?

A. I don't know just how many feet. They were taken under the instructions of the city chemist.

Q. He will be able to state that?

A. That will be stated.

Q. Dr. Ravold stated two or three hundred feet, I think.

ATTORNEY-GENERAL CROW: Oh no; not those samples.

JUDGE SPRINGER: I think the sample men stated two or three hundred feet.

THE WITNESS: I don't know exactly where they were taken.

Q. How far did you say the Intake tower was from the Missouri shore?

A. I believe it is about one-third way across the river.

Q. Fifteen hundred feet?

A. Fifteen hundred feet.

Q. How far would that tower have to be moved inward in order to put it at a point where it would take Missouri river water only?

A. I asked that same question of the water commissioner, 1852 and at the same time asked him why he didn't take the Missouri river water, and he informed me that it was necessary to have the tower out as far as this because in dry weather the river is so low that it is impossible to get enough water for the city without having the tower out at its present position; that at low water, when the rivers got low, there is not enough water any further to the Missouri shore than the present position of the tower.

Q. Then in low water, wouldn't the Missouri river be further from the shore proper?

A. At low water the water falls and the volume in the Missouri is very low, and we get much more Mississippi river water, so that it is necessary to have the tower out at least as far as it is now.

RE-DIRECT EXAMINATION, By Attorney-General Crow.

Q. Now Professor, I believe Judge Springer referred to a table of Professor Long's there, made from analyses taken at a point he calls Wesley, below the city of Peoria, before and after the opening of the drainage canal, is that correct, did he refer to that kind of a table there?

A. Yes sir, he did.

Q. I will ask you to state whether or not that table does
1853 show that there is an increase or decrease in any of the
nitrites and nitrates before and after the opening of the drainage canal, and if so was the increase afterwards, or did it show the greater part before?

A. This table shows an increase at Wesley, Peoria, for the nitrates after the opening of the canal and also for the nitrites after the opening of the canal at Peoria, Wesley, comparing the results of analyses made at that point in July, from July to November 30, 1899, with those made at the same point from March to April, 1900, show an increase in those two figures.

Q. Well, is that the table of Professor Long's?

A. Yes sir.

Q. Now did Professor Long make any analyses of the waters in the Illinois river at what Judge Springer terms the Narrows, or Shady Beach, above Peoria, before and after the opening of the canal?

A. He made some before and, and there are none given immediately after the opening of the canal. There are some given in the summer of 1900, from June to October.

Q. Now do the seasons of the year affect or cause variations in the chemical constituents of running waters in rivers like the Illinois, the Mississippi and the Missouri?

A. They do, and very greatly.

1854 Q. Now the analyses you state that Professor Long made before the opening of the canal were made in what months?

A. Before the opening of the canal, the analyses were made in July, August, September and October.

MR. WOENER: Was that before?

A. This was before.

The analyses began July 5th, 1889.

MR. WOERNER: 1899?

A. It should be 1899. That is a mistake in print there; it should be 1899, and they go down to November 23rd.

ATTORNEY-GENERAL CROW: Beginning in July and going to November 23rd?

A. 1899, yes sir.

Q. 1899?

A. Yes sir, although it is printed 1889, it should be 1899.

Q. Now during that period of time what would be the effect, ordinarily, of that season of the year on nitrites, free ammonia and nitrates in the river?

A. Well, that is the season of the year when we are apt to have dry weather, or drouth and I should imagine that during that season of the year the water would be low and I should think that that would have the effect of increasing the quantities of free ammonia and albuminoid ammonias, and nitrites in the water. In other words, at that season of the year I would 1855 expect to find rather high values for free ammonias, nitrites and nitrates.

Q. What season is that?

A. In the season of the fall and going down into the cold weather at the end of November.

Q. Well now, from a chemical standpoint, from the standpoint of a water analyst and as a chemist, is it fair to make comparison between the spring months and the summer months?

A. No sir.

Q. Over the same area of water in a running river?

A. I don't regard it as fair.

Q. For what reason?

A. For the reason that in the spring months we have heavy rain-falls; we have the melting snows and ice in the head waters of these rivers—we have an opportunity in the Missouri river flowing past St. Louis—

Q. You mean the Mississippi?

A. In the Mississippi, yes—coming from the head waters of the Missouri and likewise in the Mississippi proper, the rivers are apt to be high. We have a heavy rainfall as a rule in February and March and April, and then in the spring there is high water. Analyses then would show very much less impurities.

Q. Why?

1856 A. On account of the great dilution.

Q. The impurities then are not removed, but there are simply just a given amount scattered throughout a larger volume of water?

A. Yes sir.

Q. And therefore in a gallon of water at that time of the year you would perhaps not find as much impurity as you would in a gallon in August?

A. No sir.

Q. Now considering then the seasons of the year at which this table Professor Long has made, to which Judge Springer refers, would you consider that, as a chemist, a fair comparison from which to determine the standard of purity of the water in the Illinois river in deciding the question as to whether it was more pure before the opening than it was after the opening of the drainage canal?

A. I think these two tables are not strictly comparable. I think the important work should be added in, namely, the analyses, page 44, the averages should be struck for the whole time during which analyses were made, in drawing up the final averages only the summer months and spring were taken into consideration, and not the work that was done after the opening of the canal, namely, January work. The February, March and April work was not included in striking those averages.

1857 Q. Now Professor, do you know whether the analyses upon which these tables of Professor Long were based, were made from samples taken daily or from samples taken weekly from the Illinois river, during the period of time covered by those tables, or does that report disclose?

A. According to this report the samples were taken weekly, or approximately weekly, namely, we see here Peoria, the Narrows, June 7th, 14th, 21st and 26th—those are weekly samples, and then there is a break to July 10th, 17th, 24th, 31st. They are practically—approximately weekly, with few exceptions.

Q. Now your samples were daily samples?

A. Yes sir.

Q. Now as a chemist and water analyst, I will ask you if there is any difference in the value of the result of the analyses that are made daily and those that are made weekly from the waters of a running river?

A. Well, the daily samples of course, enable you to get a very much better weekly average than simply taking one result.

Q. Well, they approach very nearly the continuous condition of the stream?

A. They do.

Q. Then are they regarded as the better for the test as to the purity of water—the daily better than the weekly analyses? 1858

A. They are.

Q. Now, Judge Springer asked you a hypothetical question, and the result of the question was to draw from you an answer as to whether or not, if the Ottawa and the La Salle, or rather the Vermillion and the Kankakee and all the rivers that run into the Illinois river were highly polluted; if it would not have an effect upon the pollution of that stream, and of course you said yes.

Now I show you here in a book, called "The Illinois State Board of Health," published, I believe by the State Board of Health of Illinois, and I suppose being the book that Judge Springer read from—you may examine it and see. Turn to page

64, Professor Long's report, examine that and see if that is Professor Long's report there?

A. Yes sir, it is.

Q. As to what?

A. That is as to the condition of the Chicago, Lake, Bridgeport, Illinois and Michigan Canal, Western Avenue, Drainage Canal—as to the condition of the water at all these points.

Q. Well, what water—the waters of the tributaries of the Illinois?

A. Some of the tributaries of the Illinois, and the Illinois itself.

1859 Q. Now please examine that table and if you can, state from that table whether or not Professor Long's report there in May, discloses that the tributaries of the Illinois which he reports there, are more polluted than the Illinois river itself?

A. Well, if we take one example here, the Kankakee river, Wilmington, and run across the averages, we find that it is in very much better condition than the Illinois river. We find that it is not as highly polluted. Free ammonia is only .1, and albuminoid ammonia only .46; nitrites .06.

The Fox river—if we run across for the Fox river, we find free ammonia .1100, whereas, the Illinois river at the same place —Ottawa—is .8. We find nitrites, none in Fox river at Ottawa, whereas the Illinois river, Ottawa is .9, almost a unit, and the nitrates are .02 for the Fox river and for the Illinois river .37, so I conclude from that that the tributaries are very much purer than the Illinois.

Q. At least that you have encountered there and examined there in that table?

A. Yes sir.

Q. What was the date of that examination and report of Professor Long?

A. This is from June until October, 1900.

Q. Well now, at low stages of those tributaries that you 1860 have mentioned there as being less polluted, according to that report, than the Illinois river, would the pollution that would come from them affect the Illinois river much?

A. The analyses show that the Illinois river is very much more polluted than any of its tributaries, and at low stages of course less water would flow in.

Q. Now, I have here in my hand a preliminary report to the State Board of Health of Illinois, by Professor John H. Rouch, M. D., secretary.

There are two appendices—one, chemical investigation of the water supply of the Illinois, by Professor J. H. Long, and the other, Illinois Basin and its relation to sanitary engineering, by L. E. Cooley, civil engineer.

Turning to page 15, I find that Professor Long, in a note paged to table 7, states:

"From table 7, it will be seen that the amount of organic matter in this water as indicated by albuminoid ammonia and oxygen consumption, is quite large, and as both are undoubtedly chiefly of vegetable origin, its effect should not be lost sight of."

This refers to the table giving the physical conditions and constituents of the Kankakee river.

I will ask you to examine that table and see if it bears out the statement that Professor Long makes?

1861 MR. JOHNS: This is objected to for the reason that it is not re-examining and the tables and statements will show for themselves.

ATTORNEY-GENERAL CROW: Well, we certainly have a right to re-examine him as to matters that you bring out. We didn't examine him on that in chief. You brought out the matter of the tributaries.

A. Compared with the values for the Illinois river, there is very much smaller free ammonia and albuminoid ammonias. For instance, they only run up to .1—free ammonia .1, and the Illinois river running much higher.

Q. Now I show you here a report of the Illinois State Board of Health: Advance Notes of the Sanitary Investigation of the Illinois River and its Tributaries. Springfield, Illinois, 1900, with special reference to the effect of the sewage of Chicago on the Desplaines and Illinois river prior to and after the opening of the Chicago Drainage Canal. On page 34 thereof we find a table of averages of chemical constituents of the waters of the canal at Bridgeport, at Lockport, at Joliet, Wilmington, and then the Illinois river at Ottawa, and Peoria, and the different

streams that come into the Illinois, and I will ask you to take that, examine it, and say if you can determine from that table whether or not the tributaries there are less polluted, as shown by the nitrites, free ammonia and nitrates they carry, than
1862 that of the Illinois river?

MR. JOHNS: Objected to for the same reason as given in the objection to the preceding question.

A. The nitrites run very much lower. The free ammonias are also very much lower than of the Illinois river.

This holds for Wilmington and for Ottawa, on the Fox river, and for Havana on the Spoon river, and for Brownings. The free ammonias, and the nitrites, and the chlorines are all very much lower in these tributaries, than in the Illinois.

Q. Do you know, Professor, as to whether or not there are any large cities or towns whose sewage out-falls are into the—in any of the tributaries of the Illinois river below where the canal—the Drainage Canal, joins the Des Plaines river?

A. I do not. I know of no large towns that run sewage into the tributaries of the Illinois.

Q. I believe you said, however, you are not personally, by having passed over the territory, familiar with that drainage area?

A. No sir.

Q. The city of Springfield, Illinois, must be on one of these tributaries, I suppose?

MR. JOHNS: It drains into the Sangamon. That is a city of considerable size, I believe 20,000 to 25,000 people.
1863 It has nearly 50,000 with its suburbs.

Q. ATTORNEY-GENERAL CROW: Well, if most of the drainage from the tributaries of the Illinois, into the Illinois were what we would call the rural character—of rural character, that is to say, towns not having sewers, and the usual drainage from the farms—would that be any different in its effects on the water than if there came into those streams and tributaries sewage flowing through sewers from larger cities and towns?

A. Yes sir.

Q. What would be the difference, if any?

A. Well, we would find high chlorine, for instance. Now, we do find low chlorines in these tributaries that flow into the

Illinois—we find low chlorines, and we also find low free ammonia, whereas in the Illinois itself there is a higher free ammonia, and similarly with the nitrites—the nitrites in the tributaries are low.

Q. Now, chemically, does this indicate anything to the water analyst, as to whether the origin of organic matter in water is of vegetable or animal source?

A. Yes, it indicates that the organic matter is of vegetable source when we have low chlorines and now nitrates, whereas, when the chlorines are high, and the free ammonia is high, and the nitrites high—those three things together indicate animal sewage.

1864 Q. Now, Professor, Mr. Johns asked you the question as to whether or not your analyses made to determine the quantity of Mississippi and Missouri river water that came into the Intake of the St. Louis waterworks, was an actual measurement, scientifically made, of the amount of water of the two respective streams, the Missouri and the Mississippi, that came into the Intake of the waterworks at that point, and I will get you to state now, whether or not it was such a scientific measurement?

A. It was a scientific measurement, calculated from the measured quantities of nitrites in the water.

Q. Now is that the usual and ordinary method that water chemists use for the purpose of determining the relative amounts of two streams, whose waters have commingled at a given point?

A. It is.

Q. Now did that analysis thus made by you, determine chemically the amount of those waters?

A. It did.

Q. Now was that made for the purpose of determining the volume of water that flowed down the river from the Mississippi, and the volume that flowed down from the Missouri, as they commingled together in passing the Intake?

A. It was made for the purpose of tracing these impurities that I found in our reservoir water, to their origin.

1865 Q. Well then, a chemical analysis of water does not constitute the measurement of the volume of the flow of the water?

A. No, sir.

Q. Or body?

A. No sir.

Q. Well, doctor, the analyses as made by you determine the quantity of pollution as contributed by the two streams?

A. Yes sir.

Q. Is the chemist able to determine that from this method of water analysis?

A. Yes sir.

Q. Now isn't it a fact, is it a fact that the actual volume of water does not necessarily correspond with the volume of pollution where two streams commingle—from the respective streams.

Do you understand my question?

A. Not exactly.

Q. Well, I will try to make myself a little more plain. Suppose where the Missouri and the Mississippi come together the water of the Missouri was about one-third greater than that of the Mississippi—but the Mississippi was polluted twice as great as the Missouri at the point of confluence. Then would the amount of pollution found by water analyses below the junction
of the streams, correspond necessarily with the relative
1866 volumes of the two streams at the point of confluence?

A. No sir.

Q. Why?

A. It would show rather than the volume of the streams, it would show us the proportion of impurity which came from each of the streams.

Q. And that is just what the water analysts can do?

A. Yes, that is what we are for.

Q. That is the value of the analytical determination of the commingling waters of the two streams?

A. Yes sir.

Q. And that was the object of making this examination?

A. Yes sir.

Q. Now Judge Springer asked you, I believe, if professor Long's figures did not disclose—the tables that he made—two analyses, one before and one after the opening of the Drainage Canal at Shady Beach, above Peoria. Can you take those tables and tell me whether or not he did make any such analyses at any time, without reference to the season of the year, just so it was before or after?

A. He made analyses at Shady Beach in the summer of 1900.

Q. What months?

A. In the months of June, July, August, September and up to October 9th.

Q. Now did he make an analysis at the same point prior
1867 to the opening of the canal, if those tables show that fact?

A. These tables show that he made analyses for the Narrows from July to November, 1899—for Peoria at the Narrows, July to November 30th—practically December 1st.

Q. 1899?

A. 1899.

Q. Now Mr. Johns asked you this morning as to whether or not fifteen minutes was the standard of time you would set for leaving the dishes in the receptacle in to which you placed them—the air bath, I believe?

A. Yes, air bath.

Q. Now I will ask you if it matters materially as to the practical result, chemically, as to whether they are left in there exactly 15 minutes, or 18 minutes or 20 minutes?

A. No sir, it is of no significance. The idea is to heat them up until the water is driven off. Now the water is practically all off when we put them in there, and we simply heat to make sure for about fifteen minutes, that the moisture is driven off, and twenty minutes or an hour wouldn't make any difference.

Q. Now Professor, I will ask you, do you consider the water, commingling of the Missouri and the Mississippi, as it comes into the Intake of the St. Louis waterworks, since the opening of the canal, is a safe, sanitary water for the use of cities of this size?

1868 A. I do not.

Q. I will ask you to state if you personally use the same without filtering it or boiling it?

A. The water that I drink at my house is all boiled and filtered.

Q. Now Mr. Johns also asked you about some assistants you have had or did have, in the conducting of these analyses. I will ask you to state as a practical chemist, whether it is possible for a man to conduct twelve or fourteen analyses of water a day through a period of time, by himself?

A. No, I regard that as a physical impossibility, for one man to make fourteen determinations in a day, or even a smaller number than that.

Q. And as a practical proposition of analyses of waters in quantities of this kind, twelve or fourteen samples made daily over a period of months, must be conducted by more than one man?

A. Yes, and they can be conducted with very much greater efficiency by having trained assistants who do certain determinations day after day. They acquire skill in their routine work and their figures then give very reliable results, because they are strictly comparable, whereas, if one man attempts to do everything he does not acquire the same skill in all the processes, as he would if he confined his attention to one determination.

1869 Q. Now in the course of the analyses you made, you used a great many reagents?

A. Yes sir.

Q. Now did you investigate to determine the purity of the reagents that you used?

A. We did; we examined the purity of those reagents.

Q. What did you find with reference to them? Were they chemically in proper condition?

A. We found that those reagents, like the silver nitrate and the ammonium chloride, were chemically pure. We only used chemically pure reagents. In any case where it was not necessary to have chemically pure reagents we used the commercial articles. We took all the usual precautions that are outlined for such work in the standard reference books.

Q. Who is the leading manufacturer of what is regarded as absolutely pure chemical reagents?

A. Which reagents do you mean?

Q. Well, the chemicals used in the preparation of these analyses?

A. Well, we used the Kohlbaum reagents, for the organic chemicals like sulphanalic acid, and the alpha naphthylamine. We had the standard reagents from C. A. Kohlbaum, Germany, and we used pure chemicals for all of our work, as pure as we could get, and then we tested the purity.

Q. Now did you personally examine the condition from 1870 time to time of the apparatus that you used, the distillation apparatus with other things, in the laboratory?

A. Yes, I had supervision of the whole work, and I checked up the standard solutions used myself, and I made all the calculations. The notes furnished me by the assistants were not expressed in parts per million; they were expressed in so many cubic centimeters of water, standard solutions, and I made all calculations myself.

Q. Yes, but your apparatus there, did you keep them in proper cleanly condition from day to day?

A. Yes sir, certainly.

Q. Did you have a set of rules for your men to work by?

A. I did.

Q. Did you see that they were followed?

A. I did.

Q. If they were not followed, was the work rejected?

A. It was.

RE-CROSS-EXAMINATION, By Judge Springer.

Q. You stated in answer to a question put by General Crow, that before using the water furnished to the people of St. Louis through your waterworks, that you caused it to be filtered and boiled?

A. At my house, yes sir.

Q. At your house?

1871 A. Yes sir. I sometimes drink water when it has been run through a Pasteur filter. In the University we have a Pasteur filter, and that water has not been boiled, but it has been filtered very carefully.

Q. How much of the impurities would the Pasteur filter remove from the river water without boiling?

A. It would take out the larger proportion of the bacteria I believe.

Q. What would you say as to the waters in all the navigable rivers in the United States so far as their potable character was concerned?

A. Well, that is a very broad question and one that I am scarcely—

Q. Are there any waters in the navigable rivers of the United States that you would recommend people to use without being filtered and boiled, for drinking purposes?

A. Well, I imagine there are some rivers. The Upper Missouri is probably in a very good state, and it is navigable, I believe for many thousand miles. I believe the Missouri above Kansas City and St. Joseph, is a very fair stream and that it could be used as a potable water.

Q. Without filtration or without boiling, for drinking purposes?

A. I think so, I think above the larger towns it would be
1872 in good sanitary condition.

Q. Below Sioux City, Iowa on the Missouri river, and below St. Paul and Minneapolis on the Mississippi river, and below Pittsburg in the Ohio river, and below St. Louis on the Mississippi river, would you regard any of these waters as suitable for the best of purposes without some kind of treatment?

A. I think that all waters of our rivers ought to be filtered.

Q. Ought to be filtered?

A. Yes sir.

Q. Then there is danger of contamination from any of them unless they are filtered?

A. Yes sir. EDWARD H. KEISER.

1873 DR. WILLIAM C. TEICHMANN,

Resumed the stand for further direct examination by Attorney-General Crow, and testified as follows:

Q. Dr. Teichmann, please state your name, residence and occupation?

A. William C. Teichmann.

Q. What is your age?

A. Forty-three.

Q. Residence and occupation?

A. I live at 3624 Shaw Avenue, St. Louis.

Q. You were raised here in St. Louis?

A. Yes sir.

Q. Educated abroad and in this country?

A. Yes, partly in St. Louis and partly abroad.

Q. Just state your educational training, where you received it and what it has been?

A. I originally attended the Academic Department of the Washington University, and continued my education in the Polytechinc College at Brunswick.

Q. Whereabouts is Brunswick?

A. Brunswick, Germany, where I studied chemistry.

Q. How long did you study chemistry there?

A. For four years.

1874 Q. Then where did you go?

A. Then I studied chemistry in the University of Berlin, for a period of two years, particularly under Professor Tiemann, author of a well known book on water analysis, and considered in Europe as an authority upon the question of water.

Q. Well then where did you go to?

A. Then I studied a half year, or rather one semester as they call it, in Germany, in the University of Leipsic, and three and one-half years in the University of Munich, Germany. I graduated as a Ph. D. from the University of Munich, in 1885.

Q. Then what did you do?

A. I returned to this country at that time and for a number of years I was occupied with literary pursuits, and in 1890, I became private assistant to Professor Charles O. Curtman, who was Professor of Chemistry in the Missouri Medical College, of St. Louis, which college has subsequently been united with the Washington University.

Q. Then where was your next position?

A. And I was private assistant from 1890, until 1896, for Professor Curtman, and from 1891 until 1896, I was Assistant Instructor of Chemistry in the Missouri Medical College, assisting the professor of chemistry, Dr. Curtmann.

Q. Well, did you occupy any official position during this 1875 time?

A. Yes sir, in the year 1893, I was appointed City Chemist of St. Louis.

Q. Do you now hold that position?

A. Yes sir.

Q. And how many years did you put in on the exclusive study of chemistry and the allied subjects that were necessary to be understood to complete a practical chemical education?

A. Well, practically since the year 1875, when I entered college at Brunswick.

Q. Up to 1885?

A. Yes sir, ten years abroad.

Q. And then six years that you stayed abroad, in Germany?

A. No sir, I say—

Q. I say, six years of the ten years you had in Germany?

A. No, I was ten years abroad, I say, from 1875 until 1885.

Q. Now as a chemist, you have had occasion to analyze water and all classes and kinds of materials and substances, solid and liquid?

A. Yes sir.

Q. What class of work are you called upon to do in your position as City Chemist?

A. Well, the most important work and the largest part of the work consists of water analyses.

1876 Q. Well, what water is it you are called upon to analyze?

A. Well water, cistern water and river water, and water furnished by the City water supply.

Q. Is your office connected with the health department of this city?

A. Yes sir.

Q. Who is at the head of the Health Department?

A. Dr. Max C. Starkloff.

Q. Now what various branches of that department are there besides your own?

A. Well, the department is divided into sub-departments, and divisions.

Q. What are they?

A. Well, various city institutions are under the direct control of the Health Commissioner, and the Board of Health, also the Sanitary division, and the chemical division and the bacteriological division.

Q. Well now, who constitutes the Board of Health?

A. Six—the Mayor, President of the City Council, the Health Commissioner, one Police Commissioner, appointed by the Mayor, and two members of the medical fraternity of St. Louis who are appointed by the Mayor for a period of four years.

Q. Now who is the City Bacteriologist?

A. Mr. Charles A. Snodgrass.

1877 Q. Does he have any employes under him?

A. I think he has, yes sir.

Q. How many?

A. Well, to my knowledge he has a janitor and a stenographer.

Q. Now who is the Health Officer?

A. Do you mean the Health Commissioner?

Q. Health Commissioner?

A. Dr. Max C. Starkloff.

Q. No I mean the Sanitary officer.

A. The assistant health commissioner, who represents the Health Commissioner during his absence, is also chief Sanitary Officer.

Q. And who is he?

A. Mr. Charles W. Francis.

Q. Now how many people does he have under him?

A. Well, that I can't tell; that varies according to the appropriations and the requirements of the department.

Q. Well, how many—a great many, doesn't he?

A. Oh yes, it may vary from 25 to 50.

Q. Now what branch of the Health business does he look after?

A. Well, he represents the Health Commissioner and looks after the general health and the sanitary conditions of the community.

Q. Well, he enforces inspection of those too?

A. Yes sir.

Q. Now how many men have you got in your department?

1878 A. That varies according to the requirements. My regular employes consist of—well, there is myself, the City Chemist, the Assistant City Chemist, there is a clerk and helper at the distillation table, and the janitor.

Q. Well how many does that make?

A. Four. Four men constitute the regular force, but the milk inspection having been added to the City Chemist's office in August of last year, gives us five additional employes, two analytical chemists, two inspectors and a clerk.

Q. Now where is your office located?

A. It is located in the old City Hall of this city.

Q. In what part of the city?

A. In the eastern part of the city.

Q. Well, what street?

A. 11th and Chestnut.

Q. Have you a laboratory there?

A. Yes sir.

Q. Now you are acquainted as a chemist, with what it takes to equip a laboratory for practical chemical work?

A. Yes sir.

Q. Well, have you got the necessary equipment there to carry on practical water analyses, and such other analyses of substances as may be submitted to you?

A. Yes sir.

Q. How many rooms have you?

1879 A. I have six rooms.

Q. Well, did you make the analyses for the city of the water—City and State,—of the waters of the Mississippi, the Missouri and the Illinois Rivers, and the Drainage Canal and Lake Michigan?

A. Yes sir. I made them or superintended their analysis.

Q. Beginning in the year 1899, on up to December last year?

A. Yes sir, during that period beginning with August, 1899, up to the present time, I made water analyses of samples taken from these various places you have mentioned.

Q. Now, prior to your beginning that work, what experience had you had as a water analyst?

A. I had repeatedly analyzed samples of water from the river and I had made quite a number of analyses from the tap in the City Chemist's office, at that time, and I analyzed a large number of samples of water taken from wells and cisterns in St. Louis.

Q. Well, during the ten years, or the seven years that you have been City Chemist, prior to the period I have mentioned, in 1899, was it a part of your duty to make water analyses?

A. Yes sir.

Q. You have been making them how often, monthly or yearly?

A. Well, that depended upon the respective orders from the Board of Health, or from the Health Commissioner, and according to my own judgment, whenever I thought that the
1880 city water supply necessitated analysis of the water to find out its character.

Q. I believe you said that at some place in Germany, at Brunswick or Berlin, you took a special course of study under Tiemann, who is a water analyst, or water chemist?

A. I didn't exactly take a special course, but I worked under him. He was my instructor at that time.

Q. Well, did you make any analyses of water there?

A. Yes sir.

Q. How long a period did that cover?

A. While analytically working under him I performed them for a period of about one year.

Q. Well, at any other points did you perform any practical analytical work of analyses of water?

A. Yes sir.

Q. Where and when?

A. In Brunswick.

Q. Brunswick, Germany?

A. Yes sir.

Q. How long did you continue that work?

A. Well those analyses were simply made, as they were required in the course of instruction. That is part of the course to be followed.

Q. Well at any other points besides Brunswick, and this instruction under Tiemann, in which you made practical analyses of water during your student days?

1881 A. I didn't make any more water analyses after I left the University of Berlin until I returned to St. Louis.

Q. Well, as instructor or assistant instructor to Professor Curtman, were you called upon to make any water analyses?

A. Yes sir. It was part of the instruction of the laboratory but I performed more analyses in his private laboratory, private analyses that he was requested to make.

Q. Well, how often would you make these practical tests of water?

A. Well that I could not say exactly, because just from time to time as samples of water came in for analysis, they were analyzed.

Q. Well in the course of your experience prior to the investigation of these waters I have mentioned, beginning in 1899, have you had any practical experience in analyzing waters to determine their wholesomeness and potability for primary and domestic use?

A. Yes sir.

Q. What experience have you had?

A. Well, the experience that I acquired during the—principally as the private assistant to Professor Curtman, and as City Chemist, beginning with May, 1893.

Q. Did you have charge of the examination of these waters
of the Illinois, the Missouri and the Mississippi Rivers,
1882 and the Drainage Canal and Lake Michigan?

A. Yes sir.

Q. Were all the water analyses made under your supervision?

A. Yes sir.

Q. Did you procure Professor Keiser to do the work which he did?

A. I suggested to the City Authorities that Professor Keiser be engaged for duplicate work.

Q. Well, the work which he did, did it correspond with the work that you did, in quantity, in other words did you do duplicate work, the same as he did?

A. Yes sir.

Q. Worked on the same samples?

A. Yes I performed duplicate, or rather I superintended the analyses of duplicate samples, with the samples that Professor Keiser received in my laboratory.

Q. Now who provided the method that should be followed in the collection of these samples; who laid down those rules?

A. Well, I carefully prepared these rules, and submitted them to the Health Commissioner, and I discussed some of the rules with Professor Keiser, and the rules were practically the embodiment of our joint ideas.

Q. Did you have charge of the men that collected the water samples for the bacteriologist also?

1883 A. For part of the investigation, yes.

Q. What portion?

A. Well, all samples that were collected and sent to St. Louis or delivered at St. Louis by the collectors; they usually came to the City Chemist's office first and were then sent to the laboratory of Dr. Ravold, who had charge of the bacteriological work, but there have been a great many samples collected at various stations—the so-called bacteriological stations along the route between Chicago and St. Louis, and those collections were made under the direction and responsibility of the respective assistants of Dr. Ravold that had charge of those stations.

Q. Now did you follow any method or system, that is well known and recognized among water chemists and water analysts, in the rules laid down by you for the collecting of these samples of water?

A. Yes sir.

Q. What particular system of rules did you follow?

A. I studied the rules observed by leading water analysts of the country, and also some of the analysts of Germany, as recommended in standard books, and then considered the local conditions and tried to adapt the rules as much as possible to a most accurate result in the collection of samples.

Q. Well, you organized the inspection force then that went to work upon these samples of water?

1884 A. Yes sir.

Q. Now just tell me how you organized them, how many men you had and how you divided the duties?

A. I would have to refer to my report.

I mentioned in my previous testimony the various periods of investigation and the number of men employed, and the system of collection differed somewhat during those periods; that is, the investigation when it started, was not conducted on the comprehensive scale that it finally assumed, or rather assumed after the Drainage Canal was opened.

Q. Well, I am dealing now only with the question of the collection of the samples?

A. Yes sir.

Q. Not the method of the work pursued in the laboratory. Now just go ahead and give me the method which you followed in organizing the bureau for the collection of those samples?

A. During the first period of investigation, beginning August 23rd, and ending January 22nd, the samples were partly collected by myself, on occasions of personal visits to the various points of collection between St. Louis, and the mouth of the River and the Mississippi River a few miles above the mouth of the Illinois. They were partly collected by special collectors engaged for that purpose, and my janitor. 1885

Q. Well, do you know the names of those men that you engaged?

A. Yes sir. The force employed in this work consisted during this period, of myself and the Assistant City Chemist, Mr. Thomas A. Buckland, collector of samples and helper at distillation table, Henry R. Taylor, Sr.

Assistant collector of samples and helper at distillation table, Henry R. Taylor, Jr.

Assistant collector of samples and helper at distillation table, Herman Ungar.

Then during this period a number of trips were made by the Harbor boat at St. Louis, and on several occasions a private boat was engaged for these trips. The trips were made up to the mouth of the Illinois River and samples were collected as we proceeded up the river from the Intake to the mouth of the Illinois and returning, and also samples were collected from the mouth of the Illinois. On such occasions these samples were partly collected by myself, or by one of the assistants whom I have mentioned.

Q. Now how far up the Illinois River and the Mississippi River did those examinations extend?

A. They extended up the Mississippi River to a point five miles above the mouth of the Illinois River, and up the Illinois River to a point five miles above Grafton.

1886 Q. Did they extend into the canal?

A. No sir, that is investigations prior to the opening of the canal.

Q. Did they extend into the Chicago River?

A. No sir.

Q. Did they extend into Lake Michigan?

A. No sir.

Q. Now what means did you provide for getting these samples to St. Louis and into your laboratory?

A. These samples when I collected them, I usually had my janitor with me, who carried them after I had sealed them—carried them to the City Chemist's office, or when they were collected by anybody else, either from the harbor boat or from the private boat engaged for a few times, or when they were collected by special men sent up to the mouth of the Illinois river, on a few occasions, they were always brought by these people to the City Chemist's office,—that is, all samples in a sealed condition, because immediately when they were collected they were sealed.

Q. When they were received at the City Chemist's office was there any preparation there for the storage of them?

A. Yes sir.

Q. Or were they analyzed immediately?

A. They were usually analyzed immediately, if arriving during day time or not later than eight or nine o'clock in 1887 evening, when we would return from the harbor boat; sometimes we wouldn't get back until ten o'clock at night? Then of course the samples could not be analyzed right away, but when we got back to the city, if the samples reached the laboratory before eight o'clock, we would immediately proceed with the analysis for ammonia,—or the distillation process which I shall describe later on, and for nitrites.

Q. Well, was there any preparation made for the observation of the water, the temperature of it, after its being taken from the river prior to its being received into the laboratory?

A. The temperature of the water and the temperature of the air was always taken and recorded at the time of collection.

Q. Yes, but the water, was there any preparation made to preserve the temperature of the water either above or below what it was when taken from the river, at the time it was taken?

A. A part of the samples,—the earlier samples, they were not packed in ice at the time of their collection, and were brought to the laboratory in that form, without having been packed in ice, but that was only for a short time. For a few weeks, and then I had little tin boxes prepared where ice was contained in one section of the box, and the bottles placed in the other side so as to have a kind of an improvised refrigerator, and
1888 the samples were then brought to the laboratory, and all
samples, when they were brought to the laboratory were always put in an ice chest so as to keep them at a low temperature.

Q. Well, did you have any rules for these water collectors to follow specifically, when collecting water, as to where they should take it from or on the surface, at the bottom of the river in the middle of the river, or at the shore line?

A. The very first samples, for the first few weeks were taken in demijohns, and we would lie down in the boat and take the samples from a little skiff—rather—we would lie down in the skiff and reach down with our arms, reach down the demijohn as far below the surface of the water as we could possibly, so as to get the water at a depth of about an arm's length; but after a few weeks we had an apparatus constructed which I exhibited in my previous testimony.

Q. Well, Complainant's Exhibit Number 15. Just describe it that way?

A. Yes sir.

Q. Just describe it that way then?

A. Complainant's Exhibit Number 15. The collectors were instructed, and whenever I would collect the samples myself, the machines were extended into the water down to the handle, down as far as we could get it, so as to get it about three or four feet if possible—

1889 Q. Below what?

A. Below the surface.

Q. Now whereabouts, with reference to the shoreline of the river were these samples taken during this period from August 1899 to January 22nd, 1900?

A. Well, between the mouth of the Missouri and the Intake, these samples from the shores were taken from the Missouri shore and from the Illinois shore.

Q. No, you don't understand me, doctor. I guess you are confused a little bit there by that talk there, and you didn't notice.

I say whereabouts were these samples taken from, with reference to the location of the boat to the shore line; was it on the shore or off the shore, and if so, how far?

A. Well, we would get into a little skiff and we would watch the currents, and if we wanted a sample from either shore, we would endeavor—or the collector, if I would not be there,—would endeavor to get the samples—to get samples from those currents which hugged the shore. There was no measurement or anything; it was simply to get the water that runs along the shore line.

Q. Were any of the samples taken from mid-stream or out in the channel?

A. Yes sir.

1890 Q. Well, at what points were they taken, out in the mid-stream?

A. Well, that would be very hard to describe.

Q. Well, haven't you a record of that?

A. Well, there were no measurements from the shore, so that we could indicate how far from the shore it was taken; it was generally individual judgment. If we wanted to get a sample from mid-stream we would see where the current was and right from the middle of the current we would take the sample.

Q. Well, have you got any official record of this work?

A. Well, later on we took what we call cross-sections.

Q. What do you mean by later on? Do you mean in 1901, or do you mean in the fall of 1899?

A. In 1901, in the fall, we took what is called cross-sections, and of course we didn't know what the distances from the shore were, of those cross sections. Twelve samples were taken right across the river in a line—

Q. Have you got a record of those cross-sections?

A. Yes, but that is work that was performed in subsequent periods, and that don't belong to this period. Work was done in this period—

Q. I am asking you if you have got any record whatever of the work that you did from August, 1899 to January 22nd, 1900?

A. Yes sir.

1891 Q. Now what shape is that record in?

A. Well, the record of the collections is first recorded on the tags that were presented here.

Q. Now those tags and that record shows where the water was collected, don't they?

A. Yes sir.

Q. Then you were mistaken a while ago when you said that you had no record of the place where those samples were collected, weren't you?

A. Well, I undestood it this way, that you wanted exactly the location recorded, where those samples were taken. That of course, would be impossible. I misunderstood you.

Q. Now what does the record on the tag indicate?

A. The record on the tag on the samples collected from the Misouri shore, the sample collected from the Illinois shore—

Q. Well at any particular point?

A. Yes sir.

Q. Well, at Hartford, Alton or Chain of Rocks?

A. Well, it would say so—chain of rocks.

Q. But the record of the location in the particular part of the stream you haven't got?

A. No sir.

Q. But you say that it was taken off shore?

A. Yes sir.

1892 Q. Now how about the Illinois River; have you got any record of the samples you took up the Illinois River from August, 1899 to the 22nd of January, 1900?

A. Yes, there were 19 samples taken from the Illinois river at points one, two, three and five miles above Grafton.

Q. Now where were they taken with reference to the shore line of the Illinois River?

A. They were taken from the current.

Q. Well, when you use the term "current" do you mean the channel of the river?

A. Channel of the river, yes sir.

Q. Now what was the stages of the Mississippi, the Missouri and the Illinois Rivers from August, 1899 to January 22nd, 1900?

A. I have got the record of those stages—

Q. Yes, but generally speaking, were the rivers low or high or at mean stages of water?

A. The Illinois River at that time was comparatively low; I say comparatively, because it has been lower, at other times.

Q. How about the Missouri and the Mississippi?

A. The rivers were all comparatively low at that time. I can't tell exactly because I haven't got the data here just now.

Q. Now did you take any samples up the Missouri River?

1893 A. I took them at the mouth of the Missouri, but sufficiently far enough up into the river so as to get Missouri River water only and no back water from the Mississippi.

Q. Well, how far up the Missouri River did you go?

A. Probably a mile.

Q. Above the point of confluence of the two streams?

A. Yes sir.

Q. How many samples did you take?

A. Ten samples.

WILLIAM C. TEICHMANN.

ADJOURNED until following morning, Tuesday, March 17th, 1903, at ten o'clock A. M.

1894 Southern Hotel, St. Louis, Mo. 10:00 a. m., Tuesday, March 17, 1903.

Present, the Commissioner and same Counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN resumed the stand for further direct examination, by General Crow, and testified as follows:

Q. Now, go ahead and tell what you did about investigating these waters in your own way?

A. The other samples collected from points between the mouth of the Illinois and the Intake tower in the Mississippi river during that period were from Madison Landing between the Chain of Rocks and the mouth of the Missouri River on the Missouri shore, three samples.

Then Madison Landing, Illinois shore seven samples.

Going farther up the Mississippi River between the mouth of the Missouri and the mouth of the Illinois there were thirteen samples collected at points between Alton and the mouth of the Missouri River.

Six samples between Alton and Portage—Portage is about half way between Alton and Grafton,

1895 Near Clifton Terrace six samples.

Then Elsa, near Piasa Bluffs, between Portage and Grafton, half way between Portage and Grafton, five samples.

Do you want anything about the method of collecting these samples and their treatment at the laboratory?

Q. Yes, put in there whatever you want about that?

A. All the samples collected during this period were properly sealed as heretofore described and opened at the laboratory for analysis by myself and my assistant, Mr. Thomas A. Buckland.

Do you want to have a general discussion of the period prior to the opening of the Drainage Canal now in connection with the analytical investigation?

Q. Well, just go ahead and describe what you have done there in investigating these waters?

A. Do you want to ask that in the line of regular questions or do you want me to give a general description of it?

Q. Go ahead and state what you did and we will get through quicker that way.

A. I mean do you want to have a description of the Illinois River water shed and a discussion of the volume of flow and its various tributaries?

Q. I don't think that is necessary, but you can put it in if you want to.

A. I will leave it to your judgment.

1896 Q. I would suggest to you just to answer my question.

A. Your question is so general I don't know what part of the investigation and what part of the results you want to have discussed first.

Q. I would start at the beginning if I were you and go right through. I think you can do that better than if I ask you detailed questions.

A. Well, in order to give proper weight to the sources of pollution which affect the sanitary character of the Illinois River we will have to consider some figures from responsible authorities on the effect of dilution from the Illinois and Michigan Canal and the tributaries.

Since it is of the greatest importance to find out the stages of the river during the periods of drouth we will look for the low water stages of the Illinois River water shed. Perhaps the lowest low water stage on record is that presented and discussed from the United States Government data by Lyman E. Cooley in a report published in 1890, entitled "Lakes and Gulf Water Ways, as related to the Chicago Sanitary Problem."

Mr. Cooley divides the Illinois River water shed into two divisions, Lake Joliet to Utica, and Utica to the mouth. Now, he gives the low water volume from Lake Joliet to Utica as follows: "The Des Plaines has been measured twice for low
water, in 1887 giving 256 feet per minute and in 1879
1897 339 feet per minute, I think between Riverside and Lock-
port. The extremely low water at Wilmington, on the
Kankakee river for 12 years, from 1871 to 1883 was 25,200 feet per minute. A measurement made September 9th, 1867, at the mouth of the Kankakee in connection with General Wilson's United States survey gave 27,377 cubic feet per minute. The water was said to be lower in 1867 than for the previous twelve years. The quantity in the Fox River September 17, 1867 was 31,539 feet per minute. The Mazon was practically dry. From May 13th to the 28th, 1887, at Morris the water was then two or three inches within the lowest since 1856, and it is doubtful if the amount was to exceed 15,000 or 20,000 cubic feet per minute, or 250 to 350 feet per second. At least 60 per cent. of the whole water volume passing Morris in 1887 came from Lake Michigan by the Illinois and Michigan Canal and probably one-half of the volume in ordinary low water years, comes from this source. A measurement has been made at La Salle by the Canal

authorities before the canal was deepened, of 37,900 cubic feet per minute, and doubtless Lake Michigan water has represented one-half of the volume passing in some recent low water periods. Now, this is a quotation from Cooley's work and I will add also a quotation on the low water volume from Utica to the mouth.

MR. JOHNS: The defendant, the State of Illinois, ob-
1898 jects to the reading into the record reports from books of whatever character or description, for the reason that if the evidence is competent the books themselves are the best evidence.

A. Well, I can present this report as it was published by Lyman E. Cooley at that time and I can refer to the quotations as coming directly from this scientific work.

MR. JOHNS: There is no question about the correctness of the work. It is simply incompetent as evidence.

MR. TODD: And the Sanitary District wishes to object on the ground of its incompetency.

THE WITNESS: What is your pleasure, Mr. Crow?

GENERAL CROW: Go ahead.

THE COMMISSIONER: You may go ahead and make your statement.

A. The low water volume from Utica to the mouth. "The low water volume of the Illinois after the ponds, lakes, sloughs and marshes have been drained out as they are in long seasons of drouth, shrinks to very small proportions, proof conclusive of the lack of permeability of the subsoil and underlying lakes of the Illinois River basin. In 1888, the water running over Henry Dam was less than 500 cubic feet per second for nine days, and at Copperas Creek, for 20 days. But the water at Copperas Creek was at or below the same level in 1887 for 117 days and in 1886, 18 days, and in 1879 for 44 days, and at Henry in 1877 for 30 days, and in 1875 for 47 days and in 1871 ap-
parently for a longer period. The volume in 1888 was less
1899 than that sent through the canal at Chicago for the same
period, about 700 cubic feet per second, and lake water from 300 cubic feet upward has been going to the valley since July, 1871. How much leakage there might have been through the dams at this time is unknown. In 1867 or earlier the measurement was made at La Salle of 633 cubic feet per second and

in 1879 in the lower section of the river 1566 cubic feet, and in 1887, 1685 cubic feet. Part of the water in the last two measurements is chargeable to Lake Michigan. It is probable that since the Bridgeport pumps were erected in 1883 over half of the minimum discharge above Havanna has come from Lake Michigan, and one-third of the minimum below the Sangamon. For the purposes of calculation the normal low water volume is taken at 600 cubic feet per second for the upper section of the river, (and this agrees with the figures I find in the report published by the Illinois State Board of Health and embodying a special report on this question by Civil Engineer Harmon). As I said I quote here from Cooley for the purpose of calculation the normal low water volume is taken at 600 cubic feet per second for the upper section of the river and of 1200 cubic feet per second for the lower section. If Chicago were to pump 2000 cubic feet pending the completion of the ship canal it would mean a great deal to the lower Illinois."

Now, I wish to state that it will be seen in the year 1887,
1900 60 per cent of the cubic feet per minute at Morris was
due to the flow of the Illinois and Michigan Canal, or in other words, the natural flow in the Illinois above that point was only 8000 cubic feet per minute, or 134 cubic feet per second. From Lyman Cooley's remark we may assume for the purposes of calculation, that the natural low water volume independent of Chicago sewage, above Havana is 300 cubic feet per second and below this point is 800 cubic feet per second. Now, this is the condition prior to the opening of the Chicago Drainage Canal. From those figures I have calculated the following ratio of dilution of Chicago sewage in the Illinois River prior to the opening of the Drainage Canal: Upper Illinois volume of flow 600 cubic feet per second, as established by Lyman E. Cooley and Civil Engineer Harmon.

Sewage of Chicago, 400 cubic feet per second, ratio of dilution 1:0.5.

Lower Illinois: Volume of flow: 1200 cubic feet per second—that is the upper district runs to Utica and the lower district from Utica to the mouth. That is, the lower Illinois had a volume of flow 1200 cubic feet per second and sewage of Chicago 400 cubic feet per second, making the ratio of dilution one to two. I deduct the sewage from the water.

Now for instance, 600 cubic feet of water I have there and I have 400 cubic feet of sewage, that leaves 200, 200 to 1901 400 equals 0.5, as the ratio of dilution, and in the same way we would refer to the 1200 cubic feet of volume per second in the lower Illinois and sewage 400. Deduct that 400 from the 1200 and it leaves 800, and 400 is to 800 as is one to two.

I will later on compare this low water dilution with the amount of water coming from the Chicago Drainage Canal added to it, and will then show a different ratio of dilution after the Drainage Canal has been opened.

Now, the amount of sewage from Chicago was obtained by taking it equal to the water supply which is 42,000,000 cubic feet per day. This is a rational assumption and it is often used in sewage computation. As Professor E. O. Jordan, in an article, written for the "Journal of Experimental Medicine" in 1900, states, that only four-fifths of Chicago sewage has been discharged by the Illinois & Michigan Canal, we have thus deduced 400 cubic feet per second as the amount of sewage discharged there prior to the opening of the main Drainage Canal.

Of course, these dilutions are given only to show just what proportion of the Illinois River is made up as the diluted sewage of Chicago and the purification of this sewage must be taken seriously into account before arriving at definite conclusions.

JUDGE SPRINGER: Will you repeat that again?

1902 A. Professor Jordan advances it in this article written for the Journal of Experimental Medicine, that four-fifths of the Chicago sewage went into the Illinois & Michigan Canal. That was prior to the opening of the Chicago Drainage Canal, and with the proper deductions there we got 400 cubic feet per second of the amount of sewage discharged therefrom into the Desplaines River or into the Illinois River prior to the opening of the main drainage canal. Mr. Crow, do you want the drainage areas?

Q. MR. CROW: Just go ahead and give your methods of making these analyses.

A. The population draining into the rivers?

Q. No that is not necessary.

A. It is an important statement made from data obtained from Lyman E. Cooley's report, as to what the amount of drainage area is.

Q. Just go ahead and give your methods of making these analyses.

A. In selecting the methods for analyses I studied the methods applied by Professor Thomas M. Drown in his investigation of the Massachusetts Water supplies. An investigation conducted on a very elaborate scale in the years 1887 and 1888 and the results of which were embodied in a report that is today considered a standard work on methods of analyses.
1903 I also considered the methods recommended by prominent authorities on water analysis such as Tieman of Berlin in his work "Unter-Suchung des Wassers." This work is really an enlargement of a previous work written by Kubel, the inventory of the Permaganate method of the determination of organic matter in water.

Furthermore, I considered such works as Mason's "Examination of Waters" and Leffman and Bean's Examinations of Waters, and a few other works of lesser importance.

For the determination of ammonias I found a process recommended by Mason and Leffman based upon a recommendation by the American Association for the Advancement of Science. This method varied somewhat from the ordinary method, what we call the Wanklyn and Chapman method for the determination of ammonias in so far as the total ammonia is estimated first by distillation through an ordinary condenser; the free ammonia is determined in separate samples and the free ammonia finally deducted from the total ammonia.

The original distillation method implies as it was designed by Wanklyn originally and modified by Chapman and Miller. I say the original Wanklyn and Chapman method implies a distillation of the free ammonia from one sample and after the free ammonia has been distilled over a Permaganate solution is added to the residue in the flask and distilled over.
1904 This Permaganate will liberate what is called the albuminoid ammonia.

Later on during the investigation I abandoned the so-called Mason method of distillation of the ammonia and returned to the Wanklyn and Chapman method, because I found the Mason method cumbersome and time robbing and came to the conclusion that results just as accurate could be obtained by the elder method.

The apparatus used for the determination of ammonia consists of round bottomed flasks of about one litre capacity, which were obtained from Schott & Genossen in Jena, Germany made of the so-called Jena glass, which glass has the advantage that it can stand any temperature of heat required for the distillation and that it will not give off any alkali which may happen to flasks of quality not as good as these of Schott & Genossen. These flasks were connected with a large condenser of galvanized iron with ten inner condensing tubes of block tin. They were connected with the condensing tubes by means of rubber stoppers, which had been previously boiled for several hours, to remove any ammonia possibly connected with the rubber stoppers, or rather surrounding them. These flasks and the apparatus before they were used for the analysis in each instance, were first freed from possible ammonia that
1905 might have been there, by filling the flasks with about
two-thirds of ammonia free water. They were connected with condenser and the water was distilled off through the condenser, until the distillate gave no color with Nessler reagents, in other words we observed the precaution to clean out the flasks as well as the condenser tubes through which the steam passes and is condensed again by the water flowing through the apparatus and cooling off the steam so as to change it back to water. I say there was a guarantee of no ammonia being present in these tubes. Then when we were certain that the condenser was free from ammonia and the flasks free from ammonia, these flasks were used as follows:

If it was a sample of unfiltered water to be analyzed 500 cubic centimeters were measured into an accurately colibrated flask and poured into the distillation flask. Ten cubic centimeters of a sodium carbonate solution was added, the flask connected with the condenser and the distillation of the free ammonia begun. This distillate was collected in 50 cubic centimeters of so-called Nessler tubes. When five tubes had been distilled off the apparatus was disconnected and allowed to cool slightly.

Now, when we applied the Wanklyn and Chapman method
100 cubic centimeters of ammonia free water and 50
1906 cubic centimeters of alkaline potassium Permanganate
solution the nature of which I shall describe yet, were added. The flasks were reconnected and the distillation of the albuminoid ammonia proceeded with until five tubes had been collected. The distillation tubes having been completed a set of standards containing definite quantities of ammonium chloride solution was prepared as follows, and that was for comparative purposes:

Into a set of Nessler tubes was placed respectively, .1, .3, .5, .7, 1, 1.3, 1.5, 2, 2.5, 4, 6, 8, 10, 12, 15, 18 and 20 cubic centimeters of the standard solution containing .01 milligrams of ammonium chloride in each cubic centimeter. The tubes were filled to the 50 cubic centimeter mark with ammonia free water, then to each of the set of standards and the distillates from the samples one cubic centimeter of the Nessler solution, which is alkaline mercuric potassium iodide solution, was added and the tubes allowed to stand for 10 minutes when the comparison of the samples with the standards was made and the results recorded in a book.

Now, as regards the Mason method for the determination of albuminoid ammonia, six tubes of free ammonia were distilled from five hundred cubic centimeters of the sample of water.

Then, as I said before, a fresh portion of water was
1907 taken for the albuminoid ammonia determination or
rather the total ammonia determination; 50 cubic centimeters of the Permanganate solution added and nine tubes of the distillate collected. This represented the total ammonia present in the sample and the albuminoid ammonia was ascertained by a subtraction of the free ammonia from the total ammonia as found in the second sample.

In all ammonia distillations a period of ten minutes was allowed for the collection of each tube of the distillate and I wish to say that I had employes stationed at the condenser with a clock in front of them and carefully keeping the time of each distillate, in other words they had to be careful that the tubes did not fill sooner than ten minutes or later than ten minutes. Some authorities raise the point that there ought to be uniformity in the time these ammonias require as they come over the condenser and go into these tubes; that if these tubes fill too soon or if it takes too long a time to fill them, that the results in the end may not be accurate. The controversy upon this matter is still going on and I think has not been definitely settled yet. The American Public Health Association has appointed a committee to formulate standard methods of analysis and it is to be expected that within a year from now their report will be forthcoming and this matter will be definitely settled then. 1908

In the meantime, in order to have accurate results we were careful to have the ten minutes limit observed by those working at the distillation table and collecting the distillates.

The ammonia reagents used in the analyses of these samples were as follows: Standard ammonia chloride solution 3.82 grams of ammonia chloride were dissolved in enough ammonia free distilled water. When I say ammonia free distilled water I mean this water was tested before being used for this purpose to see whether it contained ammonia or not, and only absolutely ammonia free distilled water was used for making up this standard solution. The standard solution from this strong solution is made by diluting ten cubic centimeters to a litre with ammonia free water. One cubic centimeter of the standard solution contains, therefore, .01 milligram of nitrogen.

The Nessler solution which was used was made up as follows, 62.5 grams of potassium iodide were dissolved or rather mixed with 250 cubic centimeters of distilled water also absolutely chemically pure. Twenty cubic centimeters of this solution were reserved and added to the remainder or rather the remainder was added to a cold saturated solution of mercuric chloride until a slight permanent red precipitate appeared. 1909 This was dissolved with the reserved portion of the potassium iodide solution and to it cautiously was added the mercuric chloride solution until a slight permanent red precipitate again appeared. Then 150 grams of potassium hydrate dissolved in 250 cubic centimeters of chemically pure distilled water were added and the entire mixture allowed to stand over night, when on the following day it was ready for use.

The alkaline potassium Permanganate solution which was used for the liberation of the albuminoid ammonia was composed of eight grammes of potassium Permanganate and 200 grams of potassium hydrate and dissolved in 1250 cubic centimeters of distilled water and boiled down to one litre. The boiling in this instance was required for the purpose of removing possible ammonia in the mixture.

The sodium carbonate solution was composed of 60 grammes of anhydrous sodium carbonate dissolved in 1250 cubic centimeters of distilled water and boiled down to one litre.

I now come to the method for the determination of nitrogen in the form of nitrites. For this purpose I investigated a number of methods recommended by the various authors I have mentioned and I came to the conclusion that the method recommended by Prof. Drown, what we call the Gries-Warrington
method was the best.With this method recommended in
1910 Professor Drown's report to the Massachusetts State
Board of Health in the chapter entitled Examination of
Water Supplies 1890," on page 527.

I furthermore wish to state that a work has since been published, since we began these investigations, by Richards & Woodman, who belong to this Massachusetts School of chemists and were trained under Thomas M. Drown and who have published an excellent work on water analysis entitled "Air, Water and Food." That they also recommend this method on page 94.

Furthermore, William P. Mason, in his book on "Examination of Water" also recommends it on page 36. It is the method that is generally recognized now as the most reliable method for the determination of nitrites in water.

I also wish to state that Professor Arthur W. Palmer of the Illinois State University in a report entitled, "The University of Illinois Chemical Survey of the Water Supply of Illinois," recommends the same method on page 13, and so does Leffman on page 49 in his work, "The Examination of Water for Sanitary and Technical" Purposes.

The method is as follows and was applied in the manner I describe it here:

The sample of water is clarified and decolorized. About

1911 200 cubic centimeters is placed in a wide mouthed glass stopper bottle of about 250 cubic centimeter capicity, and from threeto six cubic centimeters of the so-called milk of aluminus aluminum hydrate suspended in water, is added. It is thoroughly shaken and allowed to stand for about ten minutes. The sample is then rapidly filtered through an 18 1-2 cubic centimeter filter, previously washed with nitrate free water. The standards for comparison are as follows: In Nessler tubes of 100 cubic centimeter capacity are placed respectively, one cubic centimeter, three cubic centimeters, five cubic centimeters, seven cubic centimeters, ten cubic centimeters, twelve cubic centimeters, fifteen cubic centimeters, twenty cubic centimeters, of the standard nitrite solution containing sodium nitrite representing in quanity .0001 milligram of nitrogen per cubic centimeter. The tube is then filled up to the 100 cubic centimeter mark with nitrite free water. 100 cubic centimeters of a filtered sample of water is placed in a Nessler tube, to each tube of the set of standards and to the sample of water to be analyzed are added three drops of a one-half solution of hydro-chloric acid and two cubic centimeters each of a solution of sulphanilic acid and alpha naphthylamine. The solutions are then thoroughly mixed and after standing twenty minutes the pink shade of the samples is compared if it contains nitrites it will produce
1912 a pink shade, it is compared with that of the standards
above mentioned which contain relative quantities of the nitrites used for the reagent for comparative purposes and the result is noted. When a sample contains more than the amount of nitrites represented by 20 cubic centimeters of a standard solution, it is diluted with nitrite free water, that is water that had been previously examined to see whether it was free from nitrites. Usually in the proportion of 1 to 10. After the analysis of a few samples from each point of collection the necessary amount of dilution to bring each sample within the 20 cubic centimeter limit was readily anticipated. The milk of alumina or albuminum hydrate used in the clarification of the sample of water was made by precipitating the aluminum hydrate from a solution of aluminum sulphate by means of ammonium hydrate or sodium carbonate, the aluminum hydrate being washed by repeated decantations with nitrite free water

until no nitrites remained, if they were present. The standard nitrite solution, the pure silver nitrite used in making the solution is prepared by the double decomposition of silver nitrate and potassium nitrite and repeated crystallizátions. 1.1 grams of this silver nitrite are dissolved in nitrite free water, the silver completely precipitated by the addition of a solution of chlorine chloride and the solution made up to one litre. It is then kept in an amber bottle away from the light, in
1913 the dark.

This solution is diluted one cubic centimeter to one litre. One cubic centimeter then equalling .0001 milligrams of nitrogen.

The hydrochloric acid used was diluted one part of acid and two parts of nitrite free water. Sulphanilic acid was composed of 8 grams of sulphanilic acid dissolved in one litre of water. It is also kept in an amber bottle away from the light. The alpha napthalyne solution was prepared in the following way: 8 grams of napthalyne was dissolved in 992 cubic centimeters of water and 8 cubic centimeters of hydrochloric acid added. It was kept in an amber bottle and away from the light. The distilled water was river water redistilled continously with sulphuric acid until we had received absolutely pure water.

We now come to the nitrates.

Q. You did that in the ordinary method. You find the nitrates in the ordinary approved method, didn't you?

A. Yes, I use what you call the aluminum Poil method, also recommended by Professor Drown and other leading authorities. Do you think I had better read it?

Q. It is the same as with all the other constituent elements that you found in this water were found? You did it according to approved methods of analyses, didn't you?

1914 A. Yes sir.

Q. I wouldn't put in any more of that?

A. Do you want to have the chlorines in?

Q. There is no use in going into these methods in detail, just go ahead now and begin and give the results of your examinations?

A. I might state that I used the silver nitrate method for the determination of chlorine, also recommended by the various authorities whom I quoted. Shall I now proceed with the description of the conditions in the Illinois River prior to the opening of the Drainage Canal as far as my investigation is concerned as well as the investigation of other scientists in 1899?

Q. Yes, and make it as brief as you can?

A. As I stated on a previous occasion when I testified here our means or resources for the examination of the waters prior to the opening of the Drainage Canal were somewhat limited, and that we confined our collection of samples, as far as the Illinois River was concerned, to the mouth of the Illinois River. Therefore, I have no data for my own analytical work of the condition of the Illinois River in 1899, a point five miles above Grafton, but there are valuable contributions of analytical invegetations of the Illinois River that can give us a fair
1915 idea of the condition of that river in the year 1899, and
I have consulted the following reports: Long "Water Supplies of Illinois," that is a report published by John H. Rauch, M. D. Part 1 of this report, which was published in 1889 by the Illinois State Board of Health, and contains a contribution from Professor John H. Long of Chicago, entitled, "Chemical Investigations of the Water Supplies of Illinois."

Then, there is a contribution on this subject published by Professor Palmer, Professor of Chemistry in the University at Illinois, entitled Chemical Survey of the Water Supplies of Illinois.

Then, the Illinois State Board of Health report, "so-called advance notes of the sanitary investigation of the Illinois river and its tributaries," by Professor John H. Long, published in 1900.

Then an article written for the Journal of Experimental Medicine, Volume 5, December 15, 1900, written by Professor E. O. Jordan of the Chicago University, entitled, "Some Observations upon the Bacterial Self Purification of Streams."

Now, I have here some tables quoted from these reports and these reports, in their comparison, lead to the following deductions, first, that the Illinois River prior to the opening of the drainage Canal was being constantly polluted by the
1916 Illinois and Michigan Canal and to such an extent as to
give the entire water course the character of a carrier of

diluted sewage, which in a measure was proven already by the ratio of dilution that I spoke of before, showing that the dilution of sewage for the lower Illinois River, between Utica and the mouth, at times of drought was one to two.

Now, it is true that dilution, sedimentation and oxidation gradually lessen the quantity of characteristic ingredients of sewage present, but not sufficiently by the time the Illinois reaches its mouth to have completed the process of self purification; and the fact remains that all the tributaries entering the Illinois River are comparatively much purer than the Illinois itself. Now, that is a conclusion that I draw from these reports that I have mentioned just now, that the tributaries of the Illinois River are all comparatively much purer. The fact that they show low chlorines, although they all show some pollution from free ammonia, nitrites and others, sometimes quite high, the fact that the chlorines are very low would demonstrate from the standpoint of sewage pollution that these tributaries are considerably less and in some cases in an appreciable manner, to an appreciable degree less sewage polluted than the Illinois River proper, as it is analyzed in its entire course by samples taken from the entire course by these investigators whom I have quoted. 1917

MR. TODD: Is that previous to the opening of the Canal?

A. These are all conditions previous to the opening of the canal. I have not spoken of the condition of the tributaries after the opening of the canal as yet.

The second conclusion I draw, is, that there was a remarkable increase in the sewage pullution as evidenced by the higher nitrites, chlorine and free ammonia in the river since Long has examined it in 1888, and again since Palmer's investigation.

Now this pollution cannot be ascribed to accessions from the tributaries or from the Peoria and Pekin pollution, the reasons of which I will give later on when I discuss the condition of the Illinois River after the opening of the Drainage Canal, because during the same period practically no increase in the pollution from the tributaries is shown. In other words, during these long intervals between 1888, 1896 and 1899, the

Illinois River pollution continually increased, whereas the pollution from the tributaries did not increase correspondingly.

It is only necessary to consider the corresponding increase of water in the Illinois and Michigan Canal during this period between 1888 and 1896 and from 1896 to 1900 and to re-
1918 member the enormous growth of population and industries in Chicago to find the right explanation of the gradual conversion of the Illinois River at that time into a condition of very bad pollution.

Professor Palmer while declining to discuss prematurely in his report the analytical data collected for the Chicago Drainage Canal Board, nevertheless draws the following conclusion from his investigation: "Consequently, we confine ourselves for the present to merely calling attention to the fact which our results show conclusively, that the Illinois and Michigan Canal and the Illinois River were during the fall of 1895 and the year 1896, much more fully charged with sewage than they were in 1888 and 1889," the time of the extensive investigations made by Professor J. H. Long, under the direction of the State Board of Health.

"In several places we have inserted the averages of some of Professor Long's results in order to facilitate the comparison."

This is what Professor Palmer says in drawing conclusions from his investigations of the Illinois River and the tributaries in the years 1896 and 1897 as compared with previous analyses performed by Professor Long in the years 1887 and 1888.

Now, as to the examinations that I and my assistant made
1919 prior to the opening of the drainage canal, that is between August 23rd and January 22nd, at the mouth of the Illinois River above Grafton and from the Mississippi River above Grafton, I have presented a table of maximum, minimum and average results. I have got copies of these tables for the typewriters. Shall I read off that table or shall I just file it?

GENERAL CROW: Let them mark it table No. 1, Dr. Teichmann's testimony, and save time.

The table is as follows:

1920 TABLE OF MAXIMUM, MINIMUM AND AVERAGE RESULTS, 1899.

Estimated in parts per million.

Location.	Residue on evaporation.					
	Total.			Dissolved.		
	Max.	Min.	Av.	Max.	Min.	Av.
Illinois river above Grafton...	510	330	413	460	240	349
Mississippi river above Grafton	450	195	285	280	130	205

The above table gives average results of samples taken between September 6, 1899, and January 17, 1900, near the mouth of the Illinois river.

1921 TABLE OF MAXIMUM, MINIMUM AND AVERAGE RESULTS, 1899.

Estimated in parts per million.

Location.	Nitrogen, as Ammonia.					
	Free.			Albuminoid.		
	Max.	Min.	Av.	Max.	Min.	Av.
Ill. Riv. above Grafton.	0.440	0.091	0.215	0.763	0.317	0.553
Miss. Riv. above Grafton	0.134	0.030	0.069	0.614	0.394	0.503

The above table gives average results of samples taken between September 6, 1899, and January 17, 1900, near the mouth of the Illinois river.

1922 TABLE OF MAXIMUM, MINIMUM AND AVERAGE RESULTS, 1899.

Estimated in parts per million.

Location.	Nitrogen.					
	As nitrites.			As nitrates.		
	Max.	Min.	Av.	Max.	Min.	Av.
Illinois river above Grafton...	.020	.003	.012	1.1	0.4	0.8
Mississippi river above Grafton	.008	.000	.002	0.6	0.2	0.3

The above table gives average results of samples taken between September 6, 1899, and January 17, 1900, near the mouth of the Illinois river.

1923 TABLE OF MAXIMUM, MINIMUM AND AVERAGE RESULTS, 1899.

Estimated in parts per million.

Location.	Oxygen consumed.						Chlorine.		
	Total.			Dissolved.					
	Max.	Min.	Av.	Max.	Min.	Av.	Max.	Min.	Av.
Illinois river above Grafton	6.0	3.1	4.1	4.9	2.3	3.4	36	15	25
Mississippi river above Grafton	11.4	4.6	6.9	8.9	2.9	5.6	9	4	6

The above table gives average results of samples taken between September 6, 1899, and January 17, 1900, near the mouth of the Illinois river.

1924 While we notice the fluctuations in these figures it can be seen that from the original data invariably the nitrites, free ammonia and chlorines of the Illinois River were found to exceed those of the Mississippi. On September the 30th, for instance, a sample from the Illionis River contained 31 parts of chlorine per million, 44 parts per million of free ammonia and .015 parts of nitrogen in the form of nitrites. I wish to say that the free ammonia, as well as the nitrites, are to be considered as nitrogen in the form of free ammonia and nitrogen in the form of nitrites. Whereas, in the Mississippi river we find five parts of chlorine per million, .134 parts per million of nitrogen in the form of free ammonia and .002 parts per million of nitrogen in the form of nitrites, that is in the Mississippi River, above the mouth of the Illinois.

It is true that the highest albuminoid ammonia in the Mississippi River was on the same day found to be higher in the former than in the Illinois River, but it was not accompanied by correspondingly higher nitrites and chlorines. Therefore, the conclusion is justified that the sanitary character of the Mississippi River at that time was better than that of the Illinois River. As to the explanation for the higher albuminoid ammonia, which frequently corresponds with the higher or-
1925 ganic matter, to total organic matter in the Mississippi
River, I shall discuss that subject later on when I reach the second period of the investigation.

GENERAL HAMLIN (Referring to Table No. 1): Is this your own wok?

A. Yes. I wish to state that all the analyses from these samples were performed by myself personally or by my assistant, the assistant City Chemist, Mr. Buckland.

MR. TODD: That is referring to the table which has been read?

A. Yes, the table that I prepared myself. We now come to the chemical character—

MR. TODD: Doctor, have you gotten in the record the number of samples that were taken and the method of taking them?

A. Yes.

Q. I don't remember hearing it.

A. I testified to that previously, about two weeks ago and then I testified again yesterday.

Q. That is all, then. That is previous to this table?

A. Yes. I have in my regular report all the dates of those collections all entered.

GENERAL CROW: Go ahead.

A. We now come to the chemical character of the
1926 Mississippi River water between Grafton and the Intake of
the St. Louis Waterworks in 1899. As I said before, samples along this route could only be taken occasionally, when the St. Louis Harbor Boat was available for the trip to Grafton, or another boat could be engaged or a few times I sent special collectors up to take samples. All together seven trips were made from September 6th until December 4th, on the boats. Samples were taken from points, as I said before, between Grafton and Portage, Portage and Alton, Alton and Grafton and also from the mouth of the Missouri. While the analytical data thus obtained were not as complete or desirable, yet they furnished some truth in each instance of the marked polluting effect of the Illinois River on the Mississippi below Grafton.

The characteristic ingredients of sewage pollution, nitrites, free ammonia and chlorine, were certainly not as high in the Mississippi below Grafton after the junction of the two rivers as they were in the Illinois River during this time from September 6th to December 4th, but they were invariably higher in the

Mississippi after its junction with the Illinois than prior to that time and there was no doubt of the polluting effect of the Illinois River on the Mississippi.

The samples collected at that time were always taken
1927 taken from the channel, from the narrow channel running around the various dykes which have been erected in the river between the mouth of the Illinois and the mouth of the Missouri River and while the water along the shore would be of a different character than in the channel, that water coming down much slower and partially impeded in its progress on the shore, we considered the samples from the channel as giving the best criterion for the character of the water and from this narrow channel, frequently circumventing the dykes, running out from the shore we think we got comparatively good samples, samples showing the mixture of the two rivers in the channel.

I come now down to the analyses of the water of the Intake of the St. Louis Waterworks in 1899.

GENERAL HAMLIN: Now, have you a table there?

A. No. What I have here is the maximum and minimum. It is a very brief table and I have no copies. I can dictate it in a few minutes, it won't take long:

From August 23rd to September 16, 1899, four samples were collected near the intake of the waterworks, but beginning with October 16, and ending January 22, 1900, semi-weekly analyses were made at the Intake. The averages of the most important chemical constituents were as follows:

1928 Table of averages, parts per milion.

Nitrogen as free ammonia, maximum, .138
minimum, .008
average, .0063(?)

JUDGE SPRINGER: Is that the whole of that period?

A. That is the whole of that period at the Intake, yes. I will give the number of samples, 26 samples.

Nitrogen as nitrites, maximum, .01
minimum, .0
average, .002

Nitrogen as nitrates, maximum, .8
minimum, .2
average, .4

Nitrogen as chlorine,	**maximum,**	**27.**
	minimum,	**9.**
	average,	**17.**

The variable character of the water at the Intake is demonstrated by the wide range of maximum and minimum figures as shown in this table. The maximum stamps the water as polluted where as the minimum characterizes it as good potable drinking water.

1929 These great fluctuations can only be ascribed to the daily varying mixtures of the Mississippi and Missouri River waters at the Intake which is located on the edge of the channel 1,500 feet from the shore, from the Missouri shore.

Seven samples taken from the Missouri River during this period, as a rule showed nitrites and free ammonias much less than found in the Mississippi above the mouth of the Missouri.

MR. JOHNS: During what period is that?

A. That is 1899 I am speaking of now. That is, I say that the Missouri River showed much lower nitrites and free ammonias than the Mississippi above the mouth of the Missouri at that time.

On those days when the Missouri River samples were collected, the low results in nitrites and free ammonias compared with those from the intake, would be about the same in both places, provided the Missouri River water prevailed at the Intake. But whenever the Intake results were high the Mississippi River water prevailed at the Intake and the impurities then were not much less at the Intake than in the Mississippi above the mouth of the Missouri. In other words, it depended on the character of the water going into the Intake. When the 1930 Missouri River water would go into the Intake the impurities in the water at the Intake would be low. Whenever the Mississippi River water prevailed, or, comparatively, a large percentage would go in the Intake, the impurities in the Intake would go up, that is the impurities in the water would show an increase.

The relative mixtures of those two rivers I will show later on when I come to the discussion of the 1900 results. I will then present tables showing mixtures based upon chemical analyses at the Intake.

Now, as to the final conclusions on the work performed in the year 1899, I have the following to say:

The Illinois River at its mouth was badly polluted during the entire period. The Mississippi River above the mouth of the Illinois, was much better in sanitary quality than the Illinois throughout the investigation.

The Mississippi River between Grafton and the St. Louis Intake showed very much the effects of pollution from the Illinois River and on such days when the Mississippi River water entered the Intake the result would be an increased pollution of our water supply.

The Missouri River was generally purer than the Illinois above Grafton and purer than the Mississippi after its junction with the Illinois River. Do you want to ask any
1931 questions regarding that period?

GENERAL CROW: No, sir, go ahead, take up the next period of your examination.

A. The second period of the investigation covers the time from January 23rd until October 11th and extending to Dec. 1st of the same year in a measure, that is, for some points from which samples were taken, the examination was continued until November 30th, 1900. As I previously stated, on January 23rd at a conference held at the City Hall with the authorities, it was determined to enter upon an extensive investigation embodying a daily collection of samples from a number of points which I believe I mentioned on the first day of my examination.

GENERAL CROW: Well, you had better state the points from which you took these samples for analyses and the period of time.

JUDGE SPRINGER: When he states the analyses just let him state where he took them?

A. I will state the points. From January 23rd until October 11th, 3,492 samples of water were collected and analyzed from the following points:

Lake Michigan, 11,
Drainage Canal above Bear Trap Dam, Lockport, 219,
1932 Des Plaines River, Joliet, Illinois, 219,
Illinois River, 3 miles above Peoria, Ill., 260,
Illinois River, 3 miles above Grafton, Ill., 265,

Illinois River, Wesley, 1,
Illinois River, Pekin Bridge, 1,
Illinois River, 3 miles below Pekin, 1,
Mississippi River, 2 miles above Grafton, Ill., 264,
Mississippi River, 1 mile above Alton, Ill., 260,
Mississippi River, opposite Hartford, Ill., 260,
Missouri River, opposite Bellefontaine, 261,
Mississippi River, near Missouri shore, Chain of Rocks, 253,
Mississippi River, near Illinois shore, Chain of Rocks, 246,
Mississippi River at Chain of Rocks, Intake Tower, 250,
St. Louis Waterworks, wet well, 260,
St. Louis Waterworks, outlet of reservoir, 261,
Tap at City Chemist's Office, St. Louis, 156,
Harbor boat and special samples, 47,

That is, during this second period occasional trips were made by the harbor boat along the route from St. Louis to the mouth of the Illinois. These trips were made for the purpose of taking samples at various points on the same day that
1933 the collectors were taking the samples, so as to check the
results and see whether they agreed. They were in the nature of inspections. Also special samples were taken for the purpose of being assured that all samples were collected by the collectors in the right way and at the right places. After October 12th weekly samples were collected from the following points until November 30:

Lake Michigan, 5,
Lockport, Illinois and Michigan Canal, 7,
Lockport, Des Plaines River, above Chicago Drainage Canal, 7,
Lockport, Ninth St. Bridge, 7,
Lockport, Drainage Canal, Bear Trap Dam, 7,
Joliet, Des Plaines River, 7,
Illinois River, 3 miles above Peoria, 7,
Illinois River, 3 miles above Grafton, 9,
Illinois River, 3 miles above Pekin, 7,
Mississippi River, 2 miles above Grafton, 9,
Mississippi River, 1 mile above Alton, 7,

Mississippi River at Hartford, 8,
Missouri River, Bellefontaine, 7,

The reason why the authorities favored a daily collection of samples I will give later on during a discussion of the 1934 results of 1900. When I reach the conclusions I will make a statement there and give an explanation of why the daily collections were considered necessary.

Do you want any more information about the system of collection of samples, etc., how the bottles were filled, etc.?

Q. That has all been gone over.

A. Yes, sir.

Q. These samples were collected in the same manner that the samples for the bacteriological experiments were collected?

A. Yes, sir.

Q. Well, you need not go into that in detail any more then. Go ahead with your examination?

A. Shall I give the names of the assistants that were employed in the investigations and the periods of time that they were and the helpers at the distillation table and the collectors of samples?

Q. You can do that if you want to, but I don't see any use in it.

A. I will leave it to your judgment.

Q. I wouldn't put it in the record, it is not necessary.

A. All right. Do you want to ask me questions about 1935 the second period of the investigation?

Q. No, go ahead and I think you will get through quicker in that way.

A. Well, the sources of pollution in the Illinois River, are the sewage of Chicago, the sewage from the towns along the banks of the Des Plaines and Illinois River and from the tributaries. Particularly a large percentage as I have already said, according to the statement of E. O. Jordan, a large percentage of the sewage from Chicago came by way of the Illinois and Michigan Canal. I wish to emphasize, though, that this is the opinion of Prof. Jordan and later on I shall discuss the point and bring out the investigations which show that the real conditions are somewhat different from the way they were estimated by Professor Jordan. Much of the Chicago sewage today passes through the main branch of the canal.

Now, the question arises as to the Chicago sewage, how much of the Chicago sewage enters the Chicago Drainage Canal and the Illinois and Michigan Canal to-day? Under what circumstances does the sewage reach the two canals and how much sewage is still flowing into Lake Michigan? From personal observations of mine in Chicago and from investigations made by Benizette Williams, Civil Engineer, I find that there must be a distinction drawn between the sewage of Chicago directly entering the Chicago river, the south branch of the 1936 Chicago River and being discharged through the south branch of the Chicago River into the Drainage Canal directly, and the sewage discharged into the north branch of the Chicago River and into the south fork of the south branch and into the lake. I will have to refer to the figures prepared by Mr. Benizette Williams as to the population draining directly into the Chicago River, the south branch of the Chicago River, into the north branch, into the south fork of the south branch and into the lake.

JUDGE SPRINGER: Are those figures taken from his testimony in this case before this Commissioner at this time?

A. Yes sir, from his testimony. These figures show that the population tributary to the main river, that is to the south branch and to the Drainage Canal amounts to 791,677, as testified to by Mr. Williams. In other words, the sewage passing or mixing with the lake water in the Chicago River, south branch and entering the Drainage Canal, that sewage represents the drainage of a population less than 800,000.

This is the sewage that enters the main branch of the Canal.

The sewage entering the Illinois and Michigan canal, according to my observation and the testimony of Mr. Williams—I say the sewage entering or pumped into the Illinois and Michigan Canal comes from the south fork of the south branch. The sewage that enters the south branch is of a different char- 1937 acter than the sewage in the south fork. The sewage in the south fork at various times, there being no current in the south fork—

Q. The south fork of what?

A. The south fork of the south branch of the Chicago River. It is kept there for a sufficient time to enable it to undergo preliminary purification. This is not the case with the sewage entering the south branch directly that is draining from the population of 791,677. The sewage in the south fork may be compared to a septic tank. I mean the south fork may be compared to a septic tank. In order to explain what I mean I will have to describe a septic tank.

A septic tank is probably an English invention. Experiments that have been made in that line in England and finally completed at the town of Exeter, demonstrated that if sewage is run into a tank and allowed to remain in that tank one day while passing through and being discharged the following day at the other end of the tank, that this sewage undergoes certain fermentative changes. That is, there are two kinds of bacteria that will disintegrate this sewage, probably liquifying the solid matter. These bacteria are called anaerobic bacteria.

1938 They are divided into two classes, the obligatory anaerobic bacteria and the facultative anaerobic bacteria. The former, or obligatory anaerobic bacteria cannot live in the presence of oxygen. The facultative anaerobic bacteria can live both in the absence and in the presence of oxygen, dissolved oxygen of course.

Now, when the sewage enters these tanks the anearobic bacteria of both varieties attack the solid matter and liquefy it, breaking up certain organic matter into carbonaceous and nitrogenous compounds, and when the sewage leaves this tank it is in a proper condition to be finally purified by the so-called nitrofying process by the aerobic bacteria.

Now, it is not said that in these tanks aerobic action does not take place. It has been proven by experiments that in a tank aerobic bacteria may be present and may produce the so-called nitrification, which is really the oxidation of organic matter, the oxidation of the nitrogenous matter.

Now, the chemical process which the sewage undergoes in this tank is, that these anaerobic bacteria break up the organic matter as I said, and liquefy it, producing carbonic acid gas, carbonic dioxide and ammonia.

1939 Carbonate of ammonia is the form, it is so-called free ammonia. Furthermore, other gases are eliminated. If other matters are in that sewage—this sewage contains principally compounds formed by the four elements, hydrogen, nitrogen, oxygen and carbon.

Frequently there are sulphurous compounds formed, sulphuric hydrogen and sulphur being present in some of the compounds and phosphoric acid and others of an organic character that might generate. Now, when this sewage leaves these tanks it leaves it in a liquified form, there being a sludge formed in the basin of the tank. The gases, the carbon dioxide gases, have a chance to escape through certain ventilators but not permitting the admission of air, it being thought that air should be kept out as much as possible.

Now, in this tank the preliminary purification process, as I say breaks up the solid organic matter and renders it easy for the aerobic bacteria subsequently to purify it. Usually that sewage is then run through filters and by the aerobic action the purification process is completed.

Now, it has been proven that water when it stagnates facilitates, to a great extent, purification, much more so than in running streams.

1940 These investigations of the septic tank, going together with other investigations, lead to the conclusion that the faster a sewage polluted river runs directly at the point where the sewage is discharged into the canal, the longer will it take for the anaerobic bacteria to perform the preliminary work. As I said the facultative anaerobic bacteria can live in the presence of dissolved oxygen and it is evident that the purification performed by these bacteria in running waters is proven, because in spite of the presence of oxygen the facultative anaerobic bacteria can carry on the work, but wherever dissolved oxygen is absent these anaerobic bacteria or facultative anaerobic bacteria are materially assisted by the obligatory bacteria which cannot live in the presence of dissolved oxygen. These bacteria can work much more effectively. It has been proven that in septic tanks the quanity of obligatory bacteria was very small and the facultative anaerobic bacteria was very large and yet these anaerobic obligatory bacteria performed better work, were more successful in this preliminary purification process than were the facultative anaerobic bacteria than in a different tank where the reverse conditions prevailed. In other words, the most effective are always the obligatory anaerobic bacteria.

Now, the Chicago Drainage Canal contains dissolved oxy-
1941 gen. The lake water provides the Chicago Drainage Canal
with large quantities of dissolved oxygen. They vary considerably but as a whole it can be stated that they are present. There is also dissolved oxygen present in the south branch today. The south branch is very much improved over its former condition, its appearance is different, you don't find any more gas bubbles rising there except on occasions when the north branch, which has not much of a current ordinarily, is swept out by storm water. As Mr. Williams testified, there is no appreciable flow in the north branch ordinarily, that the water almost stagnates. He said the same thing about the south fork and that only when the storm seasons come and the flood waters come, or when maybe the new sewer, the Fullerton Avenue conduit, when that is in operation, which is not regularly, the volume of the sewage discharged into that river is so large that it will force a current from the north branch into the south branch. At such times and also when some pressure comes from the south fork, so that the south fork sewage instead of running and being pumped into the Illinois & Michigan Canal, as is ordinarily the case, that some of this sewage is pushed beyond that point into the south branch there, then we find the appearance of the south
branch differing very much from that ordinarily when
1942 there is a steady flow of water and a steady current
through the Chicago River, and into the Drainage Canal. In other words, the south fork and the north branch are septic tanks.

Now, while I will admit that these are not covered tanks, that these conditions are not permanent, that they are very variable according to storm waters, or according to the volume of the sewage entering the south branch through those side branches, I say that at such times of storm water, of course, you will find the appearances differing very much and the quantities of sewage that enter the drainage canal at that time, very much increased, but ordinarily at fair weather conditions the south fork and the north branch are septic tanks.

Now it might be said that the septic tank at Exeter is covered, it is true, but there is an opening for the gas to escape. The carbon dioxide has to escape or otherwise it would explode.

Then you will say that the oxygen of the air might affect the purification of the sewage.

Now, that is a question which has been investigated by quite a number of secientists, whether in the process of sewage purification in rivers, the oxygen of the air directly affects the nitrification process. This is denied and the prevailing testi-
1943 mony of scientists is to the effect that dissolved oxygen
in the water is not taken up from the air by these bacteria and that consequently what we call the aeration process does not materially change the conditions as far as the purification of sewage is concerned in streams. Now I said the prevailing testimony. I admit there are still scientists who adhere to the old principle that dissolved oxygen is absorbed by the water from the air and assists in the purification but this is denied by a great many authorities, which authorities can be produced through the literature published on the subject.

Indirectly, yes, after the sewage has reached certain stages of preliminary purification it may be that this oxygen of the air assists, but it is questioned very much.

The main point is that in the south fork and in the north branch according to these scientific investigations, it is impossible at prevailing times, not always however, but, at prevailing times, for the sewage to be assisted by the oxygen of the air in the general purification process, and since the sewage remains in there for a long time—

Q. What do you mean when you say in there, where, are you talking about?

A. I mean in the south fork and in the north branch.
1944 I mean to say that these branches are usually, not al-
ways, in the condition of a septic tank. This is an advantage to the water as it enters and leaves the drainage canal and enters the Desplaines and Illinois Rivers. But if during high water this sewage, which in low water periods is allowed to stagnate and undergo fermentative preliminary changes in the south fork and in the north branch,—representing drainage from the larger part of the population of Chicago, if that were to be all swept into the drainage canal speedily it would bring this sewage in a less purified condition than formerly into the Drain-Canal and it would vastly increase the pollution of the Drainage

Canal, and, as will be shown later on, that sewage from the Drainage Canal affects the sanitary quality of the Desplaines, the Illinois and Mississippi Rivers; and it would vastly increase the pollution of those rivers down to the mouth of the Illinois, and according to the volume of the water coming down the Mississippi, if the upper Mississippi is high, it may not affect the water at the Intake Tower much, but if the Upper Mississippi is low then the increased volume of sewage coming down those rivers must, of necessity, affect the water running into the Intake Tower of the St. Louis Water Works.

Q. Now, will you please go back to the question of the examination of that water?

1945 A. I beg pardon, Mr. Crow, but I wish to state further, that there are three conduits in course of construction in Chicago which will, as Mr. Williams in his testimony stated, eventually flush out the south fork and flush out the north branch constantly. In a measure it is being already done by the so-called Fullerton Avenue new conduit, whenever that is in operation, but it will be done still more by the Lawrence Avenue Conduit and the 39th street conduit now in course of construction. This will then carry nearly all of the remaining sewage of the City of Chicago through those conduits directly from the Chicago river into the Drainage Canal, excepting that part of the sewage, of course, still being pumped into the Illinois and Michigan Canal whenever in operation.

There will still remain the sewage of the district of Calumet and the district of Evanston, representing in toto a population of about 100,000. They will still drain into Lake Michigan.

The remaining sewage will all be discharged into the Drainage Canal at the rate of flow fixed by the United States War Department at 250,000 cubic feet per minute.

Adjourned until 2 o'clock March 17, 1903.

Southern Hotel, St. Louis, Missouri.
1946 2:00 P. M., Tuesday, March 17th, 1903.
Continuation after recess.

Present, the Commissioner and same counsel as before representing the respective parties.

DR. WILLIAM C. TIECHMANN,

Resumed the stand for further direct-examination by Attorney General Crow, and testified as follows:

Q. Just go ahead Professor?

A. In discussing the period of investigation after the opening of the Drainage Canal, which period of investigation began January 23rd, and continued until October 11th, it will be necessary to speak of certain conditions prevailing in the Illinois River valley, and its tributaries.

As I stated, the sources of pollution in the Illinois River were sewage from the City of Chicago and from the towns along the banks of the Rivers Des Plaines and Illinois, and from its tributaries.

Now in all problems dealing with sewage disposal by method of discharge of crude sewage in streams, there are two important problems to be considered,

1947 First, the oxidation or mineralization of the organic matter in the sewage with subsequent absorption of final products by plant life.

Second, the destruction of pathogenic or disease-producing bacteria.

It is now a well established fact that these changes are taking place continually in all running streams, and by means of chemical investigations, it is possible to measure comparative quantities of organic matter present, and deduce therefrom the rate of oxidation and the degree of purification effected.

The prime factor which affects the capacity of the streams to accomplish the results as outlined above, are the volume of sewage discharged into it, the degree of dilution of the same, the volume and the velocity of flow in the stream, the length of the stream and finally, the character of its water, the chemical and bacteriological character of its water.

It is essential that oxygen should be at all times available, and that the organic matter present should not be so excessive as to materially reduce the amount of oxygen dissolved in the water below that necessary for saturation. If sufficient oxygen prevails it is certain that nitrification and oxidation will take

place as rapidly as is possible with this method of dis-
1948 posal.

The chemical and bacteriological principles as outlined above are continually active in the sewage polluted waters which contribute to the water supply of St. Louis. Although the Intake of the St. Louis Water Works is located in the channel of the Mississippi River it has been shown for some years that the sanitary quality of the water supply is affected by the Missouri River which empties into the Mississippi River eight miles above the Intake as well as by the Illinois River which joins the Mississippi River above the Intake.

Now the chemical analyses made during this investigation show that the waters of the above rivers are contaminated by sewage as would be naturally expected from existing conditions. However as the fundamental object of these analyses was to ascertain the effect of the Chicago sewage on the local water supply, it will not be necessary to detail the source of pollution of the Missouri River above its mouth, and those of the Mississippi River above Grafton, Illinois. It may suffice in this connection to produce data of collections of samples and produce analytical data from the analyses of these samples from the mouth of the Missouri River, and from the Mississippi River above the mouth of the Illinois,—far enough above the mouth to exclude back water from the other rivers to interfere with the correct estimate of the analytical results.

1949 In speaking of the Illinois River valley, and the pollution of the Des Plaines and Illinois Rivers, it is necessary to enter upon a description of the construction and operation of the Chicago Drainage Canal.

ATTORNEY GENERAL CROW: Well, that has been gone over.

A. All right; I can exclude that.

Q. Just give the facts. That has been described pretty well by Dr. Ravold.

A. Well, do you want any figures on the velocity of flow in the Canal and the ratio of dilution in the canal—in the Drainage Canal?

Q. Do you know the flow of the canal?

A. The flow of the canal is about 1.92 miles per hour in the rock section, and 1.26 miles per hour in the earth section.

Q. When was that taken, after the canal was opened?

A. Yes sir, after the canal was opened.

Q. Well now, go ahead with your examination of the water?

A. Now do you want the ratios of dilution of the Chicago sewage in the Drainage Canal?

Q. Well, have you got the figures there, so you can just state the figures?

A. Yes sir.

Q. Well, what are they, what is it?

1950 A. If we take the estimate of Professor E. O. Jordan, of the amount of Chicago sewage passing through the Chicago Drainage Canal, we would obtain from ordinary calculations of the volume of sewage from the City of Chicago, based upon the water supply and the flow in the drainage canal, a ratio of dilution of one to nine.

Now this is based upon Professor Jordan's calculation. However, this calculation should be modified in the following way:

As I said this morning, the sewage of less than 800,00 population of the City of Chicago drains directly into the Chicago River, that is the south branch and mixes directly with the 250,000 cubic feet of lake water running through the Drainage Canal.

MR. WOERNER: During what time? 250,000 cubic feet per what?

A. Per minute.

Now this sewage, as I said this morning, is running to the Drainage Canal, and mixes with the water and is really the only sewage from Chicago, upon which a normal calculation should be based as to the ratio of dilution. That ratio of dilution based upon the population of say, 800,000, would make a ratio of dilution from one to about twenty-one.

Q. Well what becomes of the sewage of the other 900,000 people in Chicago?

1951 A. That drains partly into the north branch of the Chicago River and partly into the south fork of the south branch of the Chicago River, and partly, according to estimates of Engineer Benezette Williams, into the lake, the latter representing the drainage of a population of 300,000 into the waters of the lake.

Q. Don't the waters of the north branch of the Chicago River run into the south branch?

A. Yes sir.

Q. And thence into the Canal?

A. Whenever storm water and heavy rains flush out the North Branch and the south fork much of this sewage which has largely undergone an advanced stage of preliminary purification, is rushed with recent accessions of fresh sewage into the Drainage Canal. Eventually it all goes in, but I draw the distinction this morning between the sewage previously decomposed and in the preliminary stage of purification by the action of the anerobic bacteria and fresh sewages. At such times of course, when the North Branch is high and the south fork too, and they are flushed out, an increased volume of fresh sewage is rushed into the Drainage Canal, and the ratio of dilution is then considerably lower than 1 to 21.

To make an accurate estimate of that ratio of dilution at such times, is an impossibility, because of the necessity of distinguishing between the character of the two kinds of 1952 sewage, the one in the north branch of the south fork, and the other in the south branch of the Chicago River. However, as I will demonstrate from my data, whenever an increased amount of sewage was run into the Drainage Canal during my investigation, the impurities at Lockport would increase, in fact, the impurities all along the line from Chicago down to the mouth of the Illinois River would show a subsequent increase, and it is for this reason that I assert that every time an additional amount of sewage in its fresh stage is rushed into the Drainage Canal from those branches, that the impurities in the canal and the impurities in the Des Plaines River and Illinois River will invariably rise in quantity.

Q. MR. WOERNER: So that in time of rain, when these streams are high, it all goes in the Draiange Canal except the sewage from about 300,000 people; is that right?

A. Yes sir. It may be that at such times the theory of Professor Jordan may be applicable as to the true amount of sewage entering the Drainage Canal. However, it has been impossible to obtain data to settle this point and no investigation could probably ascertain the facts as to the actual amount.

Q. Well, you have covered all that now. Go ahead.

A. And as to the actual amount—owing to the methods of construction adopted for the Chicago Drainage Canal, one of the principal defects of dilution of the sewage of Chicago in
1953 the Drainage Canal, is that the dilution cannot be effected
at the point of discharge at Lockport, and lags behind operations at the Controlling Works for a time necessary to displace the entire contents of the Canal. This condition maintains at all times and produces its evil results when the dam at Lockport is raised.

For instance, when the Drainage Canal was first opened, it gradually filled with sewage from the south branch of the Chicago River at that time; from day to day this sewage accumulated, that is fresh accessions were added to the sewage in the Drainage Canal continuously for a period of about two weeks. It is true that sometimes, for instance on and after the 6th of January, the canal was opened at the Chicago end on January 1st —it is true that after the 6th day of January there was at times an overrunning of the sewage into the Des Plaines River. However, this was not measured and it cannot be ascertained how much it amounted to, but it did run over. At the same time this sewage accumulated there, and when the canal was opened on January 17th, the conditions that I mention here resulted. That is, the sewage was rushed down the Des Plaines river and the Illinois River, and produced conditions which demonstrated that the pollution was very marked of the Des Plaines River and the Illinois River subsequently, as I will show when I present
1954 the analytical data.

Something similar to that occurred in the month of September, 1900. From my own personal observations, and from the reports of my collectors. I found out that in September the Canal was practically closed at Lockport sometimes for days, and nights; sometimes only for short periods.

The official records from the Drainage Board Engineer of the flow at that time of the Drainage Canal, into the Des Plaines River, prove what I state, that owing to repairs of the dams,—and owing to repairs of the works, the Canal had to be closed, and again daily accessions of sewage in the drainage canal increased the pollution of the drainage canal and fresh sewage daily being added, intensified the obnoxious character of this sewage to a degree that when the Canal was re-opened and this water was rushed down the Des Plaines River and Illinois River, the effect of the increased pollution could be noticed from the analytical results all along the line down those two rivers.

MR. WOERNER: Just cut it down as much as you can, Professor, and go ahead.

THE WITNESS: As I say, owing to the quiescent state of this sewage, and the circumstances mentioned, of these two cases in the canal, the organic matter soon used up the oxygen
1955 dissolved in the canal water and putrification set in. Then after the dam was lowered again and the normal operations resumed the proper dilution and aeration could not be effected until the entire accumulated contents of the canal were displaced, when such a large volume of unaerated sewage is discharged there results a killing of fish, which was noticeable to my collectors of samples and a chemist of mine who came up and saw these conditions at the Lockport dam.

ATTORNEY GENERAL HAMLIN: Did you see it?

A. I didn't see it.

ATTORNEY GENERAL HAMLIN: Then I object.

A. Because I was not there during the entire time of this period.

ATTORNEY GENERAL HAMLIN: I desire to enter an objection to all this testimony given by Dr. Tiechmann which is collected from reports, and from statements made by other witnesses, as hearsay, and not as the best evidence. I have no objection to anything he saw himself, or that he did himself.

MR. WOERNER: Confine yourself to what you know, doctor, and to your theoretical knowledge with respect to this matter.

THE WITNESS: Well, in connection with the question of pollution of the Des Plaines and Illinois Rivers, I thought that was all right.

Q. Yes, that is all right, but don't state any facts of which you, yourself are not cognizant.

MR. TODD: The Sanitary District joins in the same objection with the State. 1956

THE WITNESS: I might state various defects of the canal, and chiefly engineering defects, as showing the impossibility of permitting a flow of more than 250,000 feet per minute—cubic feet per minute of the Canal, but I can go over to the chemical examination and let that matter stand.

Chemical character of the water from Lake Michigan in the harbor of Chicago.

Thirty-two samples of water were collected during the period of July 23rd to November 17th, 1900, from Lake Michigan,at various distances of from two to ten miles from Chicago.

These samples were either collected from a harbor boat kindly furnished by the Sanitary District at that time, or private boats engaged for the purpose.

Since the opening of the Drainage Canal, the condition of this lake water has changed materially, because of the diversion of the flow of the sewage in the Chicago River from the Lake to the Drainage Canal. An improvement in the quality of the water feeding the cribs has certainly taken place as is shown by the average results of our analyses, as compared with those performed by other investigators in previous years.

We find an average of .045 parts per million of nitrogen as free ammonia—

1957 Q. In what part?

A. In the water from the Lake,—from the samples—the averages that we received from these 32 samples.

Q. You mean it improved in the lake?

A. No, I am now giving the averages of the results of analyses that we obtained from samples analyzed—

Q. Now wait a minute. Just answer the question. You said that there was an improvement in the water?

A. Yes, and I am showing these improvements of the water.

Q. Now you stated that that improvement was by reason of a diversion of the sewage?

A. Yes sir, the diversion of the Chicago River.

Q. Now you mean by that that the sewage went into the Chicago River instead of the Lake, is that it or not?

A. Oh no; the sewage went into the Chicago river before the opening of the canal, and still goes into the Chicago River? but the flow of the Chicago river before the opening of the Drainage Canal was into the lake.

Q. And now it is away from the lake?

A. And now that is reversed.

Q. That is right. Now go ahead.

A. Except when the Drainage Canal is closed temporarily, then the water flows back into the Lake, as was the case in September, 1900.

1958 Q. But that is not generally the case, is it?

A. No, I wanted to explain that, but I was cut off.

Q. Go ahead?

A. We found an average of the 32 samples of water collected from July to November, 1900, of free ammonia, .045 parts per million.

Nitrogen as nitrites, .005 parts per million.

Nitrogen as nitrates, .15 parts per million.

Chlorine 6 parts per million.

And these averages would probably be still lower were it not for the fact that during September on certain days the Chicago River again flowed into the Lake because of the temporary closing of the gates at Lockport, and this resulted in a re-pollution of the water on the Lake Front, and a sample taken near Lake View crib, December 7th, contained .086 parts per million, nitrogen as free ammonia.

.014 parts per million, nitrogen as nitrites.

.2 parts per million of nitrogen as nitrates.

Six parts per million of chlorine.

This shows an increase of nitrogen in the form of free ammonia,—a double of the average, and an increase of nitrites of nearly three times the amount found during the time when the lake flowed toward the Drainage Canal.

1959 Now I wish to call attention to the fact that investigations of—

Q. Profesor, I wish as nearly as you can, you would confine yourself to the results and not state about this unless it is necessary for us to know it in order to appreciate the results.

A. Well, I want to show now that important investigation performed by George W. Rafter for the United States Government, showed that the sewage of Milwaukee runs along the shore and goes to Chicago—

Q. Runs along that far?

A. Yes sir.

ATTORNEY GENERAL HAMLIN: Wait a minute. Let's see about that. I object to that sewage of Milwaukee. There is nothing in this bill charging that?

MR. WOERNER: Well, you can answer that by stating that it does.

Q. Does your knowledge as a chemist—

A. I wish to show that the lake water is not pure water, although it is purer since the flow of the Chicago River has been changed from east to west, and that it is subject to pollution, and that investigations show that pollution from Milwaukee may affect it to some slight extent which may increase.

Q. To a greater or less extent? To some slight extent,
1960 I suppose?

A. Well, to some slight extent, which may increase with the—

Q. Make that statement?

A. Rafter says in his report—

Q. Never mind what he says. You say now that you believe that to be the fact from your knowledge as a chemist?

A. Yes sir.

Q. You need not go into the reasons that induce you to believe that now; just omit that and go on.

ATTORNEY GENERAL HAMLIN: I move to exclude from the witness' answer anything touching the sewage of Milwaukee as not being charged in this bill, and not being relevant to the issues.

THE WITNESS: Rafter, during the years of 1890—

ATTORNEY GENERAL HAMLIN: I move to exclude from the answer the statement made by the witness in reference to what the investigation made by Rafter shows.

Q. MR. WOERNER: Now just omit this Milwaukee experiment and go on with your experiments. You didn't make those experiments, did you?

A. No sir.

Q. Well, just omit that and go on with your experiments.

A. Do you want to have a description of the Illinois and Michigan Canal?

1961 Q. Yes, that is all right, but confine that as nearly as you can to the facts that are relevant and essential to the issues in this case as you understand them to be?

A. Well, I can leave out a description of the engineering features of the canal—I have the canal depth and width, and so forth,—and come right over to the subject matter.

Q. Well state, if you can, the relative sanitary conditions between the Illinois and Michigan Canal, and the Drainage Canal growing out of the differences in their construction and engineering?

A. During the last ten years, the discharge from the pumps at Bridgeport—

Q. Please do that as quickly as you can, Doctor.

A. Well I have to be explanatory in order to get in all the facts involved.

During the last ten years, the discharge from the pumps at Bridgeport, into the Illinois & Michigan Canal was practically crude sewage, after having partly been disintegraded by anaerobic action in the Chicago River, and in the branches,—in the south fork and North Branch.

The analyses of samples of the contents of the canal showed an entire absence of dissolved oxygen, without which practically no oxidation can take place.

1962 In other words, you have here in the Illinois and Michigan Canal a septic tank. The amounts of the free and albuminoid ammonias found, and the absence of nitrates and nitrites frequently also verify the above statement. The conditions prevailing in the canal are entirely similar to those of the river—overcharged with sewage and yet performing the initial purification process in an ideal way—

Q. You are not talking about the Illinois and Michigan Canal now?

A. I am talking about the Illinois and Michigan Canal now. I have to add a few things there to exemplify that. I would like to cut this very short—

Q. Never mind the exemplifications, doctor, now, you confine yourself to the Chicago Drainage Canal and point out the differences there?

A. I want to give some analytical results, proving what I have said regarding the Illinois and Michigan Canal.

Q. Well, I guess you will have to go ahead. I can't stop you. Go ahead.

A. You must excuse me, but I would like to bear out some evidence that I have stated here scientifically.

The chemical changes which take place in this Illinois and Michigan Canal are disintegration of the complex organic
1963 contents, in which similar forms, such as nitrogen, ammonia, hydrogen sulphide, etc., and a conversion of some of the suspended organic matter into dissolved constituents—

Q. Well now, you have covered that all by this statement you have made?

A. These conclusions are largely confirmed by Professor Long's analyses of 1899, by whom 27 weekly samples were taken between July 1st and November 27th, 1899, with the following results:

At Bridegport, nitrites were absent, or present only in immeasurably small quantities or amounts, for all but three of these weeks. Twice they were as high as .01, and once reached .64 parts per million.

At Lockport almost identically the same conditions were found. The nitrates at Bridgeport were uniform—absent with but one exception.

Q. Now that was before the opening of the Drainage Canal?

A. That was before the opening of the drainage canal.

ATTORNEY GENERAL HAMLIN: I move to exclude that answer as being hearsay.

THE WITNESS: From these results it is found that nitrites and nitrates are present only on rare occasions, and that practically no oxidation of organic matter takes place in the Canal, while the increase of oxygen consuming power in
1964 the filtered samples, in spite of the fact that carbon is continually escaping in the form of carbonic acid and methan, it indicates that some of the suspended organic matter has gone into solution.

At Joliet, Ilinois, in the Illinois and Michigan Canal, practically the same conditions were found as at Lockport, in regard to nitrites and nitrates.

Q. Now you are talking about before the opening of the Illinois and Michigan Canal?

A. Before the opening of the Drainage Canal.

ATTORNEY GENERAL HAMLIN: I move to exclude from the consideration of this Court all the testimony given in answer to the last question in regard to the nitrates in the Illinois and Michigan Canal at Bridgeport and Lockport, as being hearsay.

THE WITNESS: I would like to make one more short conclusion—

Q. Well now, wait a minute—

ATTORNEY GENERAL HAMLIN: Dr. Tiechmann, just let me suggest to you that this is an argument to be made by the lawyers and not by you.

Q. MR. WOERNER: Now, doctor, come down to the Drainage Canal and give us the result of your investigations.

Now doctor, as much as you can, confine yourself to your
1965 investigations and to the Drainage Canal and the waters
between the Drainage Canal and the City of St. Louis?

A. Well, now, in order to do this I would have to have my charts here. I didn't expect to reach that stage of the testimony this afternoon and I haven't got my charts here. I would have to send for those, which would probably take a half an hour to get them here. I would need those absolutely, in order to present them to the Court.

ATTORNEY GENERAL CROW: I think we can get along without them, Doctor, just go ahead. You have got there the results of your investigations?

A. Yes, but I constantly refer to the charts.

Q. Well, give it to us without the charts—without the reference to the charts and we will get the charts afterwards.

A. I have got my analytical results from Lockport. I have got them on the charts and in the records.

Q. MR. WOERNER: Now just continue the report of your investigations where you left off, and omit the reference to experiments made by others, that you were not present at and have no personal knowledge about, doctor?

A. I must leave the discussion of the data from the point of collection in the Drainage Canal at Lockport to the time when I get my data from the office.

1966 I will begin with Joliet then.

The most noteworthy features of the Joliet results were the excessively high amounts of unoxidized nitrogen as free ammonia which were present throughout the period of the investigation found at Joliet. The low nitrates at that point showed that comparatively little oxidation of the sewage had taken place thus far.

The maximum, minimum and average amounts of free ammonia found in the Des Plaines River at Joliet during these investigations were respectively:

8.284 for the maximum.
1.246 for the mimimum, and
2.759 for the average parts per million.

Now as viewed in the light of the conclusions drawn by authorities on the sanitary quality of water, Rudolph Herring states that when free ammonia is greater than 1.2 parts per million, the conditions are probably objectionable.

We find here, a maximum free ammonia of 8.284, and we find that the minimum free ammonia obtained from the analyses there is 1.246, that the minimnm found during that time is below the amount of the free amonia considered objectionable by sanitarians like Rudolph Herring for river water. The minimum was greater than the limit, I say.

The results at Joliet show the combined effect of the

1967 Drainage Canal the Illinois and Michigan Canal and the Joliet sewage.

I have to constantly refer to my charts. I think it would be better for me to go down to the office and get them.

ATTORNEY GENERAL CROW: All right, if you must have them.

RECESS until 4:00 P. M.

4:00 P. M., Tuesday, March 7th, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel, representing the respective parties.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for further direct-examination by Attorney-General Crow, and testified as follows:

Q. Now go ahead doctor?

A. This represents Chart 1, describing in curves the comparison between weekly averages of results of analyses of daily samples collected at Lockport, from the Drainage Canal, collected at Joliet after mixture of the Drainage Canal, and 1968 the Desplaines River, and also respecting the mixture of the Illinois and Michigan Canal.

The samples were taken at McDonough Street in Joliet, and samples taken three miles above Peoria. That is, the curves will show fluctuations at Lockport and Joliet, and that they produce similar fluctuations at Peoria, to show that there is little change and practically no material improvement in the Chicago sewage in traveling from the Lake Front to Lockport, and all that is accomplished by dilution is the prevention of anaerobic putrification. This is also embodied here on the map—written out, what I am stating.

Q. But the map is not in evidence.

A. This shows the—the blue line shows the Chicago Drainage Canal; its condition regarding nitrogen as free ammonia, chlorine, nitrogen as nitrates and nitrogen as nitrites.

At Lockport, Drainage Canal, the yellow line shows the Des Plaines River at McDonough Street, Joliet, and the red line shows the Illinois River, three miles above Peoria.

This represents the period from January to October, the weekly averages.

Q. Now doctor, if you will just take that map and put it down there at the table, you can go over the thing better.

A. It will show that you will find the high ammonias cor- 1969 responding there at the Des Plaines River, Joliet, and Chicago Drainage Canal, their fluctuations always go together, sometimes a little higher than in the Des Plaines River, because of the acquisition of the sewage from the Illinois and Michigan Canal where the preliminary purification has reached the stage that the Illinois and Michigan Canal shows very high —high free ammonia and you will therefore find free ammonias higher at Joliet than you will find them in the Drainage Canal.

Now take Peoria, the red line. Considerable purification has taken place of the sewage during its route from Joliet to Peoria, but you will see how the fluctuations go together pretty much. That is, you see here, for instance (indicating on map) a rise in the Drainage Canal in free ammonia, is followed by a rise of free ammonia at Joliet, and is followed by a rise of free ammonia at Peoria, and you will find here the amounts of free ammonia all figured out.

This is 1 part per million;
This is 2 parts per million,
This is 3 parts per million.

The same can be said regarding the chlorine.

Of course the crossing of the Des Plaines River at Joliet by the Illinois and Michigan Canal—the canal causes a large acquisition of the sewage there from the Illinois and Michigan
1970 Canal, and that must be taken into account in reviewing
this chart. That is what brings those high free ammonias, as I said before, at Joliet, and also brings the high chlorine up there at Joliet, running up as high as 32 parts per million of free ammonia; here as high as 54 parts per million, but you will notice that the fluctuations correspond pretty much. I don't say always, but it seems that during that period they go together pretty well.

As regards the nitrates, we find a considerable reduction now. Low nitrates you will find in the Des Plaines River and also in the Chicago Drainage Canal, that is the cycle of oxidation has not reached the stage either in the Drainage Canal or in the Des Plaines River at Joliet that we could say it is completed.

The nitrates are low, whereas, as we go down the river towards Peoria, we see the oxidizing effect of aerobic bacteria in that river, having increased the amounts of nitrates considerably.

Now let us see whether the intermediate product of oxidation,—the nitrites—which if high, demonstrate the unstability of the river, and that the river is still as far as its chemical character is concerned, in a state of change.

Let us look at those for Peoria and we will see for the summer months, an immense amount of nitrites in the Illinois River. That shows that the sewage came down 1971 gradually, and with the access of warmer weather the process of purification, as far as the change from free ammonias to nitrites is concerned, had progressed materially, and even the high nitrates running as high as over one and one-half parts per million, would indicate that for part of that sewage there had been an oxidation sufficient to say that that cycle of nitrification was completed; but not so for the entire sewage, and the extremely high nitrites, running as high as one-fifth of one part per million or .2 parts per million at Peoria during those summer months, demonstrate that the river was in a high state of fermentation, and that the oxidation process had not reached the stage yet that we could say that it was final.

In other words, the Illinois River as a result of the large accretions from the Drainage Canal, and probably also in a measure from the Illinois and Michigan Canal in its low advanced stage of purification, they cause this fermentation process to reach these enormous figures here of .2 parts per million, then down, and then up again at that time.

We will see, corresponding in a measure—we will see high nitrites coming along for the Drainage Canal, and for the 1972 Des Plaines River at Joliet. See here for instance (indicating). Now they go together very well, except in the summer, during the months of July and August, they are not so apparent any more, because of the large distances and the warmer weather there would produce conditions there at Peoria and the Drainage Canal, and the Des Plaines river, facilitating the process of oxidation materially, but not completing it as can be seen here.

I have a table of average results of daily analyses for the period from January 23rd to October 11, 1900, and I have also a table containing the maximum, minimum and average results of analyses from January 23rd to October 11, for the same year, 1900.

This would show for the Bear Trap Dam at Lockport, free ammonia on September 18th, the highest amount of free ammonia was reached at the Bear Trap Dam at Lockport,—4.8 parts per million; that is nitrogen in the form of free ammonia. I beg to emphasize that—nitrogen in the form of free ammonia at the Bear Trap Dam at Lockport was 4.8 parts per million.

The minimum was reached on May 18th,—.706 parts per million, making an average of 1.585 parts per million, which is represented on this map here.

1973 For the nitrites the maximum also at Bear Trap Dam at Lockport was .2 parts per million.

The minimum was zero.

The average was .026 parts per million, which is also noted here on the map.

Q. Now are you through with that map?

A. This is chart Number 2. The red line shows Illinois River, three miles above Grafton. The blue line represents the Illinois River three miles above Peoria.

I have here the Illinois River stages—

Q. That is the top line?

A. Yes, for the 1900 period. Now this map—

Q. Describe where it is? Describe what it is.

A. The curves representing the graphical condition of the Illinois River at Grafton, Illinois, and Peoria, Illinois during the months of January and February, 1900, prior to and immediately after the official opening of the Chicago Drainage Canal on January 17th, 1900.

Now, these results clearly show the enormous pollution caused by the flushing out of the Chicago River and the Drainage channel, and that owing to the excessive quantities of organic matter present, self-purification was practically impossible. The amounts of free ammonia, chlorine, and nitrates represented the effects produced, and although the incomplete purification is also demonstrated by the other results of the organic matter, the principal object of this chart is to make a comparison of the results at Peoria and at Grafton during the months of January and February, 1900. 1974

It will be noticed that in January, immediately after the opening of the canal, that the chlorines go up from 21 parts per million, they increase to 28 parts per million at Peoria. This is followed by an increase at Grafton from 15 to 23 parts per million, and it will be seen that the chlorines go pretty much together in their fluctuations at Peoria, as well as Grafton. You can see how they go up at Peoria. Then they go down at Peoria, and there are—and they are followed in the same way by the fluctuations at Grafton.

Now the chlorines are a splendid indication of the corresponding fluctuations in the river.

Now as regards the free ammonia, we notice the same conditions, Illinois River three miles above Grafton, as we do three miles above Peoria.

Following the opening of the Drainage Canal we find a great rise up here at Peoria, and we find a rise following soon after at Grafton, Illinois, and as this percentage decreases at Peoria, it is followed by a corresponding decrease at Grafton. In other words, the fluctuations correspond between Peoria and Grafton.

1975: Q. MR. WOERNER: Making allowance for the flow of the water?

A. Yes sir.

Now we find the river stages on top here (referring to chart) on this red line, indicating that the river rose, about January the 18th, or January 16th, it began to rise just at the time when the Drainage Canal was opened.

Now let us take a few days for the transit of the Chicago sewage there, and we get to a stationary height, continuing from January 22nd, until February 7th. After January 7th the river rises, and it rises from seven and one-half feet to ten and one-half feet; it rises four feet. During that rise we find the chlorines going down as a result of dilution produced by the increased volume of water, the flood volume of water coming down the Illinois. You will notice the same thing for nitrates and we notice the same thing for free ammonias.

MR. WOERNER: Now this is chart Number 3?

A. We find here the results at Grafton and Peoria again compared by covering a period from January until October, 1900, during the entire investigation—collection of daily samples.

We see here free ammonias,—in the Illinois River at Grafton, and free ammonias in the Illinois River at Peoria—

1976 Q. Now you mean the top line?

A. Yes sir, the top line.

We again see corresponding fluctuations in the free ammonias at Grafton, and Peoria, particularly during the early parts of the year,—during the months of January and February.

Now we find regarding the nitrates, we find a remarkable correspondence there in the fluctuations. We will see beginning with January that whenever they go down at one place, they go down at the other place. When they go up at one place they go up at the other place, again demonstrating that there is a correspondence in the results obtained from the fermentative process continuously going on in that river.

As regards the nitrites, we notice a significant correspondence of the fluctuations in nitrites results for the two points during the two months,but during the summer months, the warmer weather, facilitating the action of the aerobic bacteria in the Illinois River, we find much of those nitrites. We find them oxidized eventually, because the fluctations are not so high any more during those summer months for Grafton, as they are at Peoria.

This map again shows the enormous rise in the nitrites, due to the fermentative action of the upper Illinois River during those summer months.

1977 MR. TODD: I would like to ask you a question.

A. Yes sir.

Q. From what data is that chart constructed?

A. Those charts are prepared from the analytical data which I have collected from our analytical survey in 1900. That is, they are taken from the averages of weekly fluctuations of samples from January 23rd to October 11, 1900.

These are charts prepared by two of my assistants, who are civil engineers, but they are prepared under my direction and from my analytical data.

Now Chart Number 4, shows the results of the waters analyzed from the mouth of the Illinois River several miles above the mouth of the Illinois river, in the Illinois, and several miles above the mouth of the Illinois river in the Mississippi. They show above all, the peculiar unstability of the Illinois River at Grafton, as compared with the Mississippi River—a much more stable river, as far as its pollution is concerned, and as far as fermentative action itself takes place.

I have also here the river stages for the two rivers.

Now we see here from the river stages something that has frequently been noticed, and that is still a matter of discussion between scientists, whether the rise of a river will increase
1978 or decrease the ammonias. A rise of the river will always decrease the chlorines. There will be more water and the quantity of chlorine dissolved will diminish materially. The larger the rise of the river is, the more water there will be to dilute the chlorines.

Now regarding the ammonias, we notice in the beginning of the year, between February and March there, during the latter part of February and during the month of March, we notice a rise in the stage of the rivers, the Illinois and the Mississippi. We notice also a rise of the free ammonia in both rivers at that time, but we notice in the month of January that owing to an increased volume of sewage pollution coming down the Illinois River, we notice tremendously—I won't say tremendously high—I will say remarkably high free ammonia in the Illinois River at Grafton. It runs up as high as 1.67 parts per million of nitrogen in the form of free ammonia.

We notice also a remarkable decrease in those ammonias eventually, after normal conditions of the river had been reached these normal conditions, taking into consideration the seasonal changes produced during the summer months, we find that the free ammonia goes down low again and is almost like that of the Mississippi River at times.

But when we look at the nitrites, we notice that the Illi-
1979 nois River at Grafton throughout that year shows much higher nitrites than the Mississippi River, and we notice also the chlorines. The chlorines are much lower in the Mississippi during that entire year, and the nitrates are lower, and we notice, excepting for that peculiar rise in free ammonia in the Mississippi River during the month of March, we notice a coincidence in stability of these ammonias, with the stability as shown by the nitrites and shown by the chlorines, and the nitrates, the remarkable fluctuations here in the nitrites in the Illinois River at Grafton, in 1900. They show that the river is still

at Grafton in what we call a state of fermentative change; that is, the purification process in the Illinois River has not been completed; the nitrites are high; the intermediate product between free ammonia or carbonate and chloride of ammonia properly, and the nitrates—in the final state of the purification process—I say the intermediate stage,—the nitrites are high, and they show considerable fluctuation, demonstrating the instability of that river, and in pollution, as compared with the Mississippi River, the higher chlorines and the higher nitrites with comparatively high free ammonia, the three together representing what we call the characteristic ingredients of sewage pollution as declared by Professor Drown in his famous Massachusetts
1980 Board of Health report.

Q. MR. WOERNER: And your conclusion is?

A. That the Illinois River was very much more impure than the Mississippi River above the mouth of the Illinois during the year 1900, and was evidently in a badly polluted condition.

Now I have some notes here I want to read.

MR. WOERNER: Now are you ready to state your conclusions in general, doctor, from these charts, or do you want to give any more data from which your conclusions are reached?

A. Well, my conclusions regarding the pollution of the Illinois River; you mean, or do you mean the final conclusions? I have not reached that yet, because I have not spoken of the Mississippi River yet.

Q. Well, you have stated then what you think about the Illinois?

A. Yes sir.

Q. Well now, go on about the Mississippi. Follow your next investigation.

A. Now I have a number of points that are embodied in my report Mr. Crow, which might be brought out, and I would like to discuss those.

MR. WOERNER: With respect to these matters?

A. Yes, very important points. We have to discuss the
1981 pollution of the Illinois River by the City of Peoria, what effect it has on the river, the sanitary character of the river, and we have to discuss a few other points of value.

Q. All right, doctor, just continue along your own lines?

A. Well, I stated that the Chicago sewage is only partly purified by the time it reaches Peoria, as was shown on the chart by the high free ammonia, high nitrites and the high chlorines coming together, we must certainly admit a large amount of nitrification and oxidation between Lockport and Peoria, but it is in no sense sufficient to render the Illinois River potable by the time it reaches Peoria.

In comparison of the analytical results attained by our investigation from a point three miles above Peoria, compared with tables prepared by sanitarians, and authorities on questions of water supply, it would prove that the amounts found in our investigations three miles above Peoria, would be sufficient to establish the polluted character of the water of the Illinois river by the time it reaches Peoria.

Now I have a number of tables here from various authorities, showing what they consider a pure water, normal water, and polluted water. Do you want that to be discussed? It would take quite a time to take that matter up.

1982 MR. WOERNER: Well, that is without reference to the particular waters here?

A. No, that is only in reference to the waters of the Illinois River—

MR. WOERNER: You say you have authorities there about what is pure water and what is not, drawn from various authorities?

A. Yes and tables.

Q. Well, we won't stop for that just now, you may perhaps refer to that later, but we won't do it now.

A. All right. I have already quoted Professor Drown as having stated that high free ammonia, with high nitrites and high chlorines together, establish water as sewage polluted, and if uniformly high—they show a continuous pollution in connection with chlorine, above the normal, affording complete proof of sewage contamination.

Now regarding Peoria sewage, the population of the city of Peoria, according to the census of 1900, is 56,100 and we calculate the sewage discharge on a ratio compared with the population, that is, we figure on 150 gallons of sewage there per inhabitant. On this basis we take 8,415,000 gallons or 1,122,000 cubic

feet of sewage per 24 hours, running into the Illinois River from
the City of Peoria; that is, if we take the total poulation.
1983 But from recent data I have learned that the sewage
draining from the city of Peoria into the Illinois River
would represent only 47 per cent of the population.

MR. WOERNER: Where does the rest of it go?

A. Well, the rest of it goes into the privy vaults, the sewerage system not covering the entire system, that of course is lost in the ground.

Now as I previously stated, the minimum flow of the Illinois River at Peoria prior to the opening of the Chicago Drainage Canal, was according to Lyman E. Cooley, 72,000 cubic feet per minute. Now if we add to this the discharge from the Canal of 250,000 cubic feet per minute, we have a minimum flow of the Illinois River at Peoria of 322,000 cubic feet per minute.

Now we take the above value of 1,122,000 cubic feet of sewage per 24 hours, or 779 cubic feet per minute, and we will find that the dilution of the Peoria sewage at a low river stage, a low river stage as was recorded by Government data, government investigations and presented in the report of Lyman E. Cooley, which I have frequently quoted today, and giving this caluculation the benefit of the doubt, in so far as admitting that all the population—that the sewage from all the population of Peoria is included in this calculation, which as I say I have recently
discovered is not the case,—we find a ratio of dilution
1984 of the Peoria sewage in the Illinois River of 1 to 413.

MR. JOHNS: That is at low stage, doctor?

A. Yes, that would take the lowest stage of the river.

MR. WOERNER: Now would that materially affect the pollution of the Illinois?

A. In other words, if we take the sewage of the City of Peoria and run it into water at such a ratio of dilution, the sewage would, in my opinion, after a run of from 25 to 50 miles, be sufficiently purified with so much water added to the sewage, so as to remove the effect,—the polluting effect of the Peoria sewage on that river.

Q. Now answer the question please, the question was whether or not in your opinion the sewage from the town of Peoria materially added to the pollution of the Illinois River?

ATTORNEY-GENERAL HAMLIN: I object to that; it is assuming that the river is already polluted.

Q. MR. WOERNER: Did you get the question, doctor?

A. Yes sir.

Q. Now answer it Yes or No. The question is whether in your opinion the town of Peoria materially adds to the pollution of the Illinois River—

A. I would rather change that question, whether it has any effect.

1985 ATTORNEY-GENERAL HAMLIN: Never mind, doctor, you are not the lawyer; you are the witness.

THE WITNESS: Excuse me.

MR. WOERNER: Well, is the sewage from Peoria, in your opinion, such as to materially add to the pollution of the Illinois River

A. It adds to the pollution of the Illinois River, but only to an extent that if the Illinois River were pure, that would be what I would call a comparatively pure water, because absolutely pure water is only distilled water which you find in the laboratory, but I mean to say an ordinary good river water, potable—I will say that if it were a potable water before it came to Peoria, that the sewage entering the Illinois River from the city of Peoria would, after running from 25 to 50 miles, purify itself so as to remove the polluting effect of the Peoria sewage on the Illinois River.

Q. You mean by that chemically or bacteriologically?

ATTORNEY-GENERAL HAMLIN: That I object to as not being proper; that the answer doesn't require any explanation; it sufficiently explains itself, hence your question is not proper.

ATTORNEY-GENERAL CROW: It is a question about which counsel might differ.

1986 ATTORNEY-GENERAL HAMLIN: That is true, but we will see what the Court has to say.

MR. WOERNER: Now answer the question, whether by purification running that length of time, you mean chemically or bacteriologically?

A. Chemically yes.

Q. Do you mean that that would also be bacteriologically purified?

A. Well, that would involve a consideration of the bacterial action of facultative anaerobic bacteria and aerobic bacteria.

Q. Well, go ahead.

A. That is, would certainly have finished the purifying process after having run the distance that I have mentioned.

ATTORNEY-GENERAL CROW: Well go ahead doctor, we are waiting for you.

A. In conclusion I wish to say that the Illinois River as a whole, furnishes a good example of the inability of an excessively polluted stream, excessively polluted at the point where the Des Plaines river enters it, shows the inability of an excessively polluted stream to recover itself.

It is seen that the ability of such a stream to purity itself is dependent on the amount of sewage added, and the volume of water coming down the river, and the results at Grafton plainly show that the Illinois River is at times overloaded with sewage, and literally fails in this capacity of recovering itself or of purifying itself. 1987

WILLIAM C. TEICHMANN.

ADJOURNED until 10:00 A. M., following day, Wednesday, March 18th, 1903, at Southern Hotel, St. Louis.

1988 Southern Hotel, St. Louis Mo. 10:00 A. M. Wednesday, March 18, 1903.

Present: The Commissioner and the same Counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN

resumed the stand for further direct examination by General Crow.

Q. Go ahead Doctor?

A. I will now show the santiary condition of the Mississippi River between Grafton, Illinois and St. Louis, that is after the Mississippi River and the Illinois River join at Grafton. I have here the curves representing nitrogen as free ammonia, nitrogen as nitrates and nitrogen as nitrites.

I am testifying from Chart No. 5.

The red line represents the Illinois River three miles above Grafton.

The blue line represents the Mississippi River one mile above Grafton and the yellow line represents the Mississippi River at Hartford and the brown line represents the Mississippi
1989 River at Alton.

It will be seen that during the months of January and February (this represents 1900 from January 23rd until October 12th) that there was a marked pollution of the Illinois River water at Grafton.

You see this line coming down here, this red line, then the Mississippi River below Grafton showed a corresponding pollution and that the rise during the last week of January, that the rise in the Grafton sample,—you see the rise at Alton, one mile above Alton, the rise at Hartford, on the yellow line with a fall of the free ammonia at Grafton. We see a corresponding fall during the latter part of February and early in March of the free ammonia. We see the fall at Alton and also at Hartford, the yellow line.

During that same period from January 23rd to about the latter part of February there was no corresponding rise of free ammonia in the Mississippi River above Grafton, you see the dark line there is quite low. You find the free ammonia highest point during that period being reached as .28 parts of nitrogen in the form of free ammonia, parts per million, whereas the free ammonia in the Illinois River at Grafton—

GENERAL HAMLIN: What date was that did you say?

A. It represents its highest point on January 29th or 30th, 1900.

1990 As I say, there had been a corresponding rise in free ammonia during the preceding week at those three points, Grafton on the Illinois River, Alton in the Mississippi and Hartford in the Mississippi, and during that time the Mississippi River above the mouth of the Illinois, did not show a corresponding rise.

MR. WOERNER: Rise in what?

A. Rise in free ammonia. In other words, there were corresponding fluctuations in the ammonia, that is in rising up to very high figures and going down again later on and subsequently in the middle of March, going up again. This rise and fall, rise in free ammonia and subsequent fall in free ammonia all corresponded, demonstrating that the Illinois River pollution in free ammonia at that time affected the Mississippi River correspondingly at Alton and Grafton. The same applies to the chlorines and also to the nitrogen as nitrites. It will be seen that the fluctuations always go together as regards nitrites. It can be seen by the curves and can be noticed during the summer months, during the latter part of May and June and July and August, particularly June, July and August, as I said, you will see the rise in the quantity of nitrites corresponds in the water from Grafton, Illinois River, Hartford and Alton. You see they always go up and down together, whereas during that time this 1991 fermentation action of the nitrites did not take place to any such extent in the Mississippi River; the Mississippi River showing a comparatively even curve.

GENERAL CROW: Well, at what point in the Mississippi River?

A. Well, that is above the mouth of the Illinois in the Mississippi River.

In other words, it is again demonstrated by the results as shown here for nitrites during 1900, that high nitrites at Grafton in the Illinois River were always followed by an increase in nitrites at Alton and Hartford..

Q. What did that indicate?

A. That indicates that the Illinois River effectually pollutes the Mississippi River after joining it at Grafton.

I have here a chart No. 6, showing a comparison of the Missouri River water taken from Bellefontaine, Missouri, and the water taken from the Missouri Shore at Chain of Rocks.

MR. WOERNER: In the Mississippi?

A. Yes, sir. It will show from the chlorine, from the total solids or the total residue on evaporation, that is when a certain quantity of water is evaporated in a platinum dish and the platinum dish weighed of course, before the water is 1992 evaporated, and after evaporation of the water the residue weighed again and the difference deducted by the subtraction of the original weight of the platinum dish.

JUDGE JOHNS: What period is that?

A. That is for 1900, from January 23rd until October 12th.

It shows clearly that the water coming down the Mississippi River along the Missouri shore as it passes St. Louis, is principally consisting of Missouri River water. You have here the red line representing the Missouri River at Bellefontaine and the dark line representing the Missouri shore at Chain of Rocks. It will be seen how the chlorines run together, very close together and it will be seen from the total solids that these are almost identical, almost alike.

GENERAL CROW: Now, what time is that Doctor, the same period?

A. That is in 1900, the same period, yes sir.

I will state here that whenever the Missouri River is high and is flushed out or rather, storm water comes down the river, that there is a marked stirring up of the river and the increased sedimentation produces very high total solids or residue on evaporation. This can be seen if you look at the chart for February and March and April, where the amount of solids estimated in parts per million, rose from 800 on the 27th of February to
1993 3750 parts per million of total residue was found then in
both waters, the waters of the Missouri River at Bellefontaine as well as the Missouri River at Chain of Rocks, and the subsequent remarkable drop back again to about 1200 in the latter part of March, again shows how closely those waters resemble each other, the waters of the Missouri River at Bellefontaine and the water on the Missouri shore and you will find that all throughout this comparison.

GENERAL HAMLIN: The Missouri shore there at the Chain of Rocks?

A. Yes, sir the Missouri shore and you will find it as regards nitrites. It proved conclusively that the water that hugs the Missouri shore as it passes the water works of St. Louis at the Chain of Rocks, is practically Missouri River water. I am now speaking of the Missouri shore. I am not speaking of the channel nor of the Intake Tower, which I will discuss later.

I have here chart numbered 8. This represents a cross-section of the Chain of Rocks St. Louis, where the intake of the St. Louis Water Works is located.

GENERAL CROW: Doctor, you might just explain in that connection, in connection with your testimony, if you haven't explained it yet, what you mean by a cross-section?

A. A cross-section is a line run right straight across the
river and samples are collected right on this straight line
1994 at certain distances between the two shores. In this case
three such points were designated and the samples were
taken from each point and compared in their results on this chart. The object of this cross-section was to get an accurate estimate of the quantities of impurities in the water running along the Missouri shore representing the Missouri River water. The water going into the Intake Tower, which is located 1500 feet from the Missouri Shore, right on the edge of the narrow river channel, at that point of the river, and the third sample was taken as close to the Illinois shore as was necessary to get a sample from the water hugging the Illinois shore.

Q. What period does that map cover?

A. That represents the period of 1900 from January 23rd until October 12th.

Q. Now just explain at what point this cross-section of the river was?

A. That point is 8 miles south of the mouth of the Missouri river?

Q. That is at the Intake?

A. Yes, at the Intake Tower, just where the Intake is located. It is at the most northern city limits.
1995 I have here the total residue and the chlorine and nitrogen as nitrites. The total residue on evaporation shows
for the Missouri shore, in the red line, very high total solids nearly all the time; much higher total solids or residue on evaporation than the samples from the Illinois shore. This has been the case throughout the entire period with the exception of one occasion in March.

Q. Doctor, when you say it shows very high for the residue, you mean that there are more solids in the water after it is evaporated?

A. Yes sir.

Q. On the Missouri shore than on the Illinois shore?

A. Yes sir, that is what I mean.

Q. And when you use the term high or low, you mean there is more or less solids?

A. Yes sir.

Q. Give us those dates that you made the tests upon the solid residue after the water had been evaporated?

A. Yes sir, after the water had been evaporated. This does not represent the volume of flow because that is something entirely different. It merely is to show what the chemical proportions as far as the solids, the total solids or residue on evaporation is concerned, what the proportions are as represented
1996 in those samples. That is to what extent the mixture of the rivers takes place as far as that can be ascertained by the chemical ingredients, or rather, by this test, by applying the total solids.

Q. Well, you obtained that result by taking the total solids on either side of the river and then at the cross-section of the river and the middle and averaged the mean between the two and determined as a result that that was a mixture of the water because of the amount of solids?

A. Yes, I have a table which I shall present after resuming the discussion on these points and from my report, which will show the daily percentage calculation as obtained from this estimation based on the total solids. It shows that the Intake Tower invariably has higher total solids than the Illinois shore except on the occasion here shown on the map in the month of March when they came very close together, and the Missouri shore has, of course, always higher total solids except on the occasion there where the mixtures result in slightly higher total solids at the Intake.

Q. Now, chemically, what does that indicate?

A. The conclusion is this, that since the results at the Intake and the results at the Missouri shore differ as a rule, although they come close together sometimes, as is shown in the month of August, 1900, that there must be a mixture of the water running along the Illinois shore and of the water running
1997 along the Missouri shore.

Q. At what point?

A. At the Intake Tower. You can see here (referring to map) that the percentages at the Intake are always lower than those of the Missouri shore as already explained, with a few exceptions, and that they are always higher than on the Illinois shore. There are a few points there that demonstrate that they come close together.

Q. Now explain your other curves?

A. (Continued) and the estimates will show that.

Q. (Question repeated.)

A. The same conclusion applies to the chlorines. We find the highest chlorines in the Missouri River and also in the Missouri River water which hugs the Missouri Shore at Chain of Rocks. Then we find chlorines of the Illinois shore most of the time lower than those of the water at the Missouri shore and lower than the water at the Intake Tower, which has a few exceptions, when they come together.

Q. So that the water at the Intake Tower as a rule, is intermediate between the other two?

A. Yes. You will always find that the chlorines on the Missouri shore are higher than the chlorines at the Intake Tower, demonstrating that the water at the Intake Tower is not altogether Missouri River water which is running along
1998 the Missouri shore but is a mixture of the two currents
that run along the two shores. That applies to the channel water. Now you will see great variations in the percentage of this mixture which is due to the fact that a rise of the Missouri River will show a marked increase in the volume of water coming down the Mississippi River from the Missouri and it will at such times crowd the water that comes along the Illinois shore toward the Illinois shore and that will reduce the percentage of mixture to such an extent as to give us at such times almost pure Missouri River water or solely Missouri River water at the Intake, but at most of the times during the year this is not the case. There is a mixture there in the channel and when the Missouri River happens to be low and there is a rise in the Illinois or a rise in the upper Mississippi River, the water that hugs the Illinois shore will naturally push over to the Missouri shore and it will produce a mixture in the channel and this mixture you see represented in an invariably lower curve for the Intake, that is the blue line in the center between the two. This can be a very high percentage of Mississippi River water at times. At times

it has run as high as 100 per cent, that is, as far as we can estimate it from the total residue and chlorines it will.' They de-
monstrate that the Missouri River curve was pushed by
1999 the larger volume of Mississippi River water coming down
the Illinois shore, and was pushed so far over toward the Missouri shore that while the water at the Missouri shore nearest to the shore, would show nothing but Missouri River water in its chemical characteristics, the water running in the channel would be principally Mississippi water and would accordingly affect the quality of the water going into the Intake Tower.

Q. When you say the channel, does that mean the river location of the Intake Tower?

A. Yes sir.

Q. So that when you say 100 per cent of the water seems to be Mississippi water you mean by that the water that goes into the Intake Tower is practically all Mississippi?

A. All Mississippi water.

Q. Excluding the water that comes from the Missouri?

A. That is at that point of the river where the Intake is located 1500 feet from the Missouri shore. It may be that 500 feet nearer to the Missouri shore, there is nothing but Missouri water, but at the Intake we have, on such occasions, Mississippi River water only and the percentage tables I bring into evidence will demonstrate that.

What I said about the mixture there in regard to chlor-
2000 ines and residues on evaporation also applies to the nit-
rites. You will see here the red line representing the nitrites on the Missouri shore, which are, with one exception, in the month of March, always lower than the nitrites found in the water on the Illinois shore. The blue line representing the Intake tower shows that the nitrites are always, with two exceptions, lower than the nitrites on the Illinois shore. Now, this is another strong proof that the water going into the Intake Tower is a mixture of the two rivers, because if it were not the case, the nitrites would not be lower at the Intake Tower than they are at the Illinois shore. Of course, it happens that they are alike sometimes, but as a rule, for the larger part of the year, the nitrites in the Intake, represent a mixture of the two rivers.

Q. Now, Doctor, the exceptions that you have stated are practically insignificant are they not?

GENERAL HAMLIN: I object to the question.

GENERAL CROW: Well, state what they are.

A. Those exceptions will be shown, that is, their importance, or rather what they amount to, will be shown in a table that I am going to present, which represents the daily percentage calculation during that entire period.

Q. Can't you say it now in a few words, without going
2001 into a big explanation?

A. Well, I can by glancing over my table.

Q. Never mind, go right ahead then.

A. These exceptions are few when the nitrites at the Intake are as high as those at the Illinois shore.

Q. Isn't that all?

A. I would consider that insignificant.

GENERAL HAMLIN: Have you got a copy of that chart, Doctor?

A. No, I have not. Now, in discussing the results of the analyses of samples taken in 1900 from January 23rd until October 11th, from the Mississippi River between Grafton, Illinois and the Intake, I wish to call attention to the excessive pollution of the Mississippi River during the months of February and March as resulting from the excessive pollution of the Illinois River. I have demonstrated that from the charts.

Q. In 1900?

A. Yes. I will just take the week beginning January 30, 1900 and take the averages of the results for this week: The average free ammonia in the Illinois River at Grafton for the week beginning January 30, 1900, the nitrogen in the form of free ammonia found in the Illinois River a few miles above
Grafton amounted to 1.675 parts per million, while in the
2002 Mississippi River, a few miles above the mouth of the
Illinois, the corresponding average amounted to .175. That is only one-tenth of the free ammonia was found in the Mississippi River above the mouth of the Illinois that was found in the Illinois River at Grafton. At Alton and at Hartford we find 1.055 and .865 parts per million respectively, so that we see here from the figures a remarkable increase in free ammonia at Hartford and Alton after the two rivers had mixed. Now these samples were taken from the channel and as I explained yesterday, that is a very narrow channel circumventing a great many

dykes that run out into the river from both shores, and we can consider these samples as a pretty fair criterion of a mixture resulting from the two rivers. Now, as regards the Missouri River, I wish to state that it is noted for its great variations in the amount of suspended matter that it carries, which variations are most noticeable at the times of freshets, when it may contain as much as 4000 parts per million of suspended clay and silt.

Another characteristic feature of this water is its high chlorine contents. This high chlorine content is due to the drainage of the Kaw River through large districts in Kansas of salt deposits.

Q. The Kaw being a tributary of the Missouri at what
2003 point?

A. The Kaw is tributary to the Missouri at Kansas City.

Q. Distant about how far?

A. Well right at Kansas City.

Q. Well, distant about how far from St. Louis?

A. Well, that I couldn't tell at this moment.

In the investigation conducted in the year 1901, I had samples of water collected from the upper Missouri River above and below Kansas City and also from the Kaw River which demonstrated chemically the very high chlorines in the Kaw River as drained from these salt beds—I will refer again to the analytical data of these examinations when I come to the discussion of the fourth period, 1901.

It may suffice to state that it is positively proven that the high chlorines in the Missouri River between Kansas City and St. Louis are principally due to the drainage from these salt beds in the state of Kansas.

A very important point as regards the character of the Missouri River is the condition of the banks which owing to enormous corroding action of the current this current daily washes away large portions of the soil which is particularly the case as the river approaches its mouth.

Now, we find high suspended solids and correspondingly
2004 high albuminoid ammonias in the Missouri River. Our
examinations of the samples from Fort Bellefontaine

show that. The soil which is washed by the freshets into the Missouri River carries an abundance of organic matter contained in this soil, of vegetable origin principally. If the high albuminoid ammonias that are found in the Missouri River were due to sewage contamination they would be accompanied by high nitrites and high chlorine. Now, I have demonstrated that the high chlorines in the Missouri River between Kansas City and St. Louis are not of sewage origin, are of salt drainage origin in Kansas, because the Missouri River above Kansas City shows comparatively low chlorines.

The nitrites in the Missouri River throughout the year are low. They are frequently absent. The fact that they are low or absent and that the variations between the highest nitrites found and at times when they are absent, the variations being very small, shows that there is a very little fermentative action going on in the Missouri River, particularly as it approaches its mouth. We are justified in stating that the general chemical character of the Missouri River as it approaches the mouth is one of great stability, as I said, demonstrated by the comparatively uniform nitrites. If the nitrites were high, with
2005 the albuminoid ammonias and if the free ammonias were
very high and if high chlorines found in the Missouri were due to sewage pollution, these stable conditions would not prevail in the Missouri River. It would be in a state of change, which according to Professor Drown's now famous axiom for determining sanitary quality of river water, would be "A state of danger." This is not the case with the Missouri River. Although it may show at times, high free ammonias, it never shows high nitrites and the chlorines coming from the salt beds of Kansas, by the Kansas River, we cannot ascribe the impurities that we find at the mouth of the Missouri River, to sewage origin.

GENERAL HAMLIN: I desire to enter a motion that as there are no questions being asked I move to exclude the evidence given in reply to the last several questions in regard to the Missouri River, for the reason that it is not a statement of fact but is in the nature of an argument and it is not an opinion for the reason that no facts have been stated upon which an expert could render an opinion, are appearing in the record in regard to the Missouri River water.

GENERAL CROW: Go ahead.

A. The table of maximum, minimum and average results which I presented yesterday, contained analytical data for Fort Bellefontaine in the Missouri River.

2006 MR. WOERNER: Upon which you base your opinion?

A. Upon which I base my conclusions to-day. These tables that I refer to show that at all the times during this investigation,—the second period from January 23rd until October 12, 1900,—the Missouri River water was better in its sanitary quality than the Mississippi River water at the mouth of the Missouri River. While the averages may show free ammonias quite high in the Missouri River, the averages for the nitrites show much lower results for the Missouri river than for the Mississippi.

Q. At what point?

A. At the mouth of the Missouri. And that would stamp the Mississippi River as a more polluted stream than the Missouri River. And since the chlorines, nitrites and free ammonias in the Mississippi River at Hartford and Alton, Hartford being situated one mile above the mouth of the Missouri River, I say since those results from those points of collection at Alton and Hartford, show correspondingly high nitrites, free ammonias and chlorines, that the pollution of the Mississippi River at these points, must be principally of sewage origin.

I have here a table of the percentage calculations of which I spoke in discussing the charts of the Missouri and 2007 Mississippi River water at the Intake, the mixture as represented by the analytical results, of total solids determinations. Now, shall I offer those as evidence?

Q. Yes, have them inserted.

The tables offered by witness are numbered 1, 2, 3, 4, and 5 of Dr. Teichmann's testimony of March 18, 1903, and are as follows:

2008

PERCENTAGES OF MISSOURI AND MISSISSIPPI RIVER WATER AT THE INTAKE OF THE ST. LOUIS WATER WORKS.

CALCULATIONS BASED UPON THE DAILY ESTIMATION OF TOTAL SOLIDS IN SAMPLES COLLECTED AT BELLEFONTAINE, INTAKE AND HARTFORD, JANUARY 23RD to OCTOBER 11, 1900.

The figures from a small number of dates are missing because of the imposibility of collecting samples on some of those days. For instance, during the period from February 17th to March 3rd, when ice in the Mississippi river prevented collections at the Intake.

2030 Q. Now, Doctor, take up your map. Just state generally what that map is and indicate what the figures and curves on it represent and the object of it and state what it shows from a chemical standpoint, as to the waters that it was made from, etc.?

MR. TODD: You are referring to chart No. 9, now are you?

THE WITNESS: Yes. This chart represents a comparison of the percentage of Mississippi River water pumped at the Intake of the St. Louis Waterworks as represented by the determination of total solids or residue on evaporation, from January 23rd until October 10th, and until October 30th for the typhoid fever cases.

The percentage of Mississippi River water pumped at the Intake during this period as compared with the number of typhoid fever cases for the years representing 1895 until 1899, inclusive. An average was drawn from a number of cases reported by the physicians of St. Louis officially to the Health Department of the typhoid fever cases in St. Louis from 1895 until 1899, inclusive, and also the number of typhoid fever cases reported for the year 1900. The reason why I took the period from 1895 until 1899 was this, prior to 1895 the water pumped from the Mississippi River into the St. Louis Waterworks
2031 was pumped at a point called Bissell's Point, which is
several miles below the Chain of Rocks. In 1895 the waterworks were removed to the Chain of Rocks, and I considered it best to compare the conditions prevailing since that time because it represents the conditions as they exist in St. Louis to-day.

It will be seen from this chart that during the month of March, 1900, or rather during the month of February and during part of the month representing February 15th until about February 25th, a marked increase in the percentage of Mississippi River water in distinction from the percentage of Missouri River water which was pumped into the Intake. Following an increase in the percentage of Mississippi River water pumped into the Intake, there followed, taking into account an incubation period for typhoid fever of from two to three weeks, there followed a remarkable increase in the number of typhoid cases reported to the Health Department of St. Louis.

I also show here in the blue line the normal number of cases, or rather the average of the typhoid fever cases reported to the Health Department for 1895, 1896, 1897, 1898 and 1899. They show a very low number of cases during that period and the increase in the number of typhoid fever cases reported in March, 1900, over the average found for the
2032 five preceding years amounts to 1300 per cent. This fol-
lowed, as I said before, the large increase of percentage of Mississippi River water going into the Intake Tower previously.

Q. What do you mean by previously, what period of time?

A. You have got to take into account the incubation period. I mean several weeks preceding it.

We notice during the latter part of the summer again an increase of percentage of Mississippi River water entering the Intake and we see subsequently a large increase in the number of typhoid fever cases reported by the physicians of St. Louis to the Health Department, over the average of the five preceding years. I have got the percentage figure recorded here for those calculations. In September, 1900, the increase in the number of typhoid fever cases reported over the average of the five preceding years amounted to nearly 70 per cent.

Q. Now, what does this chart No. 10 relate to, explain the figures and curves thereon?

A. Chart No. 10 represents a comparison of the water at the Intake, the water after it has been in the reservoir for two days and just before it leaves the reservoir.

Q. St. Louis?

A. The St. Louis Reservoir.

2033 Q. The reservoir of the City of St. Louis?

A. And the tap of the water supply as we have it in the City Chemist's office.

Q. And at the Intake?

A. At the Intake, yes, sir.

Q. Explain the lines and what they mean?

A. The blue line represents the Intake, the yellow line the reservoir and the red line the tap in the City Chemist's office and the top line represents the stage of the Mississippi River at St. Louis and the number of feet are marked up here in lead pencil.

Q. On the left hand side?

A. Yes. They simply show the enormous removal of suspended matter in the subsiding reservoir; the average percentage of removal of suspended matter in the reservoirs for the period of 1900 from January 23rd until October 12th represents 85 per cent. That is 85 per cent. of the sediment of the water passing through the reservoir remains in the reservoir.

GENERAL HAMLIN: How much is that?

A. 85 per cent.

GENERAL CROW: That relates purely to the chemical contents of the water?

2034 A. Yes, sir. Now, as regards the free ammonia, we see that whenever there is a marked rise of free ammonia at the Intake, it is followed by a marked rise in free ammonia in the water of the reservoir, that is after it has practically passed through the reservoir and just before it leaves the reservoir. Whenever there is a fall in the percentage of free ammonia at the Intake, this fall is followed by a fall of free ammonia in the reservoir, in other words, increased pollution of the water entering the Intake, is always followed by increased pollution of the water in the reservoir. While the suspended matter is removed 85 per cent., the purification process that we expect of the reservoirs there, while occurring at times, such times are an exception, as is shown here on July 24th, and as a rule, there is no marked purification as far as the free ammonia is concerned in the reservoir. Whenever the Intake water is bad the sanitary quality of the water leaving the reservoir and the sanitary quality of the water drawn from the hydrants in St. Louis must be correspondingly affected. No samples were taken from the tap during that period until May 8th, but we can see from the curve here of the red line how the chemical character of the reservoir water corresponds to that of the water going

2035 into the Intake with that one exception that I recorded here, which was July 10th, during the whole year, and that fluctuation is followed again in the water as we draw it from the hydrants in St. Louis.

In other words, pollution of the water entering the Intake must affect the reservoir water; it must affect the water leaving the hydrants of St. Louis. The same applies to nitrites. We can see here how the nitrites run very close together for the Intake and the reservoir during the first four months of 1900, and that when they go down again they go down together. Fluctuations always correspond between the Intake, the reservoir, and the tap.

Now, I wish to call attention to a marked increase in pollution of the water at the Intake during the early part of 1900. You will see that there is a tremendous rise in the free ammonia and you will see a tremendous rise in nitrites. You will see these rises going together during those months.

GENERAL CROW: What indicate those rises?

A. It indicates a remarkable pollution of the water supply of St. Louis during that period.

Q. What, show it on that map? I want to get that into the record.

A. The ammonia lines and the nitrite lines.

2036 Q. Well, the curves?

A. The curves show that. From all available data regarding water collected from the Mississippi river at the Intake and from the water collected from the reservoirs at St. Louis, and from the water analyzed from the hydrants of St. Louis—I say in all the data that we could get, we tried to get the results of all the analyses that have been made. There are analyses on record that were made by chemists during the last 20 years. None of these analytical results ever showed such a remarkable quantity of free ammonia and corresponding with it a large increase in nitrites, at the Intake Tower or the reservoir, or the water of the hydrants of the City of St. Louis. This marked increase of pollution of the St. Louis water supply during the early part of 1900, not only followed a marked increase of pollution in the Mississippi River between Grafton and the Intake Tower. It followed a marked increase in pollution in the Illinois River at Grafton at a time when there was no marked increase of pollution in the Mississippi River above the mouth of the Illinois. It followed a marked increase of pollution at Peoria, I mean at the point of collection of samples three miles above the City of Peoria, and a marked increase of pollution of samples taken from Joliet and Lockport.

In other words, there was a wave of pollution coming
2037 down the Des Plaines River, the Illinois River, entering the Mississippi River at Grafton, running along the Illinois shore opposite the St. Louis Waterworks at Chain of Rocks. and, as shown by the percentage mixture entering the Intake of the Waterworks of St. Louis. We find during that period the percentage of Mississippi River water entering the Intake varying from 19 to 100 per cent.

Q. During this period?

A. During this early period of 1900.

Q. That was after the opening of the Canal?

A. After the opening of the Drainage Canal.

Q. Now Doctor, state what is the result of your conclusions from the map and from the tables you have there concerning these facts from a chemical standpoint?

A. (No answer.)

Q. Now, Doctor, have you any data comparing the chemical results of the analyzation of these waters for the period of 1899 and 1900 covered by your examination?

A. Yes, sir.

Q. Please state them?

A. Generally comparing the results of the analyses of waters collected between Grafton, Illinois River and the Mississippi River and the St. Louis Intake, and also from the
2038 Missouri River for the periods of 1899 and 1900, we notice from the averages an increase in the nitrites and free ammonia in 1900 as compared with 1899, for the route between Grafton, Illinois, and the St. Louis Intake. It shows that the sanitary character of the water as discharged by the Illinois River into the Mississippi at Grafton was more polluted in 1900 than in 1899, and it shows that this increased pollution of the Illinois River as found in the samples taken from Grafton, resulted in an increased pollution of the Mississippi River at Alton and Hartford for 1900 over 1899, and furthermore shows that this increased pollution of the water between Grafton, Illinois, and Hartford was extended to the water going into the Intake tower. In other words, our analytical results show that the water entering the Intake in 1900 was more polluted than the water entering the Intake in 1899, and that the increased pollution, since there was no corresponding increased pollution in the Mississippi River above the mouth of the Illinois, nor was there an increased pollution in the Missouri River above its mouth, it shows that the increased pollution of the water going into the Intake Tower must be ascribed to the increased pollution of the Illinois River in 1900, and since I have shown that the increased pollution of the Illinois River at Grafton was
2039 due to the increased pollution of the Des Plaines River following the opening of the Drainage Canal, I feel justified in declaring that the opening of the Drainage Canal resulted in an increased pollution of our water supply.

Q. Now, there is another period of examination following that, isn't there?

A. Yes, sir.

Q. Is there anything further that you want to say in that connection?

A. Yes, but I haven't got my report on that. That is down stairs in your room, and I might take that up after lunch. It being in that period.

Adjourned until 2 p. m., March 18, 1903.

2040 Southern Hotel, St. Louis, Mo. 2 p. m., Wednesday, March 18, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same Counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN resumed the stand for further direct examination, by Attorney-General Crow, and testified as follows:

Q. Professor, did you make any investigations after the one that closed in October, 1900?

A. Yes, sir; a number of samples were still collected between October 12th and November 30th, from points in the Illinois River, and these samples were promptly analyzed at the City Chemist's office. But these samples were not collected daily, and, therefore, in the general view and the averages that I have drawn from the tables, this analysis of samples collected outside of St. Louis are not included.

Q. Well, you have the result of your investigation, have you?

A. Yes, sir

Q. What period of time did it cover?

A. For the samples taken outside of St. Louis, October 12th to November 30th. Then we quit taking samples outside of St. Louis, but from October 12 to November 30, 2041
1901, the third period of investigation, covered in addition to those sporadic samples outside of St. Louis, they covered the analyses of samples collected daily at the Chain of Rocks opposite the St. Louis Waterworks in the Mississippi River.

A daily sample during this period was collected at the Chain of Rocks from the Mississippi River close to the Illinois shore. Then a sample close to the Missouri shore.

A sample was also taken from the water right at the entrance of the Intake Tower and one sample was taken from what is called the outlet chamber of the St. Louis Water Works. That is after the water has slowly passed through the reservoir covering an average period of about two days, it passes through a small chamber called the outlet chamber, and from there is distributed into the mains over the city of St. Louis.

A daily sample was taken in this outlet chamber and one was daily taken from the tap in the City Chemist's office.

The object of this continued survey in its limited form was to obtain a consecutive daily record of the daily character of the St. Louis Water supply.

Q. Well, will you please give the results of that?

A. Yes. Well, I am briefly summarizing in a few words, the results for this period.

2042 The analytical data thus collected have all been noted down in the report which can be presented if required. They demonstrate the continued polluted character of the St. Louis water supply during this period.

Furthermore, that the water along the Illinois shore during this period was at all times more polluted than the water running along the Missouri shore and that during such periods when a mixture of the waters from these two rivers entered the Intake, as occurred frequently on such occasions, the impurities found in the samples from the Intake were higher than those found in the samples from the Missouri shore, indicating that the mixing of the two currents in the narrow channel on the edge of which the Intake Tower is located, invariably resulted in an increased pollution of our water supply.

The next period of investigation, the fourth period, covers the time from October 1st, 1901 to November 30, 1901. It was the most comprehensive investigation conducted since the beginning of the analytical survey of these waters in August, 1899.

It was our endeavor to obtain samples from all points along the route between Chicago and St. Louis, which would give us information regarding the subject of whether or not sewage from the city of Chicago pollutes the St. Louis water 2043 supply.

I, therefore, collected samples and had them shipped to the City Chemist's office from the following points during this two months' investigation and the samples were collected daily from the points that I mention now.

Chicago, Bridgeport, Illinois and Michigan Canal.
Chicago, Bridgeport, Chicago Drainage Canal.
Lockport, Chicago Drainage Canal, Bear Trap Dam.
Lockport, Illinois and Michigan Canal.
Desplaines River above Bear Trap Dam at Lockport.
Desplaines River at 9th Street Bridge, Lockport.
Desplaines River at Ruby Street Bridge, Joliet.
Desplaines River at Brandon's Bridge, Joliet.

Now, I wish to say in explaining these various points, that we endeavored to obtain, by taking samples at those points, analytical data of the character of the Illinois and Michigan Canal, the sanitary character of the Illinois and Michigan Canal, of the Chicago Drainage Canal at its entrance and at the western end at the Bear Trap Dam. Also, from the Illinois and Michigan Canal at Lockport before it crosses the river at Desplaines, which it does in the City of Joliet. Then, from the
2044 Desplaines river before it meets the Drainage Canal or rather before the water from the Drainage Canal enters the Desplaines River.

Then, from Ninth Street Bridge, Lockport, after the Drainage Canal has entered the River Desplaines.

At Ruby Street, Joliet, before the Illinois and Michigan Canal enters the Desplaines River and before any sewage from Joliet could possibly enter the River Desplaines.

Then at Brandon's Bridge, Joliet, from the Desplaines River, after the Illinois and Michigan Canal has crossed the Desplaines River and after the sewage from Joliet had been discharged into the Desplaines River.

Then we had daily samples collected from the Illinois River at La Salle, from Peoria, Illinois, three miles above the railroad bridge, what is called the Narrows, ordinarily, then at Pekin, Illinois, from a point where the Pekin Bridge is located, then at Kingston, Illinois, eight miles below Pekin and at Beardstown, Illinois.

These samples were all taken from the Illinois River and at Grafton several miles above the mouth of the Illinois River.

Then, the following samples were taken from the Mississippi River.

2045 At Grafton several miles above the mouth of the Illinois River.

At Alton, one mile above Alton.

At Hartford, Illinois, which is located one mile above the mouth of the Missouri River.

Then, at the Chain of Rocks, St. Louis Water Works, Illinois shore.

Chain of Rocks, mid-stream.

Chain of Rocks at the Intake Tower of the Water Works.

Chain of Rocks, Missouri Shore.

Missouri River, Fort Bellefontaine.

St. Louis Water Works at Outlet Screen or Outlet Chamber, rather. It is given both names but I will call it Outlet Chamber, as the better name.

From the tap in the St. Louis City Chemist's office.

During these two months, tri-weekly samples were collected from Lake Michigan at Chicago.

Q. At what point in the lake were they taken?

A. Well, that was—it was arranged there by the collector who lives in the City of Chicago, that he should go out in a boat to the various cribs, just according to arrangements that he could make at that time, but he always got samples
2046 of the Lake Michigan water from what could be considered Lake Michigan water proper.

Semi-weekly samples were taken from the South Branch or rather the South Fork of the South Branch of the Chicago River.

Semi-weekly samples were also taken from the Illinois River at Wesley, Illinois, a point between Peoria and Pekin, and these samples at Wesley were taken close to the right and left shore and in the center of the Illinois River, a cross-section, so to speak, four samples were collected during these few months, from the Missouri River at Omaha, above and below the city.

Four samples from the Missouri River at Kansas City, above and below the city.

Four from the Missouri River at Jefferson City, above and below the city.

Four from the Missouri River at Herman, Missouri, above and below the city.

Four from the Missouri River at St. Charles, Missouri, above and below the city.

Two samples were taken from the Missouri River at Wathena, Kansas. That is at a point above Kansas City.

Q. Above the mouth of the Kaw River?

A. Yes. Two samples were taken from the Missouri
2047 River at St. Joseph, Missouri, above and below the city.

Two samples were taken from the Kaw River which empties into the Missouri River at Kansas City.

The samples were taken at a point near Argentine, Kansas.

During this period also, cross-sections of samples were taken at Pekin Bridge, Illinois River,

At Kingston, Illinois river,

At Peoria, Illinois River,

At Joliet, Des Plaines River,

At Alton, Mississippi River,

At the Chain of Rocks, Mississippi River,

At Hartford, Mississippi River,

At Fort Bellefontaine, Missouri River.

After the cessation of the collection of daily samples from the river above the Chain of Rocks, outside of St. Louis, daily collections were still continued at Grafton, Illinois, from the Illinois, from the Illinois River until December 18th, 1901. Since that time no additional samples have been taken from any points above the City of St. Louis.

Q. 1901 or 1902?

A. Yes, 1901.

ATTORNEY GENERAL HAMLIN: Are those which you have just been stating—I thought they were 1902?

2048 A. No sir, 1901. The first period of investigation was
from August 23rd until January 22nd, 1900; the second period of investigation was the big investigation of 1900, from January 23rd until October 12th, covering the collection and analyses of a large number of samples from the route between Chicago and St. Louis, the number of occasional samples were still taken after October 12th, until November 30th, 1900, from

points along the Illinois River and Mississippi above St. Louis, and daily samples were taken during this third period of investigation from October 12th, 1900, until September 30th, 1901.

Five daily samples were taken, three from the Mississippi River at the Chain of Rocks, and one from the Outlet Chamber of the St. Louis Water Works, and the fifth sample was taken from the tap in the City Chemist's office,—daily samples.

Then on October 1st, the large investigation, covering collection and analyses of samples outside of St. Louis was resumed, and continued until December 1st.

ATTORNEY GENERAL HAMLIN: 1901?

A. 1901. And then I said that no samples were collected outside of St. Louis after December 1st, 1901, excepting from the Illinois River several miles above the mouth of the Illinois at Grafton and from the Mississippi above Grafton. This was kept up until December 18th.

2049 Q. ATTORNEY GENERAL CROW: Of what year?

A. December 18th, 1901.

Q. Well, that is the third period of investigation?

A. Yes. No, this is the fourth period, you see, the second and fourth periods were the periods covering the investigation outside of St. Louis, and the first period covered investigation up to Grafton, Illinois, and the third period covered investigation only at the Chain of Rocks. That was simply to keep a check on the character of the City water supply.

Now the resumption of the collection and analyses of samples along the water route from Chicago to St. Louis in October and November, 1901, was undertaken for the chief purpose of ascertaining whether the continued operation of the Chicago Drainage Canal during the interval between the cessation of the investigation in October, 1900, and the resumption of the investigation for samples outside of St. Louis in October, 1900, had produced any improvement of the sanitary conditions of the water as established by the former investigation along this route in 1900.

I will now present a number of charts, briefly explaining these conditions as we found them.

These charts were prepared under my directions by the

same engineers who prepared the charts for the investi-
2050 gation of 1900, presented this morning, Mr. Alexander
N. Miller, and Mr. William H. Goetz, so that I may say that I did not prepare the charts myself, but that we consulted over the method of preparing them and the data, etc., and the charts themselves were prepared by Messrs. Miller and Goetz.

Q. MR. TODD: Are those charts made up from the examination of the waters that you have just described, as being taken at these different places?

A. Yes sir, they have been.

MR. TODD: I want to interpose an objection on the ground that the water that has been testified to here as being taken at these points,—there is no evidence to show that they were really taken at those points at the time and place as indicated.

ATTORNEY GENERAL CROW: Well, we went into that before your arrival.

MR. TODD: Have you proven that at each place?

ATTORNEY GENERAL CROW: We put a man on the stand that we sent up the Missouri River as far as Omaha.

MR. TODD: Well I mean for any points that have not been proven; we know that some points have been proven, but I don't know whether every one of them has or not.

Q. ATTORNEY GENERAL CROW: Now what is the chart that you have there and what does it represent, and please explain the curves and figures thereon.

2051 MR. TODD: What is the number of that, doctor?

A. We will number that No. 1, 1901, Chart No. 1, 1901.

ATTORNEY GENERAL HAMLIN: Now I want to put in the record his statement in regard to that chart, that he is testifying from, for the reason that I don't think it is permissable for him to testify to that chart.

ATTORNEY GENERAL CROW: Well, in order to save the record I can offer the memorandum or whatever he has got there,—analytical sheets there.

ATTORNEY GENERAL HAMLIN: But he doesn't say that he made the comparison.

ATTORNEY GENERAL CROW: But they were made under his supervision, in his office—were they or were they not, professor?

A. Yes sir, they were made under my supervision and I carefully scrutinized the original records as presented by the chemists, as well as the entry sheets prepared by the clerk from those records, in order to form my conclusions on the results of the analyses.

Q. Who made the sheets?

A. They were made by my clerk at that time.

Q. Where did the data come from that they were made from?

A. The data came from the original record books of the various assistant chemists.

MR. WOERNER: You can get their testimony, can't you?

A. Yes sir.

2052 ATTORNEY GENERAL HAMLIN: As I understand from you, you did not make this chart?

A. No sir, I did not.

Q. And I understand further that the tables from which this chart was made, you didn't make?

A. No sir. They were made by my assistants.

Q. That all the data from which this chart was made was obtained by someone else than you—other than you?

A. Yes, under my direction and supervision.

Q. Well, what do you mean by under your direction and supervision?

A. Well, when I started on this large investigation, I carefully mapped out a system of collection of samples of water. I selected the points of collection myself, and I prepared a system of analyses, designating the tests to be made, and selecting personally the assistant chemists, among whom the various tests were divided, and they were all instructed to perform these analyses in methods that we carefully discussed with them and decided upon finally, and sanctioned by me personally before they entered on these analyses, and then they all received their books and had their names on their books, and these books had also the name of the test performed, and the analytical data that each assistant chemist obtained were entered in his particular book, and these books at the conclusion of the work
2053 were all turned over to me.

Q. Now the investigations that you directed to be made were made by some one else besides you, that is the tests were made by your assistants, and not by you?

A. Yes sir.

Q. And you took their report of those tests as being correct?

A. Yes sir.

Q. Not from any knowledge that you had of the tests, but from the report that they made to you?

A. Well, I had knowledge of their tests, because I was constantly in the various rooms of the laboratory during the time that they were working, except when I was attending to business connected with the investigation in a different building, called the New City Hall.

Whenever I was in the laboratory I would observe their work and carefully note the character of their work, and discuss the various features of the analytical work with them, as the work proceeded, during these two months, that is, I considered that as supervision of the work.

Q. And then this chart was made from the examinations that your assistants made?

A. Yes sir. One of the chemists that took part in that
2054 investigation is here in the room, Mr. Miller. He performed certain tests and frequently consulted me regarding those tests and the results obtained, etc.

Q. This chart was made not from the books, but from a general report that was prepared from the books, is that right?

A. No, they were made from those books.

ATTORNEY GENERAL HAMLIN: Well, you can go ahead and I will reserve the right to object further along.

BY ATTORNEY GENERAL CROW:

Q. This work was done under your personal supervision?

A. Yes sir.

Q. And was your work, and you were responsible for it?

A. Yes sir.

Q. It would have been impossible for you or any other man to have carried out all the details of this work yourself?

A. Yes sir.

Q. And it is the customary method that is pursued in doing this class of chemical work, by a chemist?

A. Yes sir.

Q. He has assistants?

A. Yes sir.

ATTORNEY GENERAL HAMLIN: I think that is true if it is followed up by the assistants. I think you are right about that, General.

2055 ATTORNEY GENERAL CROW: I think so, where they are all working on one thing, you know. You will meet the same proposition when you come to your people, you know.

ATTORNEY GENERAL HAMLIN: I will see when we get further along, if we want to, I will ask to confirm it by the assistants.

ATTORNEY GENERAL CROW: Yes, if you want to, we will put the men on.

Q. Go ahead, Professor?

A. This is chart Number 1 for the investigation of 1901, October and November.

MR. TODD: I would suggest that you follow it consecutively. Ten was the last one.

ATTORNEY GENERAL CROW: Yes, I think that will be better.

(Chart No. 11.)

A. This chart represents a comparison of results obtained from the analyses of water in the months of October and November, 1901, from the Illinois and Michigan Canal at Lockport; from the Desplaines River at Brandon's Bridge, Joliet; from the Drainage Canal, Bear Trap Dam, Lockport, and from the Desplaines River, above Bear Trap Dam at Lockport.

The red line represents the Illinois and Michigan Canal.

2056 The blue line represents the Desplaines River at Brandon's bridge, Joliet.

The green line represents the Drainage Canal, Bear Trap Dam, Lockport, and the yellow line represents the Desplaines River above the Drainage Canal, that is before they meet.

It will be seen from this chart that during that period the Illinois and Michigan Canal was highly charged with free ammonia. It reached the figure of 22.4 parts per million of nitrogen in the form of free ammonia. During the last week a considerable fluctuation can be noted and at the time the collection and analyses was started the amount represented the figure of

19.8 parts per million of nitrogen as free ammonia. In a few weeks this figure was lowered down to 15.2 parts per million. It went up enormously, up to 22.1 parts per million during the period from October 25th until November 8th, and then down again within one week from 22.1 to 18.7 and then during one week went up again to the highest figure or amount, 22.4.

The same is true as to the chlorines found in the Illinois and Michigan Canal at that time. We see variations there in the chlorine representing parts per million from 106 up to 150.8; then going down again within one week to 120.6; going up again and reaching the high figure of 169.5; then jumping down again, away down to the figure of 128 parts per million
2057 and then rising again.

If we look at the nitrites we find fluctuations in the nitrites but notice that the nitrites do not fluctuate as much as the free ammonia and the chlorines. They are either absent as is seen here from the results and at times, for two weeks, the first two weeks, there are no nitrites in the Illinois and Michigan Canal. Then they rise up a little, up to 0.002 and 0.003. Then we find great fluctuations there in the nitrates representing a minimum of .007 and a maximum of .15.

Now, that would indicate that the Illinois and Michigan Canal at that time was in a great state of fermentation. The action of the facultative anaerobic bacteria in this canal resulted in a considerable advance in the initial process of purification usually performed by these bacteria.

The variations in chlorine show that the amount of sewage coming into the Illinois and Michigan Canal during this time, together with the varying amounts of free ammonia and nitrites, that the amount of sewage pumped into that canal must have been of great variable quantity. The water condition at that time may have influenced the action of the anaerobic bacteria somewhat and as it is an established fact that during the colder season of the year the purification process in the rivers
2058 is retarded considerably, the results would in a measure explain themselves.

Now, if we compare the results for free ammonia with the results obtained from the main Drainage Canal at that time, represented by the green line, we see considerably less free ammonias in the main Drainage Canal than we find in the Illinois and Michigan Canal.

If we take the results obtained from the Desplaines River at Brandon's Bridge, where we have the sewage from the two canals and the sewage of Joliet included—we find that represented in the blue line there—we find more free ammonia and we find more cholrine and we find more nitrites and more nitrates in the Desplaines River at Brandon's Bridge, Joliet, partly due to the accessions of sewage from the Illinois and Michigan Canal at that time.

We also see that after the sewage from the canal has entered the Desplaines river—

ATTORNEY GENERAL CROW: Both canals?

A. Both canals at the Desplaines River. The sewage in the Drainage Canal being in a less advanced stage of purification as shown by the lower ammonia, than the sewage in the Illinois and Michigan Canal, we see a marked increase in nitrites. These nitrites at Brandon's bridge, Desplaines River, run very high, much higher than the nitrites in the Drainage Canal; 2059 much higher than the nitrites in the Illinois and Michigan Canal. This was due to the fact that when the Desplaines River mixed with the sewage from these two canals the aerobic bacteria prevailing in the much purer Desplaines River, assisted materially in performing the purification process in the Desplaines River. However, the very high nitrites in the Desplaines River after the two canals mix with the Desplaines River at Joliet, show that the process of purification was in an intermediate stage as yet. That is, the fermentative action was still going on and it was going on still in its preliminary stage as is seen by the comparatively high free ammonias during that period. You take the blue line there, it represents the Desplaines River at Brandon's Bridge. We have free ammonia there, 3.2 parts per million, which stamps that water as sewage. The highest found was on the 4th of October, the first week when we began—

Q. At what point?

A. At Brandon's Bridge in the Desplaines River. That is after the canals had mixed with the Desplaines River. After the preliminary more advanced purified sewage from the Illinois

and Michigan struck the Desplaines and the less advanced purified sewage from the Drainage Canal was discharged into the Desplaines River, a tremendous pollution of the Des-
2060 plaines river took place. This is shown, as I said before, by the amount of free ammonia being shown on this chart found at Brandon's Bridge,in the Desplaines River,amounting to a maximum of 3.2 parts per million and a minimum October 25th of 2.3 parts per million. The minimum amount there is the characteristic amount for sewage and a large amount of course, stands for a still higher sewage polluted river. If we take the Desplaines River before it reaches the Drainage Canal we find very high free ammonia in the Desplaines River. It amounts to .1 part per million for two weeks. Then it goes down to about .005 parts per million and remains that way for the five weeks following this very slight, inappreciable, rise.

Q. That is above the Drainage Canal?

A. Above the Drainage Canal and above the Illinois and Michigan Canal.

Now, we take nitrites. We find correspondingly low nitrites in the Desplaines River before the Illinois and Michigan Canal and the Chicago Drainage Canal strike it. These nitrites are remarkably low. At times there are no nitrites in this river and since there is such a small amount of free ammonia in that river and the chlorines are exceedingly low, we must call this—the Desplaines River before it is polluted by the sewage from the Drainage Canal and the sewage from the Illinois and
2061 Michigan Canal, a comparatively potable river water.

After the main Drainage Canal strikes the Desplaines River, the main Drainage Canal showing at that time, during those months, a maximum amount of free ammonia of 1.3 parts per million, a very high amount of free ammonia, which stamps the Canal as badly sewage polluted at Lockport. We find that the Drainage Canal and the Illinois and Michigan Canal after they strike the Desplaines River, increase the amount of free ammonia remarkably. They increase the amount of chlorine; they increase the amount of nitrogen as nitrites very much. In other words, the comparatively pure Desplaines River is badly sewage polluted by the main Drainage Canal and by the Illinois and Michigan Canal as demonstrated by this chart.

The conclusion was drawn from the samples collected daily at those points for the two months, October and November, 1901, and since the sewage in the main Drainage Canal was at that time not as much purified, in its preliminary stage, as the sewage in the Illinois and Michigan Canal and as to the sewage in the Drainage Canal in volume, as mixed with the water of the Drainage Canal represents a much larger percentage of sewage
2062 than its total volume discharged into the Desplaines River, this pollution must largely be, and the somewhat dangerous pollution must largely be attributed to the accession —this pollution of the Desplaines River must largely be attributed to the main Drainage Canal, because of its less advanced state of preliminary purification.

MR. WOERNER: By main Drainage Canal do you mean the Chicago Drainage Canal?

A. Well, that is the Drainage canal which enters or connects with the Desplaines River at Lockport.

MR. TODD: The data from which this map was made only goes to Brandon's road?

A. Brandon's Bridge, yes. The comparisons are made at Brandon's Bridge. This map is principally to show the effect of the pollution of the Desplaines River by the Drainage Canal and the Illinois and Michigan Canal, the pollution being comparatively greater and more effective as a factor of pollution than that of the Illinois and Michigan Canal.

ATTORNEY GENERAL CROW: Now, Professor, what does that chart No. 12 represent?

A. This is a map giving a comparison of analytical results obtained from the daily collection of samples of water taken from the Desplaines River above Bear trap Dam,
2063 taken from the Desplaines River at the Ninth Street Bridge in Lockport, that is at the point in the Desplaines River above the point where the Illinois and Michigan Canal crosses the Desplaines River and at Brandon's Bridge, Joliet.

Q. Now, please explain the curves and the figures on the map, and the colors?

A. Yes. In other words, it shows you the result of the mixture of the water from the Drainage Canal and the Desplaines River and the result of the mixture of the Desplaines River, the

Drainage Canal and the Joliet sewage in the Illinois and Michigan Canal.

The green line represents Brandon's Bridge at Joliet.

The red line represents the Desplaines River at Ninth Street Bridge, Lockport, and the black line or the partly black line and partly blue line—the dark line, in other words, represents the Desplaines River above the Bear Trap Dam. If you will look at that dark line—

MR. TODD: Is this map made substantially as you have testified in regard to the other charts?

A. Yes, just as I have mentioned.

You will see the dark line showing quite low free ammonia, the highest being .2 parts per million and the lowest being .1 part per million. 2064

The Desplaines River at Ninth Street Bridge, Lockport, which represents the mixture of the water from the Drainage Canal and the Desplaines River just above the point where the Joliet sewage enters the Desplaines River, and above the point where the Illinois and Michigan Canal crosses the Desplaines River, you have represented in the enormous figure for free ammonia of 1.3 parts per million of free ammonia. That is the maximum. And the minimum during this time, during these two months, of .85 parts per million.

If we compare the chlorines—I mean if we compare the nitrites with the free ammonia, we notice that the Desplaines River for several weeks shows no nitrites and, going with comparatively low free ammonia would demonstrate a purity of the stream far superior to that of the Desplaines River after it receives the accessions of the sewage entering the Desplaines River from the main Drainage Canal. We find that represented in the increase in nitrites from zero or no nitrites at the beginning of this investigation up to .02 parts per million. 2065 The maximum nitrites reached during this period at Ninth Street Bridge amounts to .03 parts per million which is comparatively high.

In other words, if we set aside the pollution from the Illinois and Michigan Canal and the Joliet sewage, we find that the main Drainage Canal pollutes the Desplaines River before the Illinois and Michigan Canal and before the Joliet sewage are discharged into the Desplaines River to such an extent as to stamp the Desplaines River as a highly sewage polluted stream owing to accessions of the sewage discharged from the Chicago Drainage Canal.

Q. Professor, please explain that chart No. 13 and what the lines and figures on it mean?

A. These curves represent comparison of the chemical character of the two canals at Bridgeport and at Lockport.

Q. Now where is Bridgeport?

A. Bridgeport is the point located—

Q. It is in the City of Chicago, isn't it?

A. Yes, in the City of Chicago on the south fork of the south branch of the Chicago River.

Q. Isn't in only on the south branch?

A. It is on the south fork of the south branch of the Chicago River. There are two branches, the north branch
2066 and the south branch and the south fork runs into the
south branch at Bridgeport.

Q. Did you locate it on the south branch?

A. On the south fork of the south branch, that is what I meant to say.

Q. Now, where is Lockport? Just locate that. Don't talk about "those two points."

A. Lockport is 29 miles from Bridgeport. The western end of the Drainage Canal is at Lockport.

Q. Where it joins the Desplaines River?

A. Yes, and the Illinois and Michigan Canal runs through Lockport and crosses at Lockport—runs through Lockport and crosses the Desplaines River at Joliet.

Q. Five or seven miles or four miles below?

A. Yes, and then proceeds on its route to LaSalle, Illinois.

Q. Well, now, go on and explain the lines and curves on your map and what they mean.

A. We have here curves representing nitrogen as free ammonia in the Illinois and Michigan Canal. You can see from the great variation in the amounts of free ammonias running—

Q. Well, Professor, you didn't explain what the different colors meant?

A. The green color, or this top curve represents the Illinois and Michigan Canal at Lockport. The red color, or
2067 the red line represents the Illinois and Michigan Canal at Bridgeport.

What I wanted to show by these curves is the remarkable fluctuations in the amount of free ammonia in that canal, showing its fermentative character?

Q. Which canal?

A. In the Illinois and Michigan Canal, as compared with the Drainage Canal, the Drainage Canal being represented by the curves, the yellow line representing the Drainage Canal at Bridgeport and the dark line representing the Drainage Canal at Lockport.

We notice that the very much higher free ammonias in the Illinois and Michigan Canal as compared with the free ammonias in the Drainage Canal, while high in both canals—for instance. the Drainage Canal here at Bridgeport and the Drainage Canal at Lockport showing free ammonias above one part per million in the form of nitrogen as free ammonia, that is high free ammonia, stamp that water as sewage, but the ammonias in the Illinois and Michigan Canal are very much higher, showing that the an-aerobic bacteria have performed their work in the old Illinois and Michigan Canal much more effectively than in
2068 the Drainage Canal. The sewage in the Drainage Canal
as it reaches Lockport does not show very much improvement during its route from Bridgeport to Lockport. It demonstrates that the facultative an-aerobic bacteria do not work so effectively in the main drainage canal as they do in the Illinois and Michigan Canal. The sewage from the Drainage Canal is in a much more retarded state of purification.

MR. WOERNER: In a much cruder state?

A. Yes, in a much cruder state, and it is very much less purified in its initial stage of purification at Lockport than the Illinois and Michigan Canal sewage when it reaches Lockport.

Q. Now, Professor, what does chart No. 14 represent?

A. Chart No. 14 represents the comparison of results at Joliet and at Peoria, Ill.

Q. Results of what?

A. Results of analyses of samples of water collected during the months of October and November, 1901.

The green line represents the Desplaines River at Joliet; the yellow line represents the Illinois River at LaSalle. The dark line represents the Illinois River three miles above Peoria.

2069 Q. Well, you mean it represents the water in the river?

A. Yes sir. The very high results of free ammonia found in the water at Joliet are reduced somewhat by the time the water reaches Peoria. In other words, the initial process of purification has been materially facilitated during the transit of the water in the Illinois River from Joliet to LaSalle and Peoria.

This map will also show that the nitrites found in the Desplaines River at Joliet at that time, during those two months, were lower than the nitrites found at Peoria and at LaSalle. While this would indicate that the process of purification had advanced somewhat for the sewage running down the Illinois River between those points, the very high nitrites found at LaSalle and Peoria—at LaSalle representing a maximum of .164 parts per million and at Peoria a maximum of .154, I say they demonstrate that the process of purification of that sewage in the river coming from the main Drainage Canal principally, and from the Illinois and Michigan Canal, and from Joliet, that the process of purification has by no means been completed when the water reaches Peoria. The Illinois River in other words, is found to be highly sewage polluted by the time it reaches Peoria.

2070 How far is it to Peoria from Joliet?

A. 124 miles between Joliet and Peoria.

I wanted to say, while the ammonias are much lower at those points of LaSalle and Peoria, they are still quite high and, going with comparatively high chlorines and going with very high nitrites, that stamp the water of the Illinois River as it reaches Peoria as badly polluted water, during this entire investigation.

Another thing that is shown by this map is that the colder weather setting in during the month of November, the process of purification is considerably retarded. The result is that the ammonias go up at LaSalle and Peoria. In other words, the weather being colder the bacterial activity and purification of the river, principally in its preliminary stage, has not been great and it has been lessened by the colder weather. The result is higher ammonia and lower nitrites at Peoria and LaSalle.

ATTORNEY GENERAL CROW: What does this chart No. 15 represent?

A. This represents a comparison of results of the chemical analyses of samples collected during this period from October 1st to November 30th, 1901, from the Illinois River at the
2071 point of Beardstown, Peoria, Kingston, Pekin and Grafton.

. If we take the free ammonias here we will notice that as I said, with the approach of colder weather, with the approach of colder weather the process of purification is retarded in the Illinois River as well as every other river in such climates.

We see the ammonias going up correspondingly at all these points in great variation. I mean, as to the minimum and maximum results during the month of November.

I want to say here that in order to show the effect of this cold weather in retarding the purification of the sewage in the Illinois River that I have run the curve for Grafton up to December 18th. You will remember that I stated that we continued collection of daily samples of the Illinois River, Grafton, until December 18th and that at that time we obtained nitrogen in the form of free ammonia one part per million at that point.

What I want to demonstrate now is that the decrease and increase of pollution in the Illinois River produces corresponding fluctuation in the results. In increase of pollution, as you see hereby Beardstown, Peoria, Kingston, Pekin and Grafton, all go together. In other words, if a wave of polluted
2072 water proceeds down the Illinois River it increases pollution of the Illinois River correspondingly during its entire course.

Thus we see this big rise in nitrogen in the form of free ammonia at all those towns in the first week of November and continuing until the end of November. We see this increase of pollution followed by an increase of pollution at Grafton, running the free ammonia as ascertained by the analysis of a sample taken from the Illinois river at Grafton on December 18, 1901, as high as one part per million. This almost approached the pollution which we found at Grafton in the Illinois River soon after the opening of the Drainage Canal, that is, when it could reasonably be calculated that the first sewage flushed out of the Drainage Canal had come down the Illinois River.

As I said, there is no doubt that in colder weather the process of purification is much slower in all respects than it is during the warmer months, that is during the summer months, and we find that the last samples that we took from the Illinois River in December, 1901, show an enormous pollution of the Illinois River at its mouth, following an enormous increase in pollution at points up to Peoria. That is, when I speak of
2073 Peoria here, at a point three miles above Peoria, and since I have stated that the sewage of the Desplaines River pollutes the Illinois River above Peoria to such an extent as to characterize the Illinois River three miles above Peoria as a sewage polluted river. I say that this pollution found at Grafton on December 18th 1901, must be ascribed to pollution of Peoria, and the pollution of Peoria must be ascribed—at the point three miles above Peoria—must be ascribed to Pollution at Joliet, and the pollution at Joliet, as we have seen, partly being due to the Illinois and Michigan Canal, yet to large extent being due to sewage accessions from the Drainage Canal, we were justified, and I feel justified, in stating that the great pollution of the Illinois River during those two months found at Grafton, can be ascribed to a certain extent to the sewage accessions from the main Drainage Canal and to a large accession at that as demonstrated by the chart, in which I show the polluting effect of the main Drainage Canal on the comparatively pure Des Plaines River at the Ninth Street Bridge at Joliet above the point where the Joliet sewage and the Illinois and Michigan Canal sewage contaminate the Des Plaines River

I can demonstrate these corresponding fluctuations
2074 by the nitrites. You will see that the nitrites go up and down correspondingly at all these points in the Illinois River, again demonstrating what the ammonias show, that the pollution of the Illinois River at the point where the Des Plaines River enters the Illinois River is always followed by a pollution

at the mouth of the Illinois. The results show that this pollution corresponds in its increase and decrease in the Illinois River.

Q. Now, what is that Chart No. 16?

A. Chart No. 16 represents a comparison of the results obtained from the analyses of samples taken during the months of October and November daily from a point in the Mississippi River several miles above the mouth of the Illinois and from the Illinois River several miles above its mouth.

The blue line represents the Illinois River at Grafton. The red line represents the Mississippi River at Grafton.

If we take the ammonias—

Q. At Grafton or above Grafton?

A. The Illinois River at Grafton several miles above its mouth.

The red line represents the Mississippi River several miles
2075 above the mouth of the Illinois and the blue line represents the Illinois River several miles above its mouth.

You will see that the free ammonias and the chlorines and the nitrites during these two months are always higher in the Illinois River than they are in the Mississippi River at Alton.

The highest free ammonia found at Grafton during the last week of November was nitrogen in the form of free ammonia, .17 parts per million.

The lowest free ammonia found in the Illinois River during these two months represented .06 parts per million.

Until the week beginning the 15th of November there was not much difference between the free ammonias of the two rivers although the free ammonias in the Illinois River were always higher, but when the cold weather set in during the latter part of November, the free ammonia in the Illinois River at Grafton went steadily up, so that finally on the 18th of December it showed one part per million of nitrogen in the form of
2076 free ammonia.

Now, during that same time, samples were also taken from the Mississippi River at Grafton.

Now, I don't know whether I stated that fact in my statement today when I spoke of the samples being collected after November 30th, but samples were collected during that period also from the Mississippi River above Grafton.

Now, there is no corresponding rise to that extent shown in the Mississippi River, while there is an increase there in free ammonias, and you can see the effect of the colder weather, yet the Mississippi River must not have been sewage laden to any extent whereas the Illinois River being a river of great instability, because as we see, from the nitrites, the intermediate state of purification, as represented by the nitrites, is varying continuously. This demonstrates that the Illinois River was much more polluted at that time. and the unoxidized sewage because of the colder weather, along the entire river increasing in analytical figures from place to place as the water of the river proceeds toward the mouth. This increased sewage is represented by the high figures found at Grafton, Illinois.

In other words, if the Illinois River were not a heavily
2077 sewage laden river, the sewage would have been oxidized
much more readily and better, but being in large quantities the effect of the colder weather proportionately retarded the process of purification so much the more and there being evidently considerably less pollution in the Mississippi River the effect of the cold weather there was not so material because of the absence of pollution to any material extent.

Let us take the nitrites in the Mississippi River at Grafton. They amount to almost nothing. They show results, like the lowest result, .001 and .0005 which is a very inappreciable amount and very often carries a trace only, often being absent altogether.

ATTORNEY GENERAL HAMLIN: Is that the maximum or the minimum?

A. That is the minimum amount found in the Mississippi River at Grafton during those two periods.

The maximum runs up to .0015. In other words, there were no such variations as to nitrites in the Mississippi River during those two months, as were shown by this blue curve here in its great variation for the Illinois River results, showing nitrites as high at the beginning of the investigation as .06 parts per million.

2078 The fluctuations are shown by the minimum amount of
nitrites found in this river at that time, representing .033 parts per million.

I have not drawn out the curve for the nitrites at that point for the results obtained for the month of December during that period but I remember that the nitrites were low at that time, only demonstrating in this case that the purification process in the Illinois River had so much been retarded that it was largely in its primary state when reaching Grafton at that time during the cold weather, showing high free ammonias and low nitrites, so that the intermediate stage between the free ammonia and the nitrates had evidently not been reached for a large amount of that sewage. In other words, that the sewage was in a much more crude state when it reached Grafton in the Illinois River during the month of December than it was during the month of October and the early part of November before the cold weather set in.

When we look at the nitrates, the final stage of purification, to demonstrate to you how much purer and how much more stable the Mississippi River was at that time, we find very low
nitrites; we find low free ammonia and we find high nit-
2079 rates. In other words, the final stage in the process of
nitrification or oxidation of sewage had been reached in the water of the Mississippi River above Grafton to a much higher degree and in a much more advanced state than in the Illinois River where the nitrates are very low and the nitrites much higher than in the Mississippi River and the free ammonias higher and going up to the large figure of one part per million at the close of our investigation for that period.

Mr. WOERNER: Now, I want to ask you, how far is Grafton from St. Louis?

A. Grafton is 39 miles from the Intake.

Based upon the weekly averages calculated from the analytical results as also shown by the curves drawn on the charts presented, I am prepared to state that the same condition regarding the chemical character of the water along the route between Chicago and the mouth of the Illinois, as demonstrating pollution in the Illinois River by the main Drainage Canal and extending down to the mouth of the Illinois, were found to exist in October and November, 1901, and at the mouth of the Illinois up to December 18, 1901.

The principal conclusions therefore, which I have drawn

from the analytical results of our investigation of the
2080 waters of Lake Michigan, the main Drainage Canal, the
Des Plaines River and the Illinois River for the period of investigation in 1900 previously discussed, also applied to the second analytical survey of the water along the route from Chicago to the mouth of the Illinois.

It has been shown that the water as it leaves the Drainage Canal at Lockport to enter the Des Plaines River was on several days found to contain nitrogen in the form of free ammonia exceeding—

ATTORNEY GENERAL HAMLIN: I object to this sort of testimony as it is apparently merely argumentative.

A. (Continuing) exceeding 1.3 parts per million of water, nitrogen in the form of nitrites to the extent of .028 parts per million and chlorine 20 parts per million.

The pollution of the comparatively pure Des Plaines River by the sewage from the main Drainage Canal has been shown as also the pollution of the Illinois River by the sewage of the Des Plaines River.

At Peoria we find, three miles above Peoria, the Illinois River polluted to a high degree, as evidenced by the presence of nitrogen in the form of free ammonia to the extent of 1.348
parts per million; nitrogen in the form of nitrites .13 parts
2081 per million and chlorine 26 parts per million.

A water containing these three characteristic ingredients of sewage pollution to the extent represented by these figures, must be considered a badly polluted water. It demonstrates that the process of self purification of sewage from Chicago in the Illinois River had not been completed before it reaches Peoria and that the conditions as proven to exist in 1900 had not improved one year later.

The Illinois River at its mouth, Grafton, shows during this period from October 1st until November 30th, the presence of nitrogen in the form of free ammonia to the extent of .25 parts per million.

Nitrogen in the form of nitrites .07 parts per million.

Chlorine 26 parts per million.

The corresponding highest figure during this period for the Mississippi at a point several miles above the mouth of the Illinois were found to be:

Free ammonia .11 parts per million.

Nitrites .003 parts per million.

Chlorine 9.6 parts per million.

Comparing the results from these two points just dis-
2082 cussed we find again as was found in 1899 and 1900, that
the water from the Illinois River at its mouth, is decidedly more polluted than that from the Mississippi River above the junction of the two rivers.

The high free ammonia and nitrites, together with comparatively higher chlorines in the Illinois River as compared with the Mississippi River, characterize the Illinois River as a badly sewage polluted river during this period.

The high free ammonia found during the latter part of December at Grafton, representing the figure of one part per million of nitrogen in the form of free ammonia, proves conclusively that the pollution of the Illinois River along its route has not reached a stage when the river, or rather when the water of the river, arrives at Grafton, to justify any other conclusion than the one drawn from the investigation of 1900, that the Illinois River is so overcharged with sewage that it cannot purify itself by the time it reaches the mouth.

2083 Q. Now, what is this chart No. 17, which you have?

A. Chart No. 17 represents the results of the chemical analyses of the samples of water taken daily during the months of October and November, 1901, from a point several miles above the mouth of the Illinois River also from a point in the Mississippi River one mile above Alton and from a point in the Mississippi River above Hartford, Illinois and from a point in the Mississippi River at Grafton, several miles above the mouth of the Illinois.

The red line represents the Illinois River at Grafton.

The blue line represents the Mississippi River at Alton.

The yellow line represents the Mississippi River at Hartford.

The green line represents the Mississippi River at Grafton.

You will see that the free ammonia for the larger part of this period was lowest in the Mississippi River above the mouth of the Illinois. It was highest in the Illinois River several

miles above the mouth of the Illinois and that for most of the time the free ammonia at Alton and the free ammonia at Hartford were higher than the free ammonia in the Mis-
2084 sissippi River above Grafton, showing that the mixture must have taken place of the Mississippi and Illinois River after their junction resulting in an increase in the free ammonias at Alton and Hartford. That is for the larger part of the period. During one week the free ammonias were a little lower at Alton than they were in the Mississippi River above Grafton. They were also a little lower during the first week in October but only to a very small extent. For the remaining six weeks, the free ammonia was higher at Alton than it was in the Mississippi River at Grafton. The highest free ammonia found during this period in the Illinois River was .17; the lowest found in the Illinois River was .06. The highest free ammonia found in the Mississippi River at Alton during this period was .07—I wish to correct that, that is .08 and the lowest is .04. The figures obtained for Hartford were almost like those found at Alton. The variation was slight. The maximum variation amounting to .015, so that I need not quote those figures. I will say the maximum variation, showing that the free ammonias at Alton and the free ammonias at Hartford did not vary to any extent.

2085 Now, we will take the chlorines. We find the chlorines lowest for this period in the Mississippi River at Grafton and we find it highest in the Illinois River at Grafton running as high as twenty six parts per million. At all times during this period the figures for chlorine at Alton and Hartford were higher than those of the Mississippi River at Grafton and lower than the Illinois River at Grafton, demonstrating that the mixture of the two rivers had taken place in the channel from which the Alton and Hartford samples were collected, and demonstrating further with the increase in free ammonias and chlorines and also a corresponding increase in nitrites, an increased pollution of the Mississippi River from the higher polluted river water of the Illinois River.

The nitrites in the Mississippi River, above the mouth of the Illinois for this period were very low, as I have already stated for several weeks practically absent. The nitrites in the

Illinois River during this period were comparatively high. The nitrites obtained from the Illinois of the samples at Alton and Hartford during this period, always showed an intermediate figure between the always lower figure from the Mississippi River and always higher figure from the Illinois River, clearly demonstrating the mixture of those two rivers and as a
2086 result, an increased pollution of the Mississippi River
coming from the Illinois River.

Q. Now what is this chart No. 18?

A. Chart No. 18 represents the results of the chemical analyses of samples of water collected in the months of October and November daily in the year 1901 from the Mississippi River at Hartford and at the Intakes of the St. Louis Water Works, Chain of Rocks and from the Missouri River at Fort Bellefontaine.

Q. Please explain what the lines and curves and colors mean on the chart?

A. The blue line represents the Mississippi River at Hartford.

The green line represents the Intake and the red line represents the Missouri River.

The highest chlorines during this period were found in the Missouri River.

The lowest chlorines were found in the Mississippi River at Hartford and the chlorines at the Intake represented during this entire period, an intermediate figure, between the high chlorines of the Missouri River and the low chlorines of the Mississippi River. This demonstrates that during this
2087 period a mixture of the waters of the Mississippi and Mis-
souri was taking place in the Mississippi River after the junction of the two and its effect could be shown in th[illegible]ver chlorines at the Intake.

Q. Lower than what?

A. Lower chlorines than in the Missouri River.

Q. And higher than where?

A. Higher than at Hartford. It would show the mixtures.

GENERAL HAMLIN: Where is Hartford?

A. One mile above the mouth of the Missouri River.

The free ammonias for the three points here are almost alike.

Q. Suppose you give the percentage that you have there?

A. What's that?

Q. Have you got your precentages?

A. No sir, I haven't got any precentages out in this chart at all, not in this fourth investigation.

Q. This is 1901?

A. Yes sir, 1901. It shows that the free ammonias during the months of October and November at these three points were not differing much; in fact at times the free ammonia of the Missouri River would be higher than the free ammonia of the Mississippi River and then again at times the free ammonia of the Mississippi River would be higher than the Missouri River. The variations are not great, in fact calculated 2088 out in figures the greatest variation between the Missouri River free ammonia and the Mississippi River free ammonia at Grafton, the amount would be .04 parts per million. If at this time, the nitrites of the Missouri River would be as high as those found in the Mississippi River at Hartford, or higher as was shown by the free ammonia, we could ascribe the higher free ammonia in the Missouri River to sewage pollution, but the nitrites are lower, and since the high chlorines in the Missouri River are not attributable to sewage pollution of the towns and cities on the upper Missouri but are proven to be due to the drainage of the Kaw River, which runs into the Missouri River at Kansas City, due to the drainage of the Kaw River through districts vast areas in Kansas of salt beds it is to be concluded that the sanitary character of the Missouri River was better during this period than that of the Mississippi River after it was joined by the Illinois River and increasingly polluted by the Illinois River.

If we take the figures for nitrites for this period we notice that the nitrites in the Missouri River at Fort Bellefontaine were low. They varied from .001, as the minimum, to .0065 the maximum.

MR. WOERNER: Where is that?

2089 A. That is the nitrites in the Missouri River, the maximum found during this period at Bellefontaine. The figures for the nitrites at the Intake Tower during this period are almost similar to those of the Missouri River.

GENERAL HAMLIN: What months were those figures for?

A. October and November 1901.

WILLIAM C. TEICHMANN.

Adjourned until 10 A. M., March 19, 1903.

2090 Southern Hotel, St. Louis, Mo., 10:00 A. M., Thursday, March 19th, 1903.

Present, the Commissioner and the same Counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN.

Resumed the stand for further direct-examination by General Crow and testified as follows:

Q. Doctor, what is chart No. 19? Explain the curves and lines on that Chart and what is shows.

A. Chart No. 19 shows the correspondence between the curves representing the chemical examination of the samples of water collected during the months of October and November daily in the year 1901 from the Mississippi River at the Intake tower at St. Louis Water Works, from the outlet chamber of the St. Louis Water Works for the water as it passes through the reservior. The average time allowed for the passage of this water through the reservoir amounts to two days, sometimes it is less and sometimes it is a trifle more, but the average is about two days that this water is in the reservoir. The water from the river that is pumped in enters the reservoir from 2091 one side and leaves the reservoir at the other side which allows practically two days for sedimentation in the reservoir.

Now, I want to demonstrate by this chart that there is a partial purification taking place in the reservoir. As I stated previously in discussing the analytical results of our investigation of 1900, the amount of sediment that remains in the reservoir is about 85 per cent, that is the average. Now, while the sediment remains in the reservoir to such a large extent the quantities of impurities are not reduced so much, they are reduced some but it is very small. So small that practically we can say that the amounts of free ammonias and chlorines found in the water at the Intakes and the amounts of chlorines and free ammonia found in the outlet of the reservoir, do not differ materially. As regards the nitrites, there is some oxidation taking place in the reservoir at times, but we will see that the nitrites for the month of October do not vary much in the reservoir. These nitrites found in the water as it enters the Intake and in the water as it leaves the reservoir and in the water as it is drawn from the tap in the hydrant in the City Chemist's office, show hardly any significant variation.

During the month of November there appears a slight difference in the nitrites between the water taken from the
2092 river at the intake tower and from the water drawn from
the tap. We find the maximum variation there amounting to .003 parts per million. Now, this is not a very large variation. The amount of nitrites there found at the intake at that time in the Mississippi River, the highest amounted to .006, and the lowest found amounted to .001, which shows a rise in the amount of nitrites during the month of November, but not of any great significance because as I stated, the variations here are between very low figures. What can be noticed on this chart as very significant of the river is the remarkable correspondence in the fluctuation of impurities at the intake tower, at the outlet of the reservoir and the tap in the City Chemist's office. In other words, whenever the impurities rise in quantities in the water from the Mississippi River at the intake, a rise in quantity of these impurities follows in the reservoir and follows in the water taken from the tap of the city water supply. Whenever the quantity of impurities decreases at the intake we notice a subsequent decrease in the outlet of the reservoir, and notice a subsequent decrease in the water taken from the tap at the City Chemist's office, and again as we notice during this period, the rise takes place and the quantity of impurities at the intake is again followed by a corresponding rise of impurities in
2093 the water as it leaves the reservoir and as it leaves the
tap of the hydrant in the City Chemist's office. What I said for free ammonia applies also to nitrites, as you can see from these curves and it applies to the chlorines and it applies, in a measure to the nitrates. Of course, the nitrification process going on in the reservoir, that is the change in the chemical

character of the water from free ammonia to nitrites and nitrates, continually goes on in the reservoir and we see accordingly lower nitrite results and lower nitrate results for the water taken from the outlet of the reservoir and tap as compared with the water entering the intake. That much must be admitted that the purification process goes on in the reservoirs, but as we will see from these figures the purification process is limited and there still remains considerable of the impurities unoxidized that leaves the reservoirs and passes through the mains and leaves the taps or hydrants in the city. As I said before, the most significant conclusion we can draw for the comparison of these results is that the fluctuation in the impurities is in the rise and fall of the degree of impurities. These fluctuations always correspond between these three points of collections, the intake, outlet and the tap. In other words, whenever an in-
2094 creased pollution of the water entering the intake is shown
it is followed by increased pollution of the water passing through the reservior and an increased pollution of the water leaving the city mains. I stated previously in my testimony that samples of water had been collected under my instructions by a collector. I believe it is E. A. Sluder, in the year 1901 during the months of November and December, from points in the Missouri River above the mouth of the Missouri. The sample was taken from the Missouri River above Omaha, Nebraska, in the channel of the river near the Nebraska shore, on November 13th.

Q. Above Omaha?

A. Above Omaha. The sample showed 1325 parts per million of total solids.

Nitrogen in the form of free ammonia, .062.
Nitrogen in the form of nitrites, .004.
Oxygen consumed from the raw water, 7.1.
Nitrogen in the form of nitrates, .18.
Chlorine, 10 parts per million.

Q. When you say raw water you mean natural water?

A. Unfiltered, yes sir, the natural water. We call that raw in distinction from the filtered water.

Q. Call it natural water?

A. Yes sir. The filtered water from this point showed

2095 oxygen consumed 2.2 parts per million, chlorine 10 parts per million.

On the same day a sample was taken 10 miles below Omaha at Belle View, Nebraska, one and a half miles below this town and 10 miles below Omaha. The sample was taken from the channel of the river.

The first sample I mentioned and the data of which I quoted, had been taken far enough above the City of Omaha so as to exclude the Omaha sewage which is discharged into the Missouri River.

The result of the analysis of the second sample taken at Belle View, Neb., on November 13th, was:

Total solids 1074 parts per million.

Nitrogen in the form of free ammonia .136 parts per million.

Nitrogen in the form of nitrites was found to be .006 parts per million.

Chlorine was found to be 11.5 parts per million.

The nitrogen in the form of nitrates found at Belle View amounted to .16 parts per million.

Another sample was taken from a point above Omaha in the channel of the Nebraska shore near the water works of Omaha on November 24, 1901:

The total solids found in the analysis of this sample amounted to 1290 parts per million.

2096 Nitrogen in the form of free ammonia, found in the sample collected on that day from this point, was .056 parts per million.

The nitrogen found in the form of nitrites in the sample of water collected from this point on that day amounted to .001 parts per million.

The nitrogen found in the form of nitrates at this point on that day amounted to .18 parts per million.

The oxygen consumed found in the sample collected on this day at that point amounted to .6 parts per million for the unfiltered natural water and 2.6 for the filtered water, parts per million.

Chlorine from this sample collected at this point on that day amounted to 11 parts per million.

On the same day, November 24th, a sample of water was also collected from the Missouri River 10 miles below Omaha, near Belle View, Nebraska. The sample of water was found to contain total solids to the extent of 1050 parts per million.

The nitrogen in the form of free ammonia found in the water at this point collected on that day, amounted to .126 parts per million.

The nitrogen in the form of nitrites found in the samples of water collected from this point on that day amounted to .0025.

2097 Nitrogen in the form of nitrates found in the sample of water collected on that day was found to be .14 parts per million. The oxygen consumed for the unfiltered sample on this day was found to be 6.2 parts per million and for the filtered water from this same sample the oxygen consumed was found to be 2.2 parts per million. The chlorine found in this sample was 11.5 parts per million.

These results show that the Missouri River, as it approached Omaha, Nebraska, on November 13th and November 24th was polluted as shown by the presence of free ammonia of nitrites and chlorine. However, the nitrites found on both days being very low, showing only .004 parts per million, on November 13th and .001 parts per million on November 24th, together with comparatively low free ammonia and chlorine, and demonstrating that the pollution cannot be designated as sewage pollution. The low nitrites on both days would have been higher and the nitrates considerably lower, if the character of the Missouri River water as it approached Omaha had been of an unstable character indicating fermentative processes in the river.

Q. Professor, do you mean by that statement that the condition of the water there did indicate active fermentation process?

A. No, I mean to say that it did not, that the low nitrites 2098 and the low nitrates show that in the process of purification there, the organic matters present in the river had undergone—that these processes of purification had in a large manner, been completed, that is the water is of stable character.

Q. Now let me ask you a question. When you used the term purification did you use that from a chemical standpoint or in an ordinary acceptation of the term, or did you mean to convey the idea of oxidation taking place?

A. Oxidation taking place and producing chemically this change, which is not to be understood as implying exactly a definition of purity of water in general. It is only to be understood as connected with the fermentative and oxidation processes taking place in polluted rivers. As the Missouri River proceeds along its route it approaches St. Joseph, Missouri.

GENERAL HAMLIN: Did you take any samples below Omaha?

A. Yes, I got two from Belle View, Nebraska.

Q. That is the place, is it?

A. Yes, that is the place about 10 miles below Omaha. Strictly speaking it is one and a half miles below Belle View, Nebraska.

As I say, as the river approaches St. Joseph, we took
2099 samples, or rather I had samples collected from the pump
house of the Water Works of the City of St. Joseph in the channel of the Missouri River on November 14, 1901, and on November 26, 1901, from the analysis of these samples as follows:

The sample collected on November 14th. This water was found to contain total solids to the extent of 1225 parts per million.

Nitrogen in the form of free ammonia, .076 parts per million.

Nitrogen in the form of nitrates .22 parts per million.

Oxygen consumed for the unfiltered water from that sample, 9 parts per million, and for the filtered water from this sample the oxygen consumed showed 2.5 parts per million.

The chlorine amounted to 12.5 parts per million.

On the same day, November 14, a sample of water was collected from a point in the Missouri River, 12 miles below St. Joseph. The point is located 2 miles above a town called Wathena, Kansas. The result of the analysis of this sample was:

Total solids 1150 per million.

2100 Nitrogen in the form of nitrites, .007 parts per million.

Nitrogen in the form of nitrates, .26 parts per million.

Oxygen consumed from the unfiltered water from this sample, 8.7 parts per million.

Oxygen consumed from the filtered water of this sample, 2.8 parts per million.

Chlorines, 7 parts per million.

On November 26th another sample of water was collected from the Missouri River at St. Joseph near the Water Works and on the 25th of November another sample was collected from the Missouri River at Wathena, Kansas, 12 miles below St. Joseph. The results of these analyses were as follows:

Of the sample collected November 26, at St. Joseph above the waterworks of the City of St. Joseph, the total solids amounted to 1135 parts per million.

The nitrogen in the form of free ammonia was found to be .08 parts per million.

Nitrogen in the form of nitrites was found to be .006 parts per million.

Nitrates were found to be .2 parts per million.

The oxygen consumed was 7.1 parts per million for the unfiltered water from this sample, and 1.8 parts per million for the filtered water from this sample. The chlorine amounted to 16 parts per million from this sample.

2101 On November 18, 1901, a sample of water was collected from the Missouri River at Kansas City, one-half mile above the waterworks.

Q. Is that above or below the city?

A. Well, that is above the city where the waterworks are located.

The result of the analyses of the water from this sample was total solids 1152 parts per million.

Free ammonia .07 parts per million.

Nitrogen in the form of nitrites .005 parts per million.

Nitrogen in the form of nitrates .026 parts per million.

Oxygen consumed for the unfiltered water from this sample 8.1 parts per million.

For the filtered water from this sample 2.5 parts per million.

Chlorine 24.2 parts per million.

A sample collected from the Missouri River on November 17, 1901, from a point 10 miles below Kansas City, showed an analytical result as follows:

Total solids 1290 parts per million.

Free ammonia .112 parts per million.

Nitrites .005 parts per million.

2102 Oxygen consumed for the unfiltered water from the sample 8.5 parts per million.

From the filtered water 2.7 parts per million

Chlorine 18 parts per million.

A sample was collected on November 17, 1901, from the Kaw River at Argentine, Kansas. It was on the same day that the sample was collected from below Kansas City on the Missouri River. The analytical results from this sample show:

Total solids 687 parts per million.

Nitrogen in the form of free ammonia, in the sample from the Kaw River is found to be .062 parts per million.

Nitrogen in the form of nitrites was found to be .004 parts per million.

Nitrogen in the form of nitrates was found to be .1 part per million.

Oxygen consumed was found to be for the water from the unfiltered sample 7.8 parts per million.

For the filtered water from this sample 4.1 parts per million.

Chlorine from this sample taken from the Kaw River at Argentine, Kansas, on November 17, 1900, was found to contain 89.8 parts per million.

2103 On November 28th another sample of water was collected from the Missouri River at Kansas City at the point where the waterworks of Kansas City are located. The amount of total solids found in the analytical results of this sample showed the figure of 1070 parts per million.

The free ammonia, and the nitrogen in the form of free ammonia, amounted to .116 parts per million.

Nitrogen in the form of nitrites was found to be .004 parts per million.

Nitrogen in the form of nitrates .24 parts per million.

Oxygen consumed showed 6.2 parts per million for the water from the unfiltered sample and 1.9 parts per million for the water from the filtered sample.

The chlorines found in this sample amounted to 16 parts per million.

On November 28th, a sample of water was also collected from the Missouri River 10 miles below Kansas City. The analysis showed the following result:

Total solids 1100 parts per million,

Nitrogen as free ammonia .13 parts per million,

Nitrogen as nitrites .004 parts per million,

Nitrogen as nitrates .24 parts per million,

2104 Oxygen consumed for the water from the unfiltered sample 6.7 parts per million,

Oxygen consumed for the water from the filtered sample 1.9 parts per million,

Chlorine 23 parts per million.

A sample of water collected from the Kaw River at Argentine, Kansas, on November 29, showed the following results in the analyses:

Total solids 650 parts per million.

Free ammonia .036 parts per million.

Nitrites, none.

Nitrates .04 parts per million.

Oxygen consumed for the unfiltered water of the sample, 5.9 parts per million.

And for the filtered water from the sample 3.4 parts per million.

Chlorine 109 parts per million.

I shall continue to read off this data and then, in expressing my conclusions on the results as found at Kansas City and the Kaw River and the Missouri above and below Kansas City, I mean to put that all in together. I will finish the data first.

Q. Get through as quickly as possible.

2105 A. On November 19, 1901, a sample of water was collected from the Missouri River at Jefferson City, one mile above Jefferson City.

Q. Did you say that was above or below the city?

A. Above the city, one mile above the waterworks of Jefferson City.

The analysis of this sample shows the following result:

Total solids 1295 parts per million.

Nitrogen in the form of free ammonia .094 parts per million.

Nitrogen as nitrites .005 parts per million.

Nitrogen as nitrates .36 parts per million.

Oxygen consumed 9.6 parts per million for the unfiltered water from this sample and 3.1 for the filtered water from this sample.

Chlorine 20 parts per million.

A sample of water collected on November 19th, 1901, at a point five miles below Jefferson City, showed the following results:

Total solids 1315 parts per million.

Nitrogen in the form of free ammonia .09.

Nitrogen as nitrites .006 parts per million.

Nitrogen as nitrates .3 parts per million.

2106 Oxygen consumed 7.4 parts.

Chlorine 21 parts per million.

That oxygen consumed 7.4 parts per million was for the unfiltered water from this sample and 2.3 parts per million for the filtered water from the sample.

On December 1st, 1901, samples of water were again collected from points above and below Jefferson City in the Missouri River as follows:

December 1st sample collected from the Missouri River above Jefferson City near the waterworks at Jefferson City. The result of the analysis of this sample showed:

Total solids 1055 parts per million.

Nitrogen in the form of free ammonia .136 parts per million.

Nitrogen in the form of nitrites .008 parts per million.

Nitrogen in the form of nitrates .28 parts per million.

Oxygen consumed 6.7 parts per million for the unfiltered water from the sample and 2.7 parts per million for the filtered water from the sample.

Chlorines 23 parts per million.

The result of the analysis of the sample take on this date from the Missouri River five miles below Jefferson City is as follows:

2107 1005 parts per million total solids.

Nitrogen as free ammonia .136 parts per million.

Nitrogen as nitrites .007 parts per million.

Nitrogen as nitrates .26 parts per million.

Oxygen consumed for the unfiltered water from the sample 6.6 parts per million.

For the filtered water from sample 2.2 parts per million.

Chlorine 24 parts per milion.

On November 20th, 1901, a sample of water was collected from the Missouri River one mile above Hermann, Missouri.

Q. Where is Hermann, how far from here?

A. I couldn't tell you exactly.

Q. About 125 miles by river, isn't it?

A. It is between Jefferson City and St. Louis, I couldn't tell you exactly.

Q. It is 85 miles by rail and 125 miles by river.

A. 125 miles from the mouth of the Missouri. The amount of total solids found on this day, or rather found in the sample of water collected on this date at this point, showed in the analysis as follows:

Total solids 1740 parts per million.

2108 Nitrogen in the form of free ammonia .09 parts per million.

Nitrogen in the form of nitrites .005 parts.

Nitrogen in the form of nitrates .36 parts per million.

Oxygen consumed from the water of the unfiltered sample, 9 parts per million.

From the filtered sample 23 parts per million.

Chlorines 9 parts per million.

A sample of water collected in the Missouri River on the same date, November 20, 1901, at a point three miles below Hermann showed the following results:

Total solids 1155 parts per million.

Free ammonia .09 parts per million.

Nitrogen in the form of nitrites .005 parts per million.

Nitrogen as nitrates .36 parts per million .

Oxygen consumed for the water in the unfiltered sample 5.5 parts per million.

And for the filtered water from the sample 2.4.

Chlorines 18.5 parts per million.

On December 1st a sample of water was collected from the Missouri River at a point one mile above Hermann, Mo.

The total solids found by the analysis of this water amounted to 950 parts per million.

2109 Nitrogen in the form of free ammonias .106 parts per million.

Nitrogen in the form of nitrites .0045 parts per million.

Nitrogen in the form of nitrates .28 parts per million.

Oxygen consumed 6.5 parts per million for the unfiltered water from the sample and for the filtered water from the sample 2 parts per million.

Chlorine showed 19 parts per million.

The sample of water collected from the Missouri River December 1, 1901, from a point 3 miles below Hermann, Mo., showed total solids 170 parts per million.

Nitrogen in the form of free ammonia .126 parts per million.

Nitrogen in the form of nitrites .004 parts per million.

Nitrogen in the form of nitrates .26 parts per million.

Oxygen consumed from the water of the unfiltered sample 6.4 parts per million, and

For the filtered water from this sample 3.1 parts per million.

The chlorine was lost in analysis.

The sample of water collected from the Missouri River on November 22, 1901, at a point half a mile above St. Charles showed the following results:

2110 Total solids 1101 per million.

Nitrogen in the form of free ammonia .0834 parts per million.

Nitrogen in the form of nitrites .004 parts per million.

Nitrogen in the form of nitrates .56 parts per million.

Oxygen consumed for the water from the unfiltered sample 9.1 parts per million and for the water from the filtered sample 2.6.

Chlorine 18.5 parts per million.

Sample of water collected in the Missouri River on Nov. 22, 1901, at a point one and a half miles below St. Charles showed the following results:

Total solids 1072 parts per million.

Free amonia .046 parts per million.

Nitrogen as nitrites .0035 parts per million.

Nitrogen as nitrates .62 parts per million.

Oxygen consumed for the unfiltered sample 9.5 parts per million.

For the filtered water from the sample 2.8 parts per million.

Chlorine 19 parts per million.

The sample of water collected in the Missouri River December 3rd, 1901, at a point half a mile above St. Charles, Mo.

2111 The total solids found in this sample by the analysis amounted to 950 parts per million.

Nitrogen as free ammonia .246 parts per million.

Nitrogen as nitrites .005 parts per million.

Nitrogen as nitrates .26 parts per million.

Oxygen consumed for the unfiltered sample 6.5 parts per million.

For the filtered water from the sample 2.2 parts per million.

Chlorine 23 parts per million.

Sample of water collected on the same day, December 3, 1901, from the Missouri River, from a point one mile and a halt below St. Charles, Mo., showed the following analytical results:

Total solids 940 parts per million.

Free ammonia .112 parts per million.

Nitrogen as nitrites .006 parts per million.

Nitrogen in the form of nitrates .24 parts per million.

Oxygen consumed for the unfiltered water from the sample 6.6.

For the filtered water from the sample 2.1 parts per million.

Chlorines 23 parts per million.

Adjourned until 2 p. m., Thursday, March 19, 1903.

2112 Southern Hotel, St. Louis, Missouri. 2:00 p. m., Thursday, March 19th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN resumed the stand for further direct examination, by Attorney-General Crow, and testified as follows:

Q. Now, doctor, what do those examinations show with reference to chlorines in the Missouri River?

A. They show that there is an accession of chlorines in the Missouri River at Kansas City from the Kaw, also called the Kansas River, a river which has a length of about 300 miles and drains through a number of counties in which large salt deposits have been located, as it is reported by the United States geological survey. In other words—

Q. Well, that is sufficient on that. Now, you have got another chart there, haven't you—another map?

Is the Missouri River a stable or an unstable stream chemically?

2113 A. The chemical analyses show that the Missouri River as analyzed from Omaha down to St. Louis, has a character of considerable stability. The results are pretty much uniform along the route, with the exception that the high chlorines coming from the Kaw river increase somewhat the amount of chlorine in the Missouri River between Kansas City and St. Louis.

Q. Now, you have one more chart there, haven't you?

A. No, I have not.

Q. Have you got the general averages that you spoke of yesterday and said you would get?

A. The analyses? Yes, sir, I have them.

Q. Well, get them, please?

A. The curves on the chart presented yesterday—

MR. TODD: What numbers?

A. Charts numbered from 11 to 19.

ATTORNEY-GENERAL CROW: Inclusive?

A. Inclusive, representing the analytical data for the investigation of 1901, from October 1st, until November 30th, showed weekly averages. They did not show the maximum and minimum results for each week, but presented the weekly average drawn from the weekly maxima and minima.

I now read from the official analytical record the maximum results, together with the averages.

2114 Q. Now, don't put those averages in again.

A. Well, I can read the maximum then on the free ammonia, the nitrites and the chlorines for those points represented yesterday.

Q. Yes, those three things.

A. Yes, that is all the maximum figure for each week and the minimum.

Q. Haven't you got those in already?

A. No, sir; they were not presented yesterday. It is only the average that was presented.

ATTORNEY-GENERAL HAMLIN: You didn't present the average in figures?

A. No, they were on the charts.

Q. But didn't you give the average figures from the chart?

A. Well, I quoted them, but only as far as I thought it was necessary to explain the curves on the charts.

ATTORNEY-GENERAL CROW: Now, in order to save time, why not have copies of these made and furnish to the stenographers instead of reading them?

A. Oh, I can get through this quickly, it won't take me long to enter them.

Q. It will take you two hours and a half, won't it?

A. Oh, no, you see I can glance over them quickly. You see I have not presented a table for the analytical data 2115 for 1901.

Q. Well, now give us the tables without any remarks about them just put that in?

A. The free ammonias, nitrites, nitrates, and chlorines.

Q. That is the order in which you have them?

A. Yes, sir.

Q. Now, give them to us just as you have them.

ATORNEY-GENERAL HAMLIN: Now, give us the place first.

A. Bridgeport, Drainage Canal.

Q. ATTORNEY-GENERAL HAMLIN: Now, the first column is the maximum?

A. Yes, sir. The figures I am presenting now are the maximum results obtained from the chemical analyses of samples of water collected during the months of October and November beginning with October 7th daily from the Drainage Canal at Bridgeport, Chicago.

I also give the average figures as calculated from the analytical data:

Four samples representing dates of collection from October 7th to October 10th, inclusive, show on October 9th the maximum amount of nitrogen in the form of free ammonia to the extent of 1.508 parts per million.

The average for those four days amounts to .938 parts per million of nitrogen in the form of free ammonia.

2116 · Q. Now, Professor, it seems to me that those things could be copied very much more readily. Now, it would only take the time of all these gentlemen and the Commissioner and yourself, and I think it would suit the other gentlemen much better, and I know it would me.

ATTORNEY-GENERAL HAMLIN: I would be perfectly willing to have it copied.

THE WITNESS: The data on these sheets represent the analytical results obtained from a chemical examination of samples of water collected from—shall I mention all the points?

Q. Oh, no.

A. From various points indicated upon the tables?

Q. Give them, the period of time.

A. Which samples were collected and the analyses of the same performed daily during the months of October and November, 1901.

Q. Now, that is enough. The table can be inserted here: (Table not subsequently furnished. F. S. B., Com'r.)

2117 Q. Now, go ahead, Professor?

A. The fifth period of investigation began on December 1, 1901, and continued to July 1, 1902.

As already stated yesterday during this period samples of water were collected above Chain of Rocks from two points only during this period, that is from the Illinois River several miles above the mouth of the Illinois River at Grafton. Daily samples were collected until December 18, 1901, and daily samples were collected from the Mississippi River a few miles above the mouth of the Illinois River from December 1 to December 14, 1901.

With the exception of these samples taken at Grafton from the two rivers—there were no samples collected from any point during this investigation above the Chain of Rocks, St. Louis, in the Mississippi River.

Five samples were collected daily during this investigation. Three from the Mississippi River at Chain of Rocks opposite the St. Louis Waterworks.

One sample from the Illinois shore.

One sample from the entrance to the Intake Tower.

One sample from the Missouri shore.

One sample from the outlet chamber of the St. Louis Waterworks.

2118 The fifth sample from the tap in the City Chemist's office, St. Louis.

I have shown in the curves on Chart No. 16 presented yesterday, the results of the analyses of the samples of water taken from the Ilinois and the Missisippi River at Grafton from December 1 until December 18. The results obtained from the analyses of the samples collected during this period from the Mississippi River at the Chain of Rocks, at the outlet screen of the waterworks, and the tap at the City Chemist's office, continued to prove the pollution of our water supply in constantly varying degrees, from the Mississippi River.

The free ammonia during this period frequently rose to very high figures as found in the water collected from the Illinois shore. The enormous rise in free ammonias in the water collected from the Illinois River a few miles above Grafton during the second and third week of December, 1901, was followed by an increase in the amount of free ammonia found in the samples taken from the Illinois shore and also by an increase in the amount of free ammonia found in the samples taken at the Intake Tower during the winter months, January, February and March, while the free ammonia found on the Missouri shore showed higher figures than during the summer months in
2119 1901 and 1902. The rise in the figures of free ammonias found in the samples taken from the Illinois shore of the Mississippi daily and from the samples taken at the Intake, was comparatively much higher. In other words, during those months the sanitary character of the Mississippi water running along the Illinois shore was very bad, and in a measure affected

the sanitary character injuriously of the water supply of St. Louis.

On March 13, 1902, the amount of free ammonia, or nitrogen in the form of free ammonia, found in the sample of water collected at the Chain of Rocks at a point close to the Illionis shore —I say nitrogen in the form of free ammonia on that day from this sample amounted to 1.014 parts per million. This amount of free ammonia must be considered excessively high for a river water.

During that week the average amount of nitrogen in the form of free ammonia found in the samples collected on the Illinois shore of the Mississippi River amounted to .839. Every day during that week the nitrogen in the form of free ammonia exceeded .544 parts per million and while the figure of 1.014 was not reached again since that time, during the remainder of the month, the free ammonia remains very high. The lowest free ammonia found in the sample from the Illinois shore during that month was .26; still a very high figure of ammonia and an evidence of considerable pollution. 2120

Now, during this month at the Illinois shore the nitrites ran very high.

On March 28, we found in a sample collected from the Illinois shore .046 parts per million of nitrogen in the form of nitrites.

The chlorine on that date amounted to 8 parts per million.

The amount of nitrates found on this occasion was high—two parts per million.

During this month of March, 1902, samples collected from the Missouri shore of the Mississippi River showed free ammonias invariably much lower than those found in the samples from the Illionis shore, while the highest free ammonia found in the sample from the Illinois shore during this month amounted to 1.014 parts per million of nitrogen in the form of free ammonia.

The highest amount of nitrogen in the form of free ammonia found in the water collected from the Missouri shore 0.192 parts per million.

The highest nitrites found in the water from the Missouri shore during this month was 2.024 parts per million, found on March 20th, March 23rd and March 30th.

2121 The highest chlorines found in the sample from the Missouri shore during the month of March, 1901, amounts to 27 parts per million. The lowest amounted to 10 parts per milion.

Now, when we take the samples from the intake during the month of March we find the highest free ammonia during this month showed .254 nitrogen in the form of free ammonia. The highest nitrites showing .028 parts per million. The highest chlorine for this month amounting to 25 parts per million and the lowest to 10 parts per million, demonstrating great variation in the amount of chlorine in the water at the Intake Tower. Variations that are quite frequent during the month as they are during the other months and the seasons because of the unstable character of the water entering the Intake Tower and the constantly varying mixtures of Mississippi and Missouri River water going into the intake due to the frequently varying volume of the water coming down the water sheds of the Missouri, the Illinois and the Mississippi River.

The results for the analyses of the samples of water collected during this period from the outlet screen and the tap of the City Chemist's office again shows the same fluctuations, corresponding fluctuations in the chemical character of the water at the Intake, reservoir and the tap.

2122 Whenever the samples taken at the Intake Tower showed an increased pollution, this increased pollution was noticeable in the results of samples of water taken and analyzed from the outlet screen, or outlet chamber rather and the tap in the City Chemist's office. In other words, during this entire period, the character of the river water entering our Intake materially affected the character of the water supply of St. Louis.

During the spring and summer months of 1902, owing to the warmer weather facilitating oxidation processes in the waters, the Mississippi River water, as it entered the Intake showed some improvement. It was not sufficient to change the general unsanitary character of that water. The analytical results for ammonia, nitrites and chlorines remained high enough during this entire period, (until the cessation of this investigation on July 1st, 1901, at the old City Chemist's office, number 1141 Market street), to condemn the water as unfit for drinking purposes in its natural state.

The investigation, as far as reported to the authorities, terminated on July 1st, in the laboratory of the City Chemist's office of the Health Department of St. Louis, because of the removal of the City Chemist's office to new quarters in the old City Hall.

After the equipment of the new laboratory in the new City Hall, had been completed the investigation was re-
2123 sumed on October 1st and continued until January 1st, 1903, as follows:

Three samples were collected from the Mississippi River at the Chain of Rocks, one close to the Illinois shore, the other close to the Missouri shore and the third one at the Intake.

Daily samples were also taken during this period from the outlet chamber of the St. Louis Waterworks, and from the tap in the new quarters of the City Chemist's office.

The results of these analyses do not show any improvement in the sanitary quality of the water supply of St. Louis as compared with the results obtained from the previous investigations conducted in the City Chemist's office since August 23rd, 1899.

With the approach of the winter weather during the latter part of this investigation, the retarded oxidation characteristic of the winter season again resulted in an increase of the amount of free ammonia and nitrites found in the samples collected from the Mississipi River at the Chain of Rocks as well as from the outlet screen and the tap in the City Chemist's office.

Now, do you want me to give my final conclusions?

Q. Well, you have got another chart there, haven't you?

2124 A. No, I have not. What I wanted to read was from the official analytical data, those columns on the ammonias in March, 1903.

Q. Now, Professor, are you acquainted with the character of the Lake Michigan Water in front of the City of Chicago, in Lake Michigan, as to whether or not it is sanitary?

A. Yes, sir. I consider the Lake Michigan Water as it enters the Chicago River, polluted. It is not a pure water.

Q. Now, from your examination of these streams can you state whether or not the waters of the Drainage Canal pollute the Des Plaines river?

A. It is my opinion that they do.

Q. Can you state whether or not the Illinois River is polluted by the Drainage Canal?

A. Well, it is polluted by the Des Plaines river. You mean the Des Plaines river, do you?

Q. No, I am asking you if it is polluted by the Drainage Canal?

A. Well, indirectly, yes. The Drainage Canal doesn't connect directly with the Illinois River.

Q. I know that.

A. Yes, sir; indirectly, through the Des Plaines River.

Q. Can you state from your examination of these waters 2125 that the water coming into the intake of the St. Louis Waterworks now is less wholesome or less pure and less fit for sanitary use and domestic use than it was before the opening of the canal?

A. I think it is.

Q. I mean the Drainage Canal?

A. Yes, sir.

Q. Do you recognize as a chemist in analyzing water any difference between daily and weekly analyses in the results obtained chemically?

A. I do.

Q. What is the difference?

A. The most accurate results analytically are obtained from samples collected daily.

Q. Are you acquainted with the English Rivers Pollution Commission?

A. Yes, sir.

Q. Are you acquainted in a general way with the results of their work from a chemical standpoint and sanitary standpoint as to its effect upon sanitary water?

A. The English Rivers Pollution Commission was created in 1866 by the British Government for the purpose of investigating the question of the pollution by sewage from cities 2126 of the rivers in Great Britain. The investigations cover a period of eight years. During this period six reports were published. It was perhaps the most comprehensive investigation of the kind ever attempted until then and while a variety of opinions have been expressed as to the conclusions to be drawn from these reports, the predominating opinion after the publication of the reports—

ATTORNEY-GENERAL HAMLIN: I object to any opinion given by the English Commission or any statement as to what those reports contain on the ground, first that the reports would be the best evidence; second, that the evidence is not relative to the issues here.

MR. TODD: The Sanitary District joins in the same objection with the State.

ATTORNEY-GENERAL CROW: Go ahead.

A. The predominating opinion among sanitarians has been that the pollution of streams by sewage from cities and towns located on the banks of these rivers should be prevented by legislation, because the investigations conducted by the commission resulted in establishing the fact that pollution of streams by sewage of towns and cities in England was being carried on to an extent rendering the streams unfit for drinking purposes.

2127 ATTORNEY-GENERAL HAMLIN: I move to exclude all of the answer to the last question for the same reasons that are given in the previous objection.

MR. TODD: The Sanitary District joins in the same motion.

ATTORNEY-GENERAL CROW: Now, are you acquainted with the fact as to whether or not they have a septic tank system in Kansas City, Mo., for a large portion of their sewage?

A. The conditions of sewage disposal for the city of Kansas City are exceptional. It is a hilly city and the city grew up very fast and the sewerage system is very much behind the times. The development of the sewer system did not keep pace with the growth of the population and as a result to-day only 60 per cent. of the sewage of Kansas City goes into the sewers and drains into the Missouri River.

There are as many as 4,000 cess pools in Kansas City into which the sewage of the city is placed and kept there for some time, until the tanks are filled up and the sewage is then disposed of in various ways, used for manuring purposes—some burn it up, and about one-fifteenth of this sewage eventually reaches indirectly, the Missouri River, but when it reaches the

Missouri River it is sewage far advanced in its purification or rather in its oxidation and has an entirely different char-
2128 acter than the fresh sewage run into the river from the sewers.

Q. Now, do you know the distance by river from here to Kansas City?

A. No, sir; I haven't got the data at hand just now.

Q. Now, from your chemical examination as heretofore detailed by you of the waters of the Missouri River and of the Mississippi River at the confluence of the two streams, will you please state, if you know the fact, which is the better for use for domestic purposes and which is the more sanitary drinking water?

A. The Missouri River.

Q. Now, can you state from your examinations of these waters which is the better water for drinking purposes, that in the Mississippi River above the mouth of the Illinois River or the waters of the Mississippi River below the mouth of the Illinois and prior to its junction with the Missouri?

A. The Mississippi River above the mouth of the Illinois.

Q. Now, can you state from your examination of the water in these rivers whether or not the water coming in January, 1900, and from that time on, into the Intake Tower of the St. Louis Waterworks, whether or not it has as a rule, been potable water?

A. It has not.

2129 Q. Now, are you familiar with the theories of Tidy and Letheby, and other English scientists with reference to the effect of sewage upon running streams?

A. Yes, sir.

Q. Well, can you state whether or not the water in sanitary science as applied to the problem of drinking water supplies for large cities agree with the opinions of Tidy and Letheby and other English scientists of later days?

A. The theory of Tidy and Letheby originally attracted much attention. It practically amounts to this, that sewage diluted in pure water at the ratio of one part of sewage to fifteen parts of water would purify itself after running a distance of about 10 or 12 miles. It was this very theory that in its application in England proved to be fallacious in many instances, that led to the creation of the Rivers Pollution Commission in England, to which you referred in a previous question. The result of this investigation was that a new theory practically supplanted the theory of Tidy and Letheby in England, and that is that there is no river in England long enough to purify itself. I consider Tidy and Letheby's theory from the facts ascertained by a careful study of the question of river pollution, as antiquated and overthrown by the experiences of many communities in England as well as in other countries. 2130

This theory of Tidy and Letheby was tested so to speak by investigations carried on in England on the rivers Irwell and Mersey by Frankland, a prominent chemist and sanitarian of England in the seventies, in the years between 1870 and 1880, I can't recollect just now what years.

The conclusions drawn by Frankland from these investigations were that sewage discharged into a river at the ratio of a dilution of 1 to 15 as recommended by Tidy and Letheby, instead of purifying itself after a run of from 10 to 12 miles, only two-thirds of the sewage would purify itself after running a distance of 168 miles.

Q. Now, have you got a record of the low stages of the Illinois River?

A. Yes, sir.

Q. Have you got the stages of the river that show the lowest stage recorded for that river between the mouth of the canal at Lockport and the mouth of the Illinois at Grafton?

A. For what year do you mean?

Q. For the years 1900, 1901 and 1902?

A. Now, do you want the stages after the opening of the Drainage Canal or before?

2131 Q. After.

A. After the opening of the Drainage Canal it was very low. In February 1900 the Illinois River at Grafton showed the highest stage, during the month of January, 1900. On January 21st when it showed 5.9 feet. It then began to fall steadily until February 3rd when it showed only 1 foot at Grafton. Then there began a rise steadily almost from day to day and within a week the stage was 7.3 feet.

It remained close to that figure, that is varying between 6.6 and 6.9 for the following week. In the third week in February the river took a sudden rise on the 21st. On the 20th the stage was 6.9, and on the following day it was 8.3 and it remained at 8 feet, and went up to 8.5 and in the following week began to fall again down to 7.4, 6.1 and at the end of the week was 5 feet.

During March it fell down to 4.8 and beginning with the 6th of March showed a big rise. It rose from the 5th to the 6th of March from 5.1 to 7 feet. The next day from 7 feet to 9.3. The following day from 9.3 to 10.3, and so on, from day to day it rose averaging about a foot until the 13th of March it reached 14.8 feet—or rather that was on March 13th, it 2132 reached 14.8. Next day, on March 14th, 16.1; then it rose on the 16th to 17.3. That was its highest during that month and from that day on it fell steadily, varying from one to one-half feet per day until it got down to 13 feet and in the following week it fell to 12.6 on the 29th and ended with 11.8 on the 31st. Then for the next month it didn't vary so much but remained pretty steady for the next week between 11.5—no. it did rise again some to 13.3, but in the following week it only varied from 13.6 to 12.3 and for the next weeks or for the remaining two weeks in March it varied between 11 feet and 12.7. That is for the first four months from January to April, 1900, the stages at Grafton, of the Illinois River at Grafton.

Q. Now, have you got the stages of the Missouri and the Mississippi Rivers at that time?

A. Yes. Do you want to take the Mississippi first?

Q. Yes, come right down the river.

A. The Mississippi above the mouth of the Illinois?

Q. Yes.

A. These are the stages recorded at Louisiana, a town situated on the Mississippi River above the mouth of the Illinois. I can't tell exactly how far it is from the mouth.

Q. Well, anyhow, it don't cut any figure, the distance.

2133 A. No, there would not be much variation between the stage at Louisiana and at the mouth.

Q. No?

A. I don't think it would materially affect the figures.

The Mississippi River at Louisiana, Mo., showed during the month of January, 1900, throughout a very low stage varying between 1 and 3. There was a period of very cold weather prevailing at that time and in the beginning of the month in the first week, the river was frozen over and again at the end of the month, so that would have to be taken into account in calculating the measurements. Hence, there are such low figures as .7, that means 7-10 of a foot. That is the way it is measured out, it goes by decimals, you see. You see, it was ice frozen over—

MR. JOHNS: 7-10 of a foot of water in the Mississippi River at Grafton?

A. No, no, that was in the Mississippi River at Louisiana.

ATTORNEY-GENERAL CROW: 7-10 above or below the low water stage?

A. I have the official records for Keokuk for the same period, and they show this distinctly, and it was on those days that the river was frozen that we got these very
2134 low stages of water, because the rest was ice. It is just
measuring the water under the ice. The stage of three feet was only reached once during that month, on January 19th, for the major part of the month the height of the river varied between one and two and one-half feet.

MR. TODD: Doctor, do you mean that the ice was frozen so that there was only seven-tenths of a foot of water from the ice to the bottom of the river?

A. Yes, you see it wasn't frozen solidly, that is the idea. That is the way they estimate it at the Weather Bureau. It has been explained that way. You see, it is simply the gauge of the river—the gauge of the water of the river.

ATTORNEY-GENERAL CROW: Explain what that 7-10 means?

A. It means, calculated on the gauge.

Q. Well, put it in the record. Explain it?

A. These estimates are based upon the regular gauge of the river as taken for the United States Weather Bureau.

During the month of February—I will call it the gauge hereafter, that is just what it is meant to be. The gauge was for the period of very cold weather prevailing and the river was frozen over for about twelve days. The gauge for the second and the third was again below one foot, that is a decimal. During the second week the river rose a litle 2135 and it went up as high as 2.9 feet. Then in the next week it went up to 3.8. And in the following week it showed some slight variation only from 3.4 to 4 feet, the highest reached during the month, and at the end of the mouth it fell somewhat to 1.5 feet. It remained low again for about a week in March when it rose again, as follows:

On March 8th, the gauge was 3.1 feet,
March 9th, 5 feet,
March 10th, 5.1 feet,
March 11th, 6.9 feet,
March 12th, 8.3 feet.
March 13th, 11 feet,
March 14th, 11.7 feet,
March 15th, 12 feet,
March 16th, 11.9 feet,
March 17th, 10.5 feet,

Then it fell again.

On the 18th the river fell again to 9.1 feet,
On the 19th, to 8.5 feet,
On the 20th, to 8 feet,
On the 21st, 8 feet,
On the 22nd, 8.2 feet,
On the 23rd, 7.6 feet,
On the 24th, 6.9 feet, and it fell steadily during the 2136 last week of March to 5.1 on the last day of March.

I didn't give the Grafton, Illinois River stages for April did I?

MR. TODD: You didn't give Grafton.

A. Yes, I gave Grafton, Illinois River up to April 1st I am sure, but I was asking whether I gave it after April 1st. I can't remember this minute.

Mr. Crow, do you want the gauges of the two rivers for the months of April, 1900?

ATTORNEY GENERAL CROW: Yes, if you have got them. Just give the averages, don't give it every day. Just give the minimum and maximum stages, say one a week and shorten it up.

A. The fall in the rivers, in the Illinois and Mississippi at those points continued until the 3rd of April when there was a corresponding rise again in both rivers to 8.7 in the Mississippi River and 13.6 in the Illinois River at Grafton, which was the maximum gauge for both rivers during that time.

They began to fall down to 5.9 for the Mississippi and 11 feet in the Illinois River during the next week and during the last week of April both rivers rose about a foot, reaching a maximum height during that week of 8.4 feet for the
2137 Mississippi River and 12.7 for the Illinois River. In
other words during this month the heights, the rises and falls in the two rivers were corresponding for the month of April.

Q. Now, are you acquainted with the character of the Drainage Canal, with the character of the water, the appearance of it after its opening in January 1900?

A. Yes sir.

Q. Well, what was the character of that water?

A. From the samples you see—do you say whether I was acquainted with the water of the Drainage Canal?

Q. Drainage Canal, yes sir.

A. In January 1900?

Q. Yes.

A. No sir.

Q. Are you acquainted with the appearance of the Chicago River and its different branches prior to the opening of the Drainage Canal in 1900?

A. No sir.

Q. Do you remember being up there and seeing the waters?

A. Yes, I have been to Chicago and I have seen the Chicago River; I had seen the Illinois and Michigan Canal,
2138 and I had seen the main Drainage Canal prior to the open-
ing of the latter and on various occasions prior to the opening of the Drainage Canal.

Q. What was the appearance of the Chicago River as to whether or not it was a clean looking stream or unclean?

A. You mean prior to the opening of the Drainage Canal.

Q. Yes prior to the opening of the Drainage Canal.

A. Well, most of the times when I was in the City of Chicago the Chicago River had the appearance of a dark colored sewer water, emitting offensive odors and gas bubbles.

Q. Well now what was the appearance of the Illinois and Michigan Canal, of the water in it?

A. The water in the Illinois and Michigan Canal had the appearance of sewage and it was also of a dark color and emitting offensive odors and gas bubbles.

Q. Do you know anything about the cost of the St. Louis Water Works?

A. I have never studied that question; I couldn't give you any figures.

WILLIAM C. TEICHMAN.

Adjourned till the following day 10:00 A. M., Friday, March 20, 1903.

2139 Southern Hotel, St. Louis, Mo., 10:00 A. M., Friday, March 20, 1903. Present, the Commissioner and same Counsel representing the respective parties .

DR. WILLIAM C. TEICHMANN

resumed the stand for further direct examination by Attorney General Crow, and testified as follows:

Q. Now, Dr. Teichmann, are you acquainted with what is known as the Pettenkofer theory of the effect of pollution of waters upon running streams?

A. Yes sir.

Q. What was that theory?

A. The theory was that sewage discharged into a river and diluted at the rate of one part of sewage to fifteen parts of water would purify itself after a run of fifteen miles, provided that the velocity of the river into which the sewage was being discharged, was at least about the velocity of the sewage and that this velocity was at all times three-fifths of one metre which is equal to about two feet and one inch per second; that would be the least velocity per second.

2140 JUDGE JOHNS: You mean three feet and three inches a metre?

A. No, it was .6 metres. That is six-tenths of a metre or three-fifths of a metre. That will be about equal to two feet and one inch and it would have to have, at least that velocity per second.

GENERAL CROW: Now when was that theory first advanced?

A. That theory was advanced some time in the seventies, between 1870 and 1880, I don't know exactly when. I cannot find anywhere what time but during that period.

Q. Well, does that theory maintain today among sanitary scientists in water supplies?

A. No sir. Do you want my explanation why?

Q. Yes, you can explain why.

A. The experiences of various communities in applying this ratio of dilution on sewage discharged in running rivers in Europe has been such as to demonstrate that the theory cannot be applied any more with success. One of the greatest difficulties in the country is that running streams in themselves are not pure.

The ratio of dilution is based upon a mixture with pure water and whenever the ratio is applied, of a mixture of sewage with polluted waters, it proves to be fallacious.

It is true that a number of scientists have declared in
2141 various instances and quoted in scientific publications that
the theory proved to be successful, but other investigators have shown that those investigations upon which these scientists based their conclusions were carried on in an inaccurate manner. For instance, it was proven that the velocity of the current differs, that is the velocity of the water running along the shore and the velocity of the water running in the channel, differ.

It was furthermore proven that the velocity of the water on the surface of the river differs from the velocity in the middle depth of the river. It has been shown that the velocity of a channel is greatest in the middle of the depth of the river. Some investigators claim that the greatest velocity occurs at the depth of six-tenths.

Now, in taking samples a great many of these investigators who agree with Pettenkofer evidently have made the mistake of taking samples from the surface. The character of the water, I will say on the surface of the river is different than the character of the water at the middle of the depth, that is oxidation processes are somewhat facilitated by light, and the top water in the channel would present a different chemical character accordingly than the water running at a certain depth, as I said before, half of the depth of the height of the river. Therefore, such investigators as Classen, who is a chemist and a water specialist of much distinction in Germany—I say such 2142 men as Classen and others challenged the correctness and reliability of the analytical results upon which many of the followers of the Pettenkofer theory base their conclusions, that the Pettenkofer theory was correct. They proved contradictory data showing that this so-called self purification as announced by Pettenkofer, was in reality impossible, because, first of all as I have said, many of the samples were taken from the surface water and then again at the lowest velocity suspended organic matter would deposit at the bottom of the river not purified. This suspended matter having been deposited during the slow flow of the current at the bottom of the river, would at the next rainfall and heavy rise of the river, increasing the velocity, be carried up from the bottom of the river and then if that water would be analyzed it would show that the organic matter not yet oxidized coming from the sewage discharged into the river and supposed to have been purified at a flow of fifteen miles, was still there, it had not been purified and was then being swept with the increased velocity again from the bottom to the top and carried down the river, and analyses would show that the impurities that were supposed to have disap- 2143 peared, that were supposed to have been removed by the so-called self purification, had been removed from the surface only and had been deposited at the bottom of the river and turned up to the surface again as soon as the river was being flushed out by rain water coming up, so that the purification claimed by the Pettenkofer theory had not taken place. These investigations have been published in one of the greatest works that has been written on the pollution of waters, by an investigator of great prominence in Germany, who worked for many years on this book and brings in this publication all the researches pro and con on the subject of the so-called self purification for rivers.

Q. Who is that?

A. Julius Keonig and the title of this work is "Die Verunreinigung Der Gewasser," published in 1899.

Q. Well, what is the modern theory of this question of running water?

A. Well, according to the researches as described in this work a conclusion is justified that the oxidation of sewage discharged in the rivers depends so much upon various conditions and circumstances constantly varying and differing so materially as applied to various streams, that a hard and fast rule as to a ratio of dilution cannot be considered reliable any
2144 more.

Q. Now, have you got any data here showing the flow through the Chicago Canal, from an official source?

A. Yes sir.

Q. Where is it and what shape is it in?

A. I have an official tabulation.

Q. Where did it come from?

A. By courtesy of Mr. Todd, Counsel for the Sanitary District of Chicago, I have received the tabulations for the year 1900 and 1901, of the average daily and weekly rate of flow in cubic feet per minute of the water in the Illinois and Michigan Canal at Chicago, the main Drainage Canal at Chicago, the Chicago River at Chicago, the Desplaines River at Riverside, the Desplaines River at Joliet, including notes on water shed areas and weekly and quarterly summary of the above. This data having been compiled by Engineer E. L. Cooley, presumably under the directions of the Chief Enginer—

MR. TODD: Mr. Cooley is one of the assistant engineers of the Board.

A. Presumably under the directions of the Chief Engineer Isham Randolph.

GENERAL CROW: Do you know whether the Drainage Canal was closed during the greater part of September, 1900?

2145 A. Well, it was closed during the day time for several weeks excepting Sundays. The volume of water running over the dam at night is estimated and represented in the table there. There was some water coming in but in comparison to the regular flow it was a small flow. Do you want me to testify to that—this daily closing of the Drainage Canal at that time, in September, 1900, resulted in the reversion of the flow of the Chicago River back into the lake and as I have already testified, evidently resulted in an increase of the pollution of the water taken from the lake front, and as I also testified, I believe, but I am not sure about it, but think I did, that the Chicago River at that time, in the reversion of the flow back to the lake, again assumed this character which it had shown prior to the opening of the Drainage Canal, that is its color was darkened again and offensive odors and gas bubbles were noticeable along the route of the Chicago River during that period.

MR. TODD: Did you see this yourself?

A. Yes sir, I was in Chicago during that time. After the reopening of the Canal, with the regular average flow, the average flow at that time of the water was 300,000 cubic feet per minute, after that time of temporary closing in September, 1900 the accumulated accretions of Chicago sewage in the Drainage Canal being discharged into the Desplaines 2146 River and subsequently into the Illinois River, resulted in increased pollution of these rivers as traced along the route down to the mouth of the Illinois by the analyses of samples collected at points between Chicago and St. Louis at that time.

In other words, during that time there re-occurred what had happened soon after the opening of the main Drainage Canal, that, so to speak, a wave of pollution came down the Desplaines River from the Drainage Canal, down the Illinois River and into the Mississippi, increasing the pollution of the Mississippi River between Grafton and the Intake, and was followed by increased pollution of our water supply, as shown by the analytical data we obtained from the analyses of the samples collected along that route.

GENERAL CROW: Now, Doctor, after you have examined these waters chemically in the manner in which you describe, and having had experience in water analysis which you have, are you able to state whether or not, the sewage in the outfalls of the sewers in Chicago into the Drainage Canal reached by way of the Desplaines and Illinois River and the

Canal, and the Mississippi River to the intake of the St. Louis Water Works?

2147 A. Yes sir.

Q. Well, does that sewage come in there?

A. Yes sir.

Q. Now, having made these examinations of the water supply of this city prior to and since the opening of the Chicago Drainage Canal, are you able to state whether or not the water of St. Louis is more polluted now by reason of the opening of the Chicago Canal and the inflow of the sewage from the City of Chicago, than it was prior thereto?

A. I think it is.

WILLIAM C. TEICHMANN.

2148 THOMAS A. BUCKLAND

called as a witness on behalf of the Complainant, the State of Missouri, having been duly sworn by the Commissioner, was examined in chief by General Crow and testified as follows:

Q. Mr. Buckland, what is your occupation?

A. I am Assistant City Chemist of St. Louis.

Q. How long have you been occupying that position?

A. Well, about ten years.

Q. What chemical training have you had?

A. My chemical training, that is the college training, was in the St. Louis College of Pharmacy, from which I graduated in 1882.

Q. You have been following the business of chemist since that time.

A. Chemist and druggist, yes sir.

Q. Were you present in the City Chemist's office during the period of investigation and analyses of the waters of the Mississippi, the Missouri and the Illinois Rivers and the Illinois and Michigan Canal, the Lake Michigan water and the Drainage Canal water, beginning in 1899 and running up to January, 1903?

A. Yes sir.

Q. Now, what part in that work did you take?

2149 A. Well, at different times I took different parts. The largest part of the work I had was the ammonias and nitrites but at different times I made other determinations.

Q. Where did you work, in what place?

A. On the north-east corner of Twelfth and Market Streets.

Q. Well, what is that at the north-east corner of Market and Twelfth?

A. Well, it was at that time, the laboratory of the City Chemist. It has since been removed to the old City Hall.

Q. Well, it was in the laboratory of the City Chemist's office in this city where you performed your work?

A. Yes sir.

Q. Now, are you familiar in the first place with the methods of obtaining water samples?

A. Yes sir.

Q. Who delivered the samples at your office?

A. Well, various collectors employed for the purpose.

Q. Who employed them?

A. Well, at first they were employed by the Water Commissioner and later by the City Chemist under an Ordinance authorizing their employment.

Q. Now, was there any one in the laboratory whose business it was to receive these samples?

2150 A. Yes sir.

Q. Who was that?

A. During the first part of the investigation Dr. Teichmann and I used to attend to that.

Q. Now, what do you call the first part of the investigation, beginning in 1899?

A. No, I mean at the beginning of the large investigation when these men were employed by the Water Department, I think that was in January 1900. I haven't looked at those records. This is a matter of record and you will be able to tell from the records exactly.

Q. Have you got any memorandum of that showing when it was that you inspected these samples, when they were sent in?

A. I think so.

Q. Well, did you have any rule for the inspection of them?

A. Well, what do you mean by rule for the inspection of them?

Q. Well, how did they come to the office and what condition were they in when they came there?

A. Well, the bottles came capped with a piece of muslin and sealed with wax. The muslin was tied around with a string and the string sealed with wax and they were usually carried in the bottles which were brought in personally by the 2151 collectors, were usually brought in tin boxes made for the purpose. The samples received by express were contained in wooden boxes in the center of which was a tin box made for the purpose of holding ice and they were sealed. The box itself was also sealed according to my recollection.

Q. What time of year, if any, did you use ice to pack the bottles?

A. Well, in the hot weather we used ice as long as it was necessary to keep the samples cool.

Q. Now, suppose the bottles came there with the seals broken, were the samples used?

A. Well, I should think they wouldn't be, I don't think they were if the seal was broken. I should certainly have thrown one out if I had it.

Q. Now, when did they begin to send their samples from the City Laboratory over to Professor Keiser?

A. Well—

Q. Haven't you got some memorandum that will give those dates?

A. No sir, unless Dr. Teichmann has I have not.

Q. Well, do you know whether or not the samples were sent from the City Laboratory over to Professor Keiser?

A. Yes sir.

2152 Q. What condition were the samples in when they were received and in what condition were they when they left your office to go to Professor Keiser?

A. The samples were taken under the same conditions the others were taken and were sent as soon as possible up to Professor Keiser.

Q. Were they duplicate samples of what you analyzed?

A. They were duplicate samples of what we analyzed.

Q. The work you did in analyzing was a duplicate of the work Professor Keiser did?

A. Yes sir.

Q. Did you begin with them in January, 1900, in that investigation?

A. Yes sir.

Q. Did you continue that work there in the laboratory until it closed on January 1st, 1903?

A. Yes sir.

Q. Well, are you familiar with the practical methods that are used in analyzing water?

A. Yes sir.

Q. Well, what were the methods that you used, were they those that are usually and properly applied?

A. Yes, we attempted as a rule to follow the Massachusetts State Board of Health method in our examinations,
2153 but in each determination I can give you any information you want.

Q. I don't understand you?

A. I say our endeavor was to follow the methods of the Massachusetts Board of Health.

Q. Well, what was the last part of your sentence?

A. Well, I say in regard to any individual determination I can give you the information.

Q. I don't want any individual determination. Do you know how many analyses you made altogether?

A. Well there were about 8000 analyses made.

Q. Of water samples?

A. Yes sir.

Q. Well, did you have a man by the name of Taylor around your office, there, a colored man?

A. Yes sir.

Q. What capacity was he engaged in?

A. He was a janitor.

Q. What did he have to do with these samples?

A. Well, he put them in the ice chest and got the bottles ready for the collector.

Q. What did he do to get them ready?

A. He washed them out and placed them in boxes.

2154 Q. Is that all he did? Who sterilized the bottles?

A. Do you mean the bacteriological bottles?

Q. Yes, you furnished the bottles for the bacteriologist.

A. Yes, the bacteriological bottles were sterilized. I am not sure whether Taylor did any of that work or not. I think he possibly did some of it. The bacteriological work was under the control of Dr. Ravold and his assistants who attended to that.

Q. Well, what else did Taylor do, did he receive the bottles?

A. I think he did occasionally.

Q. Well who took the bottles over to Professor Keiser?

A. Well, they were sent to Professor Keiser in a wagon that was employed for the purpose of bringing samples down from the Water Works at the Chain of Rocks?

Q. You hadn't had any work or didn't do any work at any of these emergency laboratories that were had along on the route between here and Chicago?

A. No sir.

Q. You know nothing about that work?

A. No sir.

Q. Your knowledge is confined wholly then to the work that occured in the laboratory of the City of St. Louis?

A. Yes sir.

2155 Q. Now, was that work done under the personal supervision of Dr. Teichmann and his assistants?

A. Yes sir.

Q. Who else worked there with you during this period of time?

A. Well, there was quite an army of men.

Q. I mean as chemists or helpers and assistants?

A. They were Dr. L ttmer, Mr. Beneker, Mr. Miller, Mr. Goetz, Mr. Leavitt and Mr. Hammerer.

Q. They did different parts of the work?

A. Yes sir.

Q. Now, did you examine the results of the work there and tabulate it?

A. No sir.

Q. Who did that?

A. Well I think that was done by Dr. Teichmann, Mr. Miller and Mr. Goetz.

Q. You are still employed out there at the City Chemist's office?

A. Yes sir.

Q. Who made the entries of the data that was obtained
2156 as a result of these charts?

A. That is, you mean who made the entries in the books as the analyses were made?

Q. Yes.

A. Well, in most of the cases the determinations were made, and the entry made by the chemist who made the determination. And in case of the ammonia determination they were generally called off by the chemist who was reading the ammonias and copied into the book by one of the clerks.

Q. Well, it is the usual method followed in making these chemical analyses, employed by the men having different portions of the work?

A. Well, in such a large undertaking it certainly would be, yes sir.

CROSS-EXAMINATION BY MR. JOHNS.

Q. Where were the emergency laboratories connected with this work?

A. One was located at Grafton, one at Peoria and the other at Joliet, I think.

Q. What do you mean by an emergency laboratory?

2157 A. Well, they were temporary laboratories established for the purpose of making bacteriological tests.

Q. Well, were they also for the purpose of making chemical analyses?

A. No sir.

Q. No chemical analyses were made at any of these emergency laboratories?

A. Not to my knowledge. I am not certain. There is none of these results so far as I know, made at those laboratories. The emergency laboratories were under the control of Dr. Ravold, that being bacteriological work, and so far as I know, there was no chemical analysis made.

Q. As far as you know there was no chemical analysis made at any of these emergency laboratories?

A. No sir.

Q. If any were made at such laboratories they have been tabulated in the books and reports of the City Chemist in reference to this analysis that has been going on?

A. Well, I should suppose they would be, but I don't know anything about those tabulations.

Q. As I understand you, you do not personally know whether any chemical analyses were made at any of the emergency laboratories?

A. No sir, my impression was that there weren't any 2158 analyses made there.

Q. That is your best impression?

A. Yes sir.

THOS. A. BUCKLAND

No re-direct examination.

Adjourned until 2 P. M., March 20th.

2159 Southern Hotel, St. Louis, Mo., 2 p. m. Friday March 20, 1903. Continuation after recess.

Present, the Commissioner and same Counsel representing the respective parties.

HENRY DETTMER

called as a witness on behalf of the Complainant, being first duly sworn by the Commissioner, testified as follows:

DIRECT-EXAMINATION BY ATTORNEY GENERAL CROW.

Q. What is your name?

A. Henry Dettmer.

Q. Now, what is your profession?

A. Chemist.

Q. Where were you educated, Professor?

A. In Germany.

Q. Whereabouts?

A. I was educated—I graduated from the University of

Goettingen. I was educated in Germany and studied at the University of Goettingen in Prussia in 1880. Then I was two years and a half Instructor of Chemistry at the
2160 University of Bonn. In 1884 I came to this country and worked here for a large dairy company and then I became Professor of Chemistry at the College of Physicians and Surgeons, St. Louis.

Q. Professor of Chemistry?

A. I took the chair of Professor of Chemistry for four years in the St. Louis College of Physicians and Surgeons. Then I went to Germany and took a position there for four years at the Agricultural Experimental Station of Coeslin in Prussia.

In 1900 I came back and then I was engaged by Dr. Teichmann in this Drainage Canal, especially for the purpose of determining the total solids, and at the present time, I am first Assistant Chemist in our milk examination department in the City Chemist's office.

Q. And you have followed chemistry as a profession all your life, have you?

A. All my life, yes sir, all the time.

Q. You are familiar then with the modern practical methods of water analysis?

A. Yes sir.

Q. Now, when did you begin assisting Dr. Teichmann in the analyses of the water samples sent to your office?

A. I was engaged on January 24, 1900.

Q. Is that the date you began work?

A. Yes sir, I think that is the date, that is the 24th.

2161. Q. Now, where was your work done, at what place? The City Laboratory in the City Chemist's office?

A. Yes sir, the City Laboratory.

Q. In St. Louis, Mo?

A. Yes sir, in St. Louis, Mo.

Q. Now, what was the character of the water you worked on, that is how did the water come there that you worked on, did it come in barrels or how?

A. Oh, no, in bottles.

Q. In bottles?

A. Yes sir, sealed bottles.

Q. Sealed bottles?

A. Yes sir.

Q. Now, how long did you continue in that work. Have you continued in it ever since?

A. Yes sir, I worked on it from January 24, 1900, to December 1st.

Q. 1900?

A. 1900, and then the second time I worked from October 1, 1901, to December 1st.

Q. 1901?

A. 1901, the second time.

Q. And then you worked the third time?

2162 A. No.

Q. Only two periods?

A. Only two periods, yes.

Q. Now, what was the class of work that you did on these analyses?

A. To determine the residue or total solids after evaporation.

Q. Now, just tell me me how you did that, in what way?

A. Well, I worked—the amount of solids was determined in the unfiltered and filtered samples, 100 cubic centimeters of the sample was measured into a platinum dish of a capacity of about 1x150 cubic centimeters; evaporated on a large water bath to dryness. The dish was then placed in a drying oven and heated to a temperature of 110 degrees centigrade for one hour when it was transferred to a dessicator containing calcium chloride and cooled. The dish was weighed and the weight of total solids noted. Then the dish with contents was ignited over a Bunsen burner at a dull red heat and after cooling as before, weighed and the loss by ignition noted.

Q. Now who recorded the results of those analyses that you made?

A. We, ourselves, the chemists.

2163 Q. You did that?

A. Yes, I did that myself, figures and everything, yes.

Q. Now that is all of the chemical work that you did?

A. Yes sir.

Q. Now there were other men at work there that did other portions of these analyses?

A. Yes sir.

Q. Now, this work that you did was done under the supervision and direction of Dr. Teichmann?

A. Yes sir.

Q And those results as to total solids were a part of the analytical results that went to make the record of the analyses complete, of the water samples that were sent there?

A. That is right.

Q. Now, was the same method followed by you in the second period during which you examined these waters for the determination of total solids?

A. Exactly, yes sir.

Q. Now at what place in the analyses of water samples does the determination of total solids take its value?

A. Well, it shows, it gives us an idea of how much mineral matter there is in the water. Now, in the unfiltered sample and the filtered sample it is different. The unfiltered sample shows the mud, you know, the suspended matter, and if I make 2164 one sample of the unfiltered matter and then the filtered, the difference would give me the residue in suspension.

Q. Now will you please explain the difference between the suspended matter in water and the constituents or elements of water that are suspended chemically?

A. Well, in filtered water it is the ordinary—what we find in almost every water, spring water. Those are generally the chlorides of potassium and sodium calcium carbonate generally in the form of calcium bi-carbonate, calcium bi-sulphate, silica and magnesia.

Q. Well, now go ahead and finish the explanation as to the difference between suspended matter and the other substances in the water?

A. Now, in the unfiltered water what remains in the filter is nothing but suspended matter, generally clay and organic matter.

Q. Then, Doctor it is this, what you term suspended matter in the water, is matter that is put into the water and is not one of the chemical constituents thereof?

A. No, that is natural.

Q. Whenever you use the term suspended matter, it ap-

2165 plies then to some substance that is foreign to that water in its natural state?

A. Yes sir.

MR. WOERNER: And not salt?

A. Oh no.

ATTORNEY GENERAL CROW: Now then, Doctor, the record of these determinations of total solids were recorded in the office there at the time?

A. Yes, oh yes.

Q. Have you examined the records of those results as kept in the custody of Dr. Teichmann?

A. Yes sir.

Q. Do you know whether those results that he has, and the analytical charts recording the analyses of the water are correct as to the total solids?

A. Oh, yes.

Q. The method that you followed to determine these total solids is a practical and proper method to determine the total solids in water in the chemical analysis of the present day?

A. Yes sir.

2166 CROSS-EXAMINATION BY MR. JOHNS.

Q. What per cent of solids in suspension are in the water at the Intake Tower?

A. Well, I haven't got the records here, I don't know them by heart.

Q. Well give it from your best recollection?

A. I couldn't recollect that, I made so many and they were so different, you know. I have got everything in my book.

Q. Have you got in your mind the general average or general idea of the total amount in suspension.

A. No sir. Really, I don't know it by heart.

Q. Now, when you examined the unfiltered water you evaporated it to dryness?

A. Yes sir.

Q. And then you put that residue in a platinum dish?

A. Yes sir.

Q. And exposed it to the water bath?

A. Yes sir.

Q. For what purpose?

A. Well, to get rid of the water itself.

Q. Then it remained on the water bath how long?

2167 A. Well, that would depend on how much the residue was, sometimes several hours.

Q. Several hours?

A. Yes sir at least longer than two hours. In other words, so long until I was satisfied as a chemist that it was perfectly dry, all the water evaporated.

Q. After that you put it in an oven exposed to a Bunsen burner?

A. No, I put it in the oven for one hour at a temperature of 110 degrees centigrade.

Q. Well that heat was created by a Bunsen burner?

A. No, this was for the purpose you know, to satisfy us chemists that all the water what we took, chemical water, H_2O that is evaporated and then it was transferred to the dessicator and cooled down.

Q. And allowed to cool?

A. And allowed to cool and then weighed.

Q. How long did it remain in this oven?

A. For the second drying?

Q. Yes.

A. For the second drying, you mean in the dessicator?

Q. No. It was first exposed as being evaporated to dryness, it was exposed first to the water baths?

2168 A. Yes sir.

Q. And then, if I understand you, it was next exposed tc heat in some kind of an oven?

A. In the oven.

Q. And how long was it allowed to remain in that oven?

A. One hour.

Q. One hour?

A. Yes sir.

Q. Not fifteen minutes?

A. No.

Q. Never fifteen minutes?

A. No.

Q. Always one hour?

A. Yes sir.

Q. Was it weighed before it was put into the dessicator?

A. No sir.

Q. It was not weighed until after it had been in the dissicator?

A. Yes, until after it had been in the dessicator, yes.

Q. How long did it remain in the dessicator?

A. About fifteen minutes.

Q. Now, you put into that dessicator calcium chloride?

2169 A. Put in calcium chloride, yes sir.

Q For what purpose?

A. Well, calcium chloride is put into the dessicator to keep the air in it perfectly dry, to keep all the water out.

Q. To absorb all the moisture?

A. Yes sir. We used either calcium chloride—we had to transfer it from the oven to the balance.

Q. You didn't weigh this evaporated matter for the determination of solid matter, for the suspension, until after it had been in the dessicator?

A. Yes sir.

Q. And then that weight taken from the total weight of the water determined the matter in suspension?

A. Yes sir.

Q. Did you ever try and put it in the water baths or in the oven more than once?

A. Several times, yes sir.

Q. Was it your custom to put it in the oven and then take it out and put it in the dessicator and then take it out of the dissicator and put it back in the oven?

A. You mean, in other words, after I made the first weighing?

Q. Yes.

2170 A. I put it back and weighed it over again. Not always, no.

Q. How frequently?

A. Well, I couldn't tell.

Q. What was your general custom?

A. Just to weigh it once.

Q. Just to weigh it once?

A. Yes sir, because I made the first researches in my examination about those, upon this point, and my experience as an expert chemist taught me it is absolutely not necessary to put it back again out of the oven and weigh it. It is not necessary. It says, of course, in the books, to constantly weigh it. That is right, but it is not necessary.

Q. Now let me see if I understand you. Now, your general custom was to weigh it at once?

A. Yes, sir.

Q. Your general custom was to put it in the oven but once?

A. Yes, sir.

Q. And if you weighed it more than once or put it in the oven more than once, that was the exception and not the rule?

A. No.

Q. Well, no, you mean—

2171 A. Well, I mean—that is right. It is not the rule to put it back two times or three times because we found out by our researches that it was sufficient. We watched the temperature all the time. It was 110 degrees all the time.

Q. What is 110 degrees centigrade in terms of Fahrenheit? About 214 or 230 degrees?

A. Oh, it is many degrees above the boiling point.

Q. About 230 degrees or 240?

A. I think so, yes.

Q. Now, in determining the solids in solution, what did you do in the filtered water?

A. Well, you see—the same thing.

Q. You evaporated it again to dryness?

A. Evaporated it, yes; put it in the oven and after it was perfectly dry, in the water bath, we put it in an oven for one hour at 110 degrees centigrade and the difference between the filtered water and the unfiltred water gives us the matter in suspension.

Q. In solution?

A. In suspension; the difference between the solids of the filtered water and the unfiltered water gives us the matter in suspension.

Q. Yes. That is right. And the difference between the 2172 solids in solution and the solids in suspension?

A. Yes. Just to give you an example, we found in 600 samples of distilled water, that has no solids at all, but what spring water and river water contain naturally—those are the solids we call in solution. Now, our unfiltered water, the muddy water, you know that is the mud is nothing but suspended matter. If you get it settling it gets clear. Now you see, supposing I make a sample of total solids and in one unfiltered sample supposing I found 600 parts per million and I filtered this water through a filter—we filter it through paper—

ATTORNEY-GENERAL CROW: Swedish filtering paper?

A. Swedish filtering paper, yes, and we get it perfectly clear and everything remains in the filter, and then we found perhaps 200. Now, the difference from 200 to 600 is 400. Those 400 parts is the matter in suspension, generally clay or mud.

Q. MR. JOHNS: Now, in getting the solids in solution you pursue substantially the same process as in the solids in suspension?

A. Yes, sir.

Q. Through the unfiltered water?

2173 A. Yes, sir; the same process.

Q. How long did you expose the residue after evaporation of the filtered water, to the water bath?

A. The same, just the same like the other one.

Q. How long did you expose the residue, the same residue to heat in the oven?

A. The same.

Q. One hour?

A. The same, one hour.

Q. As to the solids in solution did you ever dry them more than once or put them in the oven more than once as a rule?

A. Not as a rule, no.

Q. You occasionally might have done it?

A. Yes, in the first time I made this research to satisfy myself that it was all right.

Q. Now, what per cent. of solids in solution would you say existed in this water as an average, to your best recollection?

A. Well, I could not recollect it at all as we made so many rivers and so many samples that really I couldn't give even the average of our Intake Tower except I get my record.

Q. Well, having done this so many times, have you not a general idea which you could give of the amount of solids 2174 in solution?

A. Well, I tell you. I didn't expect to be here and Dr. Teichmann just when I entered the office, told me to come right here to the court and so I wasn't prepared at all, otherwise I would get my notes. Excuse me for not answering that question.

Q. I mean merely in your mind in its present state, this moment, have you no idea of the amount of solids in solution as a general thing which you found. I don't want you to be accurate. I simply want your general idea as you now recollect it.

A. I couldn't answer that question now.

Q. Now, you made a record of the amount of solids that you found in suspension and also of the amount of solids which you found in solution?

A. Yes, sir.

Q. You put them in a book?

A. Yes, sir.

Q. You did that personally?

A. Yes, sir.

Q. What book?

A. Well, small note book.

Q. Now, then, were those records copied into still an- 2175 other book?

A. No, they were entered right away in our schedule, those long tables.

Q. In your tables?

A. Yes, sir.

Q. By whom?

A. Well, I couldn't tell. I gave my books to Dr. Teichmann and Dr. Teichmann attended to this.

Q. Dr. Teichmann put that down?

A. Yes, sir.

Q. Now, did you ever examine the record in this table and compare it with the record that you made yourself in your book?

A. Sometimes, yes, sir.

Q. How frequently?

A. Well, I couldn't tell.

Q. About how many times?

A. Well, I couldn't give a definite—anyhow more than twenty times or forty times.

Q. More than forty times?

A. Oh, sure, yes, because I looked it over all the time. I don't recollect who entered those things in our tables but I compared it with my original book.

2176 Q. As many as forty times?

A. Oh, I think so, yes, sir.

Q. Did you have a regular habit of doing that at any regular or certain time?

A. No, sir.

Q. You had no rule with reference to it whatever?

A. No.

Q. Then, have you any recollection of any particular date when you did so, examine the copy in the tables which was taken from your book?

A. No, I haven't got that.

Q. So, if any particular table of the originals, was presented to you here now, you could not identify it as having been examined by you and known to correspond with your record from your own personal examination?

A. No, I could not.

Q. Now, do you know whether or not copies of those tables made from your book were made for use in this testimony here?

A. Oh, yes.

Q. Well, did you ever examine the copies you have used in evidence here, with the originals as to the work on the solids which you did?

2177 A. I don't understand your question.

Q. If I understand you, the memoranda of data in your book—

A. Yes, sir.

Q. Was copied by some clerk of Dr. Teichmann on a table?

A. That is right.

Q. Now, that table so prepared, was again copied, was it not?

A. No, I think that is our original table.

Q. Is it here?

A. Oh, yes, they are here .

Q. Whether or not any particular original sheet in which your memoranda from your book was copied, if it were presented to you, you could not say you had examined it, you don't know?

A. No, not each sheet. It was impossible.

Q. So, that in reference to any particular sheet containing your determination of solids you could not now say that they were correctly copied from the book?

A. No, I could not say that, but I think they are checked up all right. We have got our original books there.

Q. Excuse me, but I am asking you of your own personal knowledge.

2178 A. That is right. No, I couldn't say that.

RE-DIRECT EXAMINATION, by Attorney-General Crow:

Q. You made the original entries in a little book, did you?

A. Oh, yes, then they were stored away.

Q. And then they were copied from the books on to these sheets?

A. Yes, sir.

Q. Now, the comparison that you spoke of that you had made so many times, were by comparing the book in which you had made the original entries, with these sheets?

A. It was all right, yes, sir.

Q. You did yourself?

A. Yes, sir; over forty times, at least.

Q. Did you make a habit of doing that to see that your work was correctly copied?

A. Oh, yes, from time to time, because the clerk was sitting here at the work and I looked there at my work, whether it was copied right or not; but of course, we were very busy, I couldn't look after every figure.

HY. DETTMER.

2179 SHERMAN LEAVITT called as a witness on behalf of the complainant, being first duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Attorney-General Crow:

Q. What is your name?
A. Sherman Leavitt.
Q. What is your occupation, Mr. Leavitt?
A. Chemist, Instructor at Washington University.
Q. Instructor in what?
A. Chemistry.
Q. Chemistry?
A. Yes, sir.
Q. How long have you occupied that position?
A. Since last November, the 24th of last November.
Q. Where did you study chemistry?
A. Washington University.
Q. Washington University?
A. Yes, sir.
Q. You have graduated, have you, in that science?
A: Yes, sir.

2180 Q. What practical experience have you had in chemistry?

A. Well, I was with the National Lead Company in Chicago for a year as chemist for them and then I was connected with Dr. Keiser as his assistant for about a year, a little over a year, and I worked on this work in the City Chemist's office under Dr. Dettmer.

Q. Talk a little louder.

A. I was down at the City Chemist's office under Dr. Dettmer and Dr. Teichmann for about four months, I believe. It was from the first of August, 1900, until the first of December, 1900.

Q. Now, what work did you do in the City Chemist's office?

A. I was under Dr. Dettmer, or rather I have worked on the total solids for Dr. Dettmer. I was under him.

Q. What time did you begin work there?
A. August 1st.
Q. What year?
A. 1900.
Q. How long did you work?
A. Until December 1st.

Q. December 1st, 1900?

A. Yes, sir.

Q. Did you work any more there?

2181 A. Not at the City Chemist's office.

Q. Did you work with Dr. Keiser afterwards?

A. Yes, I worked with Dr. Keiser in 1901.

Q. On samples of these waters?

A. Yes, sir.

Q. Well, you were an assistant to Dr. Dettmer, were you?

A. Yes, sir.

Q. You aided him in making his determinations for total solids?

A. Yes, sir.

Q. Are you familiar with the proper process to be had chemically for the determination of the total solids in water analyses?

A. Yes, sir, quite.

Q. Please state whether or not the usual and proper methods were employed there by Dr. Dettmer in making that determination?

A. Well, I think that was the method that was generally given by the best authorities.

Q. Where were these determinations made, in the city laboratory?

A. It was made in the City Chemist's office at 1141 Market street.

Q. Well, that is where the laboratory of the City

2182 Chemist's office is situated?

A. Yes, sir.

Q. Now, did you record the results of any determinations made by you?

A. Yes, sir; I recorded all of my results in my own book.

Q. In your own book?

A. Yes, sir.

Q. Then, what did you do with that book?

A. I turned it over to Dr. Dettmer and he then—he turned it over to Dr. Teichmann after seeing that it was all right.

Q. Now, was your work checked up and inspected by Dr. Dettmer?

A. Why, my work was entirely directly under his supervision. We worked almost side by side and I was under his authority and took all his directions. Whatever he told me to do I did, we worked exactly the same, at the same time.

Q. Now, you said you worked some with Dr. Keiser?

A. Yes, sir.

Q. In 1901.

A. 1901

Q. What was your part of the chemical work there?

A. Well, my part consisted—it was mere general work.
2183 I determined nitrites and nitrates and chlorides, and, well,
that was all I did, the main part of my work, nitrates, nitrites and chlorides.

Q. Now, in carrying on an extended examination of the waters of different streams, in a number of different streams, is it usual and necessary to have different chemists working on different portions of the work?

A. Yes, sir, it is; very often we have to do that. You see, with a large number of samples it is almost impossible for one man to cover any great amount of the work. There are so many things to be done, and it takes so much time.

Q. How many samples of water did you and Dr. Dettmer examine daily for the determination of total solids during the year 1901, from August to December?

A. In 1900, as I remember, we had 14. I think it was 14.

Q. Fourteen samples daily?

A. I think so, I am not positive about that.

Q. You were furnished samples every day, were you?

A. Yes, sir.

Q. Now, when you worked with Dr. Keiser, how many did you determine a day?

A. Well, Dr. Keiser and I did not do all of the samples that were taken there, we only did fourteen up there, whereas
I remember there were twenty-two taken altogether, some-
2184 wheres around there and we did fourteen of the principal
analyses out of the twenty-two.

Q. Well, fourteen samples daily was about as much as two men can handle for the determination of solids?

A. Determination of solids?

Q. Yes.

A. It was what we were doing. We did it very completely. We did it in the filtered and the unfiltered water and we did the loss on ignition and it made a great deal of work for two men, it kept two men busy, you see, we made a good many weighings in a day and if a man checked up his dishes faithfully, his platinum dishes, his changes in weight—we used it again and a great many weighings.

Q. And that was all detail work that had to be carried out?

A. Yes, sir.

Q. And the result thereof recorded as you pursued the investigation?

A. Yes, sir, recorded every day and each day's work dated. Anything that was out of order, it was recorded in a book. If anything didn't go just as it should I recorded it.

Q. You saw the samples as they came into the office?

A. Yes, sir.

Q. Were they all properly sealed?

A. As far as I saw them they were all properly sealed.

Q. Did you use any unsealed samples?

A. No, sir.

2185 Q. You had instructions against that?

A. When they were handed to me, you know, they had been opened, that is the men that did the nitrites— it was always customary to do the nitrites first, you know the oxidation is very rapid and they do the nitrites as soon as possible.

Q. That is the first thing that is done after the opening of the sample?

A. That was the first thing that was done after the opening of the sample.

Q. What did they do, take out a sample of the water?

A. Took out a sample for nitrites immediately.

Q. Now, then what was the next thing done with them?

A. It doesn't make any great difference, the ammonias should come next, the ammonias should come close to the nitrites, but the solids don't change, you know, the solids remain the same.

Q. And that would probably be done at the latter part of the work?

A. The solids could be done at leisure, almost any time.

Q. And the question of the length of time that the water had been kept would not interfere with the determination of the solids?

A. No, sir, not the total solids. It might be barely possible that some more might go into solution on standing

2186 any length of time. Of course, it is possible, you might have a little higher soluble solids as total solids, but the total solids of course, will be the same.

Q. What do you understand was the object of determining the total solids in water with reference to water analyses, what purpose does it show in the chemical examination of water?

A. Well, it merely shows the amount of matter which was held in solution. Of course, that shows more than the suspended matter. The suspended matter of course, is matter which can be filtered out and if it was removed of course, it would have nothing to do with the final quality of the water. That would largely settle out in a settling basin, but the dissolved solids, to my mind, show more than anything else, as far as solids are concerned, because they show the actual amount of solid matter which has been taken into solution.

Q. In other words, they show the natural chemical constituents of the water?

A. They show the natural chemical constituents of the water, that is the total chemical constituents.

CROSS-EXAMINATION, by Mr. Johns.

Q. You saw these packages with the seals upon them sometimes?

2187 A. Yes, sir.

Q. Where were they sealed?

A. Why, the seals were right on, as I remember it, they were on the side of the bottle, that is the stopper was always covered with a cloth and the seal as I remember, was on the side.

Q. Were the cloths tied down with a string?

A. Yes, I think it was tied with a string and then the seal placed on the string.

Q. On the string?

A. Yes, sir.

Q. Now, that seal was a wax seal?

A. Yes, sir; sealing wax.

Q. Now, did it have any designation on it, any stamp?

A. Well, I don't remember, I don't remember that fact.

Q. As to whether there was any designating mark on the seal?

A. No, sir; I haven't any recollection of that, because the samples as they came to me—that was merely what I noticed outside of my regular work.

Q. Now, the first thing done with water for analysis is the determination of the nitrites?

A. Yes, sir.

Q. And then the determination of free ammonia?

A. Free ammonia and albuminoid ammonia.

2188 Q. And then chlorines, and so forth, afterwards?

A. Chlorines and nitrates afterwards.

Q. You had a particular book in which you recorded the results of your labors?

A. Yes, sir.

Q. Dr. Dettmer had also a book in which he recorded his?

A. Yes, sir.

Q. You didn't work upon the same samples as Dr. Dettmer?

A. No, sir.

Q. But you worked side by side upon different samples?

A. Different samples.

Q. And then when you had your data reported in your book, and you delivered that to Dr. Dettmer?

A. Yes, sir; I delivered it to Dr. Dettmer.

Q. And then Mr. Dettmer's book and yours, do you understand that the results were noted onto tables or charts?

A. As I understand it, they were, yes, sir.

Q. Each sample that came in was numbered?

A. Yes, sir.

Q. When it came to you was it numbered?

A. Yes, sir.

Q. And then you put down in the book the number on the card on the sample?

A. The number on the card.

Q. And you put down the date, did you?

2189 A. The date of analysis, yes.

Q. You didn't put down the date that was upon the card, but the date of analysis, in your book?

A. Date of analysis, yes, sir; which was generally the same date.

Q. Generally the same day, I was about to ask you that?

A. Yes, as close after it as possible.

Q. Do you, as a rule—did you determine the solids very soon after the samples arrived in the office, in the laboratory?

A. Well, as soon as we could.

Q. What would prevent your doing it immediately?

A. Well, the rate of evaporation, the gas supplies had a great deal to do with it. Of course, some days we would not get as much gas supply as we would on others, after the evaporation, and then we were limited in our platinum ware. The platinum ware is very expensive and we were limited to a certain extent, limited in platinum ware, that is we could not keep up if extra samples were sent in as they were very often. We would get three or four days behind.

Q. Would there be some days in which you did not analyze for solids until 24 hours or 36 hours after samples arrived in the office?

A. There have been occasions when that has occurred, yes, sir.

Q. Now, your samples arrived at your place what time in the day?

2190 A. Well, as I remember it, it was about two o'clock in the afternoon.

Q. How long did it take you to conduct the analysis of one sample for solids?

A. Well, we didn't carry on one at a time, you know, we always carried on—

Q. You carried fourteen?

A. No, sir; we had eight dishes, we did it in sections. As I remember it, each man had eight dishes—that is, I am speaking entirely of my own work now. I had eight dishes and there were four samples of water. One dish was for the unfiltered sample and there was a corresponding dish for the filtered sample. That would make four samples at a time in a set.

Q. Well, when you commenced evaporation, for instance, of the unfiltered water, you put in four samples to be evaporated?

A. Yes, sir.

Q. And in the same way as to the filtered water?

A. Yes, sir.

Q. Now, did you evaporate the unfiltered and the filtered water at the same time?

A. I did.

Q. Did you dry the samples of the residue from the unfiltered water and the filtered water in the same water bath?

2191 A. Yes, sir.

Q. And at the same time?

A. At the same time, yes, sir.

Q. Did you then heat the samples of the residue of the unfiltered and the filtered water in the oven at the same time?

A. I did.

Q. How many samples would Dr. Dettmer have under his direction at the same time that you were operating on four?

A. The same number.

Q. Four?

A. Yes, sir.

Q. And the ones that he used were put in the water bath at the same time as yours?

A. They were put in his water bath and mine were put in my own.

Q. You each had separate water baths?

A. We each had separate water baths, yes, sir.

Q. Did you have separate ovens?

A. We had separate ovens, yes, sir.

Q. So that the four samples handled by each of you were dried in separate places?

A. Yes, sir.

Q. How long did you dry samples of residue in the water baths?

2192 A. One hour.

Q. How long did you dry them in the oven?

A. Oh, in the water bath?

Q. Yes?

A. I beg your pardon, it took longer than that as a rule. It took about an hour and a half anyway to dryness. As I say, that depends upon the gas supply and the rate of evaporation.

Q. Now, it varied according to your gas supply, and according to the rate of evaporation, of course?

A. Yes, sir.

Q. The dryness was determined by observation merely and knowledge of the dryness came from your experience and observation of it?

A. Certainly.

Q. Then after it was dried in the water bath, was it immediately taken to the oven ?

A. Yes, sir.

Q. And kept in the oven how long?

A. One hour.

Q. One hour?

A. Yes, sir.

Q. And then taken out and put in the dessicator?

A. Put in the dessicator.

2193 Q. And then when cool—how long, as a rule?

A. About fifteen minutes is the usual time allowed for dessicating.

Q. And then it was weighed?

A. Yes, sir.

Q. And after the weighing it was then heated to ignition?

A. It was.

Q. You never dried the samples twice in the water bath, or three times?

A. I don't exactly understand—

Q. You never exposed the residue of either filtered or unfiltered water to the drying process twice or three times?

A. Any of them?

Q. In the water baths?

A. Why, no, sir.

Q. Did you ever expose them or was it your custom to expose them twice or three times to drying in the oven?

A. No, sir.

Q. Not but once, as a rule?

A. Once, as a rule.

Q. And were they weighed between the water bath and the oven?

A. Between the water bath and the oven?

Q. Yes.

A. Oh, no, never.

2194 Q. Never?

A. Always after.

Q. Then they were never weighed but once?

A. They were weighed once after coming from the air bath, and then weighed once after ignition.

Q. Well, perhaps I misunderstood you. Do I understand you that the air bath is the oven?

A. Yes, sir. I didn't understand what you were getting at.

Q. Air bath is the proper term. They were weighed only once before ignition and that was after they came out of the water or air baths?

A. That is all.

Q. And then they were weighed after ignition again?

A. They were weighed again after ignition, yes, sir.

Q. And so the total solids both in suspension and solution were determined?

A. Yes, sir.

Q. Now, you put down in your book for your samples the total solids and matters in suspension, I presume?

A. First, in suspension.

Q. Second in solution?

A. Second in solution.

Q. Third after ignition, after heating to ignition?

A. Third after ignition. That was suspended, and then
2195 fourth after the ignition of the soluble matter.

Q. So that you made in your book each time, as to each sample, how many entries?

A. Well, there were four general entries there.

Q. Just for solid matter in suspension?

A. For solid matter in suspension.

Q. And solid matter in solution?

A. And solid matter in solution after ignition and soluble matter after ignition.

Q. The heating to ignition drives off everything but minerals, does it not, all vegetables?

A. It burns off any organic matter.

ATTORNEY-GENERAL CROW: Carbonaceous matter?

A. Carbonaceaus matter.

Q. MR. JOHNS: Now, these entries were made in your book in separate columns under separate headings?

A. Yes, sir; two pages were devoted to each sample. The left hand page was devoted to the solids in suspension and underneath it would be the ignition. Then on the right hand page would be the solids in solution and underneath that the ignition of the solids in solution.

Q. That would make two entries on each page?

A. That would make two entries on each page?

Q. Then you delivered your book to Dr. Dettmer?

A. Yes, sir.

2196 Q. And do you know as a matter of fact, what afterwards was done with the entries made by you?

A. Nothing that I know of personally except that the books were locked up in the safe afterwards. That is all I know about that.

Q. As to the copying into the table, you had nothing to do with that?

A. I had nothing to do with that, no responsibility about that.

Q. And you made no observations after that?

A. No, sir.

Q. Nor any comparisons?

A. Nor any comparisons.

Q. Was this copying done on the same day on which the entries were made on the tables, or do you know that?

A. I don't know.

A. Were these tables—if I understand you, you have not examined these tables as to correctness, as compared with your books?

A. No, sir, I have not been over them at all.

2197 RE-DIRECT EXAMINATION, by Attorney-General Crow.

Q. The work that was done by Professor Keiser and you on these samples in 1901, do you know where these samples came from?

A. In 1901?

Q. Yes.

A. Well, I don't know as I can remember them all right now.

Q. Well, but I don't mean places on the river. From what source did you receive the samples?

A. Well, they came from the City Chemist.

Q. What condition were they in when they came to your office?

A. They were still sealed in exactly the same way as they were when I worked on them there, just the same kind of a bottle.

Q. Now, was the proper process followed there for the determination of the chemical elements in the water?

A. Yes, sir.

Q. You worked, I believe you said, for nitrites and nitrates?

A. Nitrites, nitrates and chlorides.

Q. And that is all you had anything to do with?

2198 A. That is all I personally had anything to do with.

RE-CROSS-EXAMINATION, by Mr. Johns.

Q. You were with Dr. Keiser in 1901?

A. Yes, sir.

Q. I haven't a minute here of the time, what time were you there?

A. Well, it was October 1st, I think, to December 1st.

Q. What time in the day would the samples arrive at Dr. Keiser's office?

A. We received them there about 2 o'clock. I always received them when they came in. They would arrive about 2 o'clock as I remember.

Q. That is, they were brought to your place from the City Chemist's Office?

A. Yes, sir.

Q. And the samples were delivered to you?

A. Yes, sir, personally.

Q. Now, then, you saw the seals upon those, I presume?

A. Yes, sir, I did.

Q. Was there any designating mark upon those seals?

A. Well, I never noticed a mark, I never took the trouble to notice what was the designating mark on them. I merely noticed whether they were sealed or not.

2199 Q. Now did you then commence analyses for nitrites, nitrates and chlorides immediately?

A. I commenced the nitrites immediately, yes sir.

Q. Took nitrites immediately?

A. Took nitrites immediately always started with that immediately.

Q. How long would that operation take?

A. Well, it would take about—well, to draw the samples from the bottles, it would take perhaps fifteen minutes, and then the addition of reagents would take perhaps fifteen minutes more, and then they were allowed to stand for an hour and then they were filtered, and then allowed to stand, so that all together I suppose it didn't take over an hour.

Q. For each sample?

A. Yes, for the set, for the series, you know—for the fourteen.

Q. For the fourteen?

A. For the fourteen.

Q. If fourteen samples came in you commenced examination on the nitrites on the fourteen samples at once?

A. Nitrites were done immediately—we always made it a point to do the nitrites just as soon as possible.

Q. Now, did some other person work with you, side by side, in the determination of nitrites, or did you do that all
2200 yourself?

A. I did that entirely under Dr. Keiser's supervision; that is, he had general supervision over me.

Q. But you did the work on the fourteen samples?

A. I did the work on the fourteen samples.

Q. Of course that consisted of in each case of drawing a certain number of centimeters of the water?

A. Yes sir.

Q. And of putting in the reagents?

A. Yes sir.

Q. And of making the standard test tubes?

A. Yes sir.

Q. And the comparisons.

A. Yes sir.

Q. So that you could perform the work upon the nitrites during ordinary working hours?

A. Yes sir

Q. Before six o'clock, say?

A. Oh, yes sir.

Q. Well then, when did you commence on nitrates?

A. As soon after as I could,—as soon after the nitrites, as I could.

Q. Did you complete your work upon nitrites before you did any work upon the nitrates?

2201 A. No sir, while the nitrites were filtering, I then started my nitrates evaporating.

Q. So that the two processes went on simultaneously?

A. The two processes went on simultaneously—together, the nitrates of course being behind the nitrites in the readings.

Q. Now when did you commence work on the chlorides?

A. The chlorides I generally did the following morning.

Q. The following day?

A. Yes sir.

Q. But before you left the samples of that certain day the nitrites and the nitrates had been determined?

A. Had been determined, yes sir.

Q. What kind of tubes did you use for comparison?

A. The ordinary Nessler tube, 100 cubic centimeter Nessler tubes.

Q. Of what length, ten, twelve or fourteen inches?

A. I don't remember, I think they were about twelve inches.

Q. About twelve inches?

A. Yes sir.

Q. Both for the samples to be examined, and for the standard?

A. For the standard, yes sir.

Q. Those standards of course were built up after the sample under examination had assumed color?

2202 A. No sir, the standards were made up at the same time that I was preparing to put my reagents into the waters themselves, so that the reagents went into the standards at the same time that they went into the waters. They developed together.

Q. Of course in ascertained quantities?

A. Yes sir.

Q. And that work all could be done at the same time,—the reagents could be put into both tubes?

A. Yes that could be done at the same time.

Q. Then the determination of nitrites is by observation of the colors of the standard and the sample?

A. By comparison.

Q. By comparison?

A. Yes sir.

Q. How was that comparison made?

A. By the eye.

Q. Under what circumstances of observation?

A. Reflected light, from white surface.

Q. Upon a white surface?

A. Upon a white surface.

Q. What kind of a white surface—porcelain?

A. Either porcelain or paper.

Q. Or paper?

2203 A. Of course being under the same conditions. It wouldn't make any difference provided you had them both in the same condition, it was all right.

Q. If paper, what kind of paper was used ?

A. Well, writing paper.

Q. Ordinary writing paper?

A. Un-ruled writing paper.

Q. Now you made records of these examinations for nitrites, nitrates and chlorides?

A. Yes sir.

Q. In books?

A. In books.

Q. How many samples would you carry along at one time—fourteen?

A. Fourteen—kept the whole fourteen together.

Q. Well, as to nitrites, you did that?

A. I personally did nitrites, nitrates and chlorides.

Q. And you carried the fourteen samples along together?

A. I carried the fourteen samples along together.

Q. Now how many entries would be made in your book as to one particular sample, for nitrites?

A. Well, there would be an entry of the number of cubic centimeters of the standard nitrites solution which would match that water. There would be one entry for nitrites.

2204 Q. There would be one entry for nitrites?

A. Yes, of course the number, and one single entry.

Q. Number of the sample and one entry for nitrites, and that would be the constituents of the standard?

A. Yes sir.

Q. How many did you make for nitrates?

A. One entry for nitrates, with the number.

Q. In addition to the number?

A. Yes sir.

Q. And how many for chlorides?

A. There would be one—the same way.

Q. Were they all made in the same book?

A. No sir, there were three separate books.

Q. Each in a separate book?

A. Each in a separate book.

Q. And those entries when made by you were delivered to whom?

A. Dr. Keiser.

Q. What became of them after that?

A. Well, we worked over them after that, we worked together in making up our final records. Of course they have to be changed, you know, that is, as they are in the books, you have to compute them in different values, and parts per million.

2205 Q. Well now, was that entry made in your book, in your original book, the parts per million, after the calculations were made?

A. Yes sir.

Q. So as to each sample then there would be the number and the first entry as to nitrites and then the parts per million?

A. Then the parts per million.

Q. And then as to each sample in your book for instance there would be three entries?

A. There would be three final entries.

Q. There would be three final entries?

A. Yes sir.

Q. Now, after that was done your custody or supervision of the book ceased as to any particular entry?

A. They were drawn up on the charts of course, afterwards.

Q. Well, did you do that work?

A. Yes sir, I did.

Q. In putting these upon charts, did you do it entirely during the time you were there?

A. Yes sir.

Q. Both for yourself and any other person as to those three things,—you did it entirely on the charts?

A. I put that entirely down myself.

2206 Q. Those entries upon the charts were directly from your books?

A. Directly from my books.

Q. They were not entered into a larger book, much in the character of a ledger, and then copied from the ledger on the charts?

A. No sir, they went directly from the books onto the charts.

Q. And during the entire time that you were there you copied from your book directly upon the charts?

A. Yes sir.

Q. And what became of those charts afterwards, do you know?

A. I presume they are in Dr. Keiser's possession.

Q. Do you know whether or not a copy of that entry upon the charts was made upon another similar chart?

A. I do not.

Q. Do you know whether the originals of those charts were embodied in a report of Dr. Keiser to the City Chemist, and became a part of his report to the municipal government of St. Louis?

A. I do not. You see I left the city shortly after that work was done and what occurred after that, I have no knowledge of.

Q. Now as to nitrites and nitrates, the quantity in the sample is determined by observation of a standard tube made 2207 up with certain known quantities?

A. It is.

Q. And whether the color in the known standard test tube is the same as the color in the tubes, containing the sample, is a matter of correctness of eye-sight?

A. It is a matter of personal judgment, by eye-sight.

Q. Of personal judgment?

A. Yes sir.

Q. Placed side by side for observation, the two tubes?

A. Yes sir, under the same conditions.

Q. So that if a man was color-blind, the two tubes, if they were not the same, would look the same to him at any rate?

A. Well, that would depend entirely, I think, upon the degree of color-blindness.

Q. Now for instance, supposing a man who is unable to tell any shade of red from any shade of green—that happens to be my individual misfortune—could he be used to determine these colors by observation?

A. Well, I am not very well posted on that subject, but I think it is more the intensity of the degree of color rather than the color itself that counts. I don't know how a man would be fixed on that.

Q. Well if for instance your eyes were entirely correct and you had no defect as to color, no color-blindness, in 2208 order to determine the nitrites, your correct vision would show you by observation that the colors in the sample tube and the standard were the same?

A. Yes sir.

Q. And of the same intensity?

A. As near alike as possible.

Q. If a man had some slight color-blindness, do you know whether the two, if they appear exactly alike to the person of normal sight, whether the two would appear exactly alike to the man so affected?

A. I should think they would; I don't think it would have anything to do with that.

Q. Nothing to do with it?

A. I don't think so.

Q. So that whether a man was color-blind or not in any degree would not make any difference as to the observation of differences between the two tubes?

A. I should not think so. I don't see any reason why it should.

Q. It is purely a matter of observation?

A. I think so.

Q. And the more experienced the observer, the more likelihood of correctness in the results?

A. Yes sir.

2209 Q. And the less experience of the observer, the less the likelihood of correctness in the results?

A. I think so.

RE-RE-DIRECT EXAMINATION.

By Attorney General Crow.

Q. Those bottles were all tagged, were they not, when they came to your office—that is, tags were attached to them?

A. The number of the tag—The tag numbered and sealed, yes sir.

Q. Well, they had a tag also, didn't they?

A. The tag with the number on—the number and the place they were from, yes sir.

ADJOURNED until 10 o'clock A. M. following day, Saturday, March 21, 1903.

2210 Southern Hotel, St. Louis, Mo., 10:00 A. M. Saturday. March 21st, 1903. Present, the Commissioner and same Counsel representing the respective parties.

WILLIAM H. GOETZ,

a witness called on behalf of Complainant, the State of Missouri, after being duly sworn by the Commissioner, was examined in chief by General Crow and testified as follows:

Q. What is your name?

A. William H. Goetz.

Q. What is your address?

A. 5328 North Broadway.

Q. What is your occupation?

A. I am in the mechanical department of the City Water Works.

Q. What is your profession?

A. I am a civil engineer.

Q. Have you ever studied chemistry?

A. Yes sir.

Q. What education have you had in a chemical way?

A. I had two years at college and then my experience since.

Q. What kind of a college do you mean?

2211 A. The Cincinnati University.

Q. Is that a Chemical College?

A. Well, it has a complete chemical course.

Q. Whom did you study under there?

A. Professor Thomas H. Norton.

Q. What particular experience have you had as a chemist?

A. Well, I worked in the investigation at Cincinnati under Mr. George W. Fuller.

Q. What investigation?

A. The investigation there, prior to the installation of the new water works to determine the best system of filtration or the best method for purification of the water.

Q. Well, you worked on water analysis there?

A. Yes sir.

Q. What waters were you working in?

A. The Ohio River.

Q. How long a period of time did that cover?

A. Well, that covered four months about on that examination.

Q. What class of work were you doing there?

A. The chemical analysis of the water.

Q. Now, what other experience of water analysis have you had?

A. Well, after that investigation we didn't do any regular chemical work on water but samples were coming in 2212
there from time to time for about a year after that from different parts of the country.

Q. Well, you worked on that did you?

A. Yes sir.

Q. What other experience have you had on water analysis?

A. Just what I have had here in St. Louis.

Q. How long a period of time did that cover?

A. That was from about the 25th of February, 1900, to the 8th of January, 1901, and about the 6th of September, 1901, to the 8th of January, 1902.

Q. Whom did you work for here?

A. For Dr. Teichmann.

Q. What part of the work did you perform?

A. Well, I performed the analytical work, that is assisted in the analytical work, and working up the results afterwards, getting them tabulated and averaged in the form of charts.

Q. Now when did you first go to work for Dr. Teichmann?

A. I think it was either the 25th or 26th of February, 1900.

Q. How long did you work at that time?

A. I worked until the 8th of the following January, very nearly a year.

2213 Q. Now did you do nearly all your work in the City Laboratory here?

A. Yes sir.

Q. In the City Chemist's office?

A. Yes sir, I think it was all done there as near as I can remember.

Q. Did you do any particular branch of the work, as to solids or nitrites or nitrates?

A. We divided up the work and then traded around, I think during the course of the work, I did at one time or another, all the determinations except on the ammonias, I don't remember doing that.

Q. Now, after the result of the analysis was obtained, was there an estimate made any place of that result?

A. Yes, it was always copied in note books.

Q. Made at the time of the analysis?

A. Yes, right at the time.

Q. Well, was there any record made from those note books?

A. Those were afterwards collected and systematized into these large record sheets which were printed for the purpose and the analyses from the different points were collected and then averaged and then in the 1900 results there were also extra sheets made of weekly averages from the different points.

2214 Q. Did you have anything to do with that work?

A. Yes sir.

Q. What did you have to do with that work?

A. Well, Mr. Miller and myself practically had charge of that work, of getting those together, we had about four clerks that were helping us.

Q. Mr. Miller and you superintended the transcribing from the note books on to these analytical sheets the results of the analyses of the water samples?

A. Yes sir.

Q. Did you and Mr. Miller check all that work and see that it was correct?

A. Yes sir, we checked everything.

Q. Have you got those sheets here?

A. Yes sir.

Q. Just get them and see that they are the same sheets and if there is anything indicating that you did that work?

A. These are the same. These are the ones containing the weekly averages during 1900 for the different stages.

Q. Well, those sheets were made from the note books, were they?

A. Yes sir.

2215 Q. Then they were checked over to see if they were correct?

A. They were checked, yes sir.

Q. By whom?

A. They were checked by Mr. Miller and myself.

Q. Well, are those sheets you have there correct transcribings of the work from the notebooks.

A. Yes sir.

Q. Now do you know what waters these samples came from that these results here are the analyses of. Do you know where the waters were from that were analyzed?

A. Yes sir.

Q. Where were they from?

A. They were, a very few samples, from the lake and samples from the old Canal at Bridgeport and the Drainage Canal at Chicago and at Lockport, in the Desplaines River and the Canal and the mixture of the two, and the samples above Joliet and below Joliet and down at various stations along the Illinois River to Grafton and samples in the Mississippi and Illinois Rivers at Grafton.

Q. Well, the various locations from which the samples were taken are set down on these charts?

A. They are all marked on the charts, yes sir.

Q. Now did you have anything to do with the making of these maps on which the curves are?

2216 A. Yes sir.

Q. Who made those?

A. Well, Mr. Miller and myself made those.

Q. You made them under the supervision of Dr. Teichmann?

A. Yes sir.

Q. Now from what were those charts made?

A. Those were made directly from these weekly averages.

Q. And they are based on these figures and are the results of the analyses of these water samples?

A. Yes sir.

Q. Now what other periods besides from February, 1900, to January, 1901, did you work for Mr. Teichmann?

A. From about the 6th of September, 1901, until about the 8th of January, 1902.

Q. Now, what portion of the work did you do then?

A. The work was very similar to what had been done the previous year. We helped in the analytical work and we were collecting data afterwards and systematizing.

Q. Do you know where these samples came from you were working on?

A. Yes sir.

Q. Where?

A. Approximately they were about the same places as the others, with some changes.

2217 Q. Well, were the results transcribed in the books?

A. They were taken down in books, yes sir, transcribed to the sheets.

Q. Did you check those sheets, you and Mr. Miller?

A. Yes sir.

Q. You have those sheets here?

A. Yes sir, we have them here.

Q. Are these the sheets (referring to tables)?

A. Yes, those are the 1900 and 1901 sheets.

Q. Well, from checking and examining that you and Mr. Miller did and comparing those results with the data in the books, I will ask you are these sheets a correct record of the result of the analyses of these water samples?

A. Yes sir.

Q. Now, were there any maps and curves made from these?

A. Yes, we made curves similar to the ones we had made the previous year.

Q. And these curves on these maps were based on these figures?

A. Yes sir, on the weekly averages.

Q. Now, what other period did you work, if you did work any other period?

A. No sir, that was all.

2218

CROSS EXAMINATION

By Judge Johns.

Q. Of what college are you a graduate?

A. The Cincinnati University.

Q. When did you graduate there?

A. In 1897.

Q. You worked in the laboratory connected with that college in a course of chemistry?

A. Yes sir, two years.

Q. Was it during your under-graduate course that you assisted in the analysis of the water of the Ohio River?

A. No sir, it was afterwards.

Q. You afterwards did that?

A. Yes sir.

Q. How long were you connected or engaged regularly and continually in the analysis of waters at Cincinnati?

A. About four months.

Q. How long did you remain in Cincinnati after that?

A. I remained there a year after that.

Q. Were you in the laboratory continuously after that studying chemistry?

A. Yes, I was in the laboratory after that.

Q. Continuously after that year?

A. Yes sir.

2219 Q. Engaged in the general study of chemistry?

A. Yes, general work connected with that department.

Q. With what department?

A. With the laboratory which had been built for the purpose I have just stated, for the new water works they were building there.

Q. Well, under some officials of the City of Cincinnati?

A. Well, under Mr. George W. Fuller, who was employed by the City.

Q. And you worked in that laboratory continuously, a year?

A. Well Mr. Fuller was only there the first four months, then after he left I was there about a year afterwards under a man who had been the principal chemist while Mr. Fuller was there.

Q. Well, were you at that time a resident of St. Louis?

A. No sir.

Q. When did you become a resident of St. Louis?

A. I will have to ask you what you call becoming a resident?

Q. Coming here to live permanently.

A. The 25th of February, 1900.

Q. You went then directly into the laboratory of the City Chemist, Dr. Teichmann?

2220 A. Yes sir.

Q. What did you first do in the laboratory?

A. Well, as soon as we could get the things or work definitely outlined we took up the analysis of the samples that were coming in.

Q. Wasn't the laboratory organized and in full working order for the analyses of waters before the 25th of February, 1900?

A. Yes, I guess it was but being a number of new men at that time they had to increase the facilities.

Q. So some addittions were made to the laboratory at that time?

A. Yes sir.

Q. Were you engaged in making these additions before you commenced the work of analysis?

A. Well, I was indirectly interested in them but I had no supervision over them.

Q. Well, before the 25th of February had you anything to do with them?

A. No sir, nothing to do before the 25th of February.

Q. Now, when after the 25th of February did you actually commence as an assistant in the analyses of these waters?

A. Well, it wasn't over three or four days probably.

2221 Q. What did you first do?

A. Well, the first thing we did, or rather the first thing I did—

Q. Yes, you individually?

A. Was to make the chlorine determination on some samples which were at that time in the laboratory; some back samples in which all the other determinations had been made except the chlorines, I worked those up the first day.

Q. How old were those samples when you worked on them?

A. Those were samples which had been taken before I came there, there was comparatively few of them.

Q. How many?

A. I don't think over 100 of them.

Q. Do you know from what points they were?

A. They were taken from the same points as the samples which were taken later, only there were not so many stations of collection at that time.

Q. Now, take any one particular sample in which you determined the chlorines, can you tell how long it had been in the laboratory before this chlorine determination?

A. No sir, I couldn't say just how long.

Q. Did you do any other work in analysis than chlorines?

A. Yes sir.

2222 Q. What else?

A. Do you mean right here at the start?

Q. Yes.

A. We divided up that work, the different analyses, and each one of us took two or three of them approximately to make the work even. Then we would change about once a month but I don't remember just what analyses I had at first.

Q. Do you remember what you were next engaged in analyzing, what elements you looked after, after the chlorines?

A. I don't remember which ones.

Q. How many people were in that laboratory when you went there?

A. Dr. Teichmann, Mr. Buckland, Dr. Dettmer and a clerk. There were several others around there, I don't remember the names of them at present.

Q. How many people all together now, from the janitor up to Dr. Teichmann, including the whole force were in that laboratory while you were there?

A. When I came there first, do you mean?

Q. Yes.

A. Well, I don't remember distinctly, I should say somewhere from eight to nine.

2223 Q. Did you work at any time individually, on the solids in suspension?

A. I did for a short time, I think about two or three days was all I had.

Q. Did you work at any time in nitrites?

A. Yes.

Q. How long a time did you work on them?

A. Well I took about a month at a time, several times. I suppose two or three months all together, I don't know exactly.

Q. You changed around?

A. Yes sir.

Q. No one of the men or two men devoted their entire time and attention to the determination of any one particular element of pollution in water?

A. We did it by the month or so at a time.

Q. I mean during the entire period?

A. No sir, at least I didn't.

Q. So that your force were constantly shifting?

A. Well, the shifting principally was confined mostly to the three of us, Mr. Benneker, Mr. Miller and myself. I don't think there was any change amongst the others. Dr. Dettmer, for instance, devoted his time to solids during the entire investigation.

2224 Q. And Mr. Buckland, what did he do?

A. This shifting arrangement was merly between us three, Mr. Miller, Mr. Benneker and myself.

Q. What did Mr. Buckland do?

A. This shifting arrangement was merly between us three, Mr. Miller, Mr. Benneker and myself.

Q. What did Mr. Buckland do?

A. Well he is the Assistant City Chemist there, and had charge of the different parts of the work. I don't remember just exactly the schedule?

Q. What work did he actually perform himself?

A. Well, he had charge of the ammonia distillation for a part of the time. I couldn't say just exactly what his work was? My work was mostly in the adjoining room.

Q. Did you have any person there working with you, by your side, as a companion during this time?

A. In the nature of an assistant do you mean?

Q. Yes or companion. That is, did you work in teams?

A. No sir we worked singly.

Q. For instance, if a person would work at the determination of solids in suspension, he would have charge of a certain number of instruments to use for the evaporation of the water?

A. Yes sir.

2225 Q. And some other person would have charge of a certain number of others, of the flasks for evaporation?

A. Yes sir.

Q. But when you were doing the work, say nitrites for instance, who worked with you?

A. On those determinations?

Q. Yes on those determinations?

A. Nobody.

Q. You did that entirely?

A. I did that myself, yes sir.

Q. When you worked at the chlorines who worked with you?

A. No one.

Q. You did the work yourself?

A. Yes sir.

Q. And how many samples of the chlorines would you determine each day?

A. Why, that we—we determined the number of chlorines in the number of samples that were taken that day.

Q. Well, if there were fourteen samples that day, you determined the chlorines in them?

A. We did fourteen chlorine determinations.

Q. Now if the samples came in at two o'clock in the afternoon, or three o'clock, did you work on the chlorines for
2226 that day on those samples?

A. Worked upon all samples that were unpacked on that day. The samples which came in too late were kept packed in ice until the following day.

Q. Then if some were kept over until the following day, you worked on them until the arrival of the others the following day?

A. Sir?

Q. If some samples were kept over in ice, you worked upon them in the forenoon of the next day until the samples arrived for that day?

A. The samples began coming in early in the day, in the morning, and those samples we worked up that day.

Q. From what points did the samples come in, in the morning?

A. I am not familiar with the time of the arrival of the samples.

Q. Do you know that any did come in the morning of any day?

A. Yes sir, I do.

Q. Well, where from and who brought them and what time did they arrive?

A. I am not familiar with the schedule of those samples coming in, except as I incidentally saw them coming in.

Q. You think your recollection is you saw samples coming in in the morning?

2227 A. Yes sir, that's my recollection; not early in the morning, probably around eleven o'clock, or so.

Q. Now when you made the determinations for chlorine, for instance, you put down in your own handwriting in the book kept by you, that determination?

A. Yes sir.

Q. So many parts per million, I presume?

A. We put down all the figures connected with the determination, not merely the final result in parts per million, but the two readings which were taken to determine that. That is we read the burette before making the determination and afterwards and then substracting those two readings, and the diffrence represents so many parts per million.

Q. Now how many entries in the book was it necessary to make in order to determine the parts per million of chlorine for instance?

A. It required two readings and the result.

Q. Now in the first place you found upon the samples a tag?

A. Yes sir.

Q. With a number?

A. Yes sir.

Q. And the statement of the place from which it was taken?

A. Yes sir.

2228 Q. The temperature of the water and the air, didn't you?

A. Yes sir.

Q. Did you put them all down in a book?

A. We put down the place and number,—that is we always put down the number.

Q. Did you always put down the place?

A. I think very nearly always, but I wouldn't be positive as to that.

Q. Now did you put down the temperature of the water?

A. No sir.

Q. Or of the air?

A. No sir.

Q. After you had recorded so much as you did, off the tag, what was next put on the books?

A. Well, the books were ruled up for the different determinations.

Q. I am confining your attention at this moment to the chlorines?

A. Well, there was a column in which we put down the initial and final readings of the burette, and then the third column.

Q. That would be two entries?

A. That would be two entries, and then there would be the third column for parts per million.

Q. And that third column would be arrived at by subtracting the second from the first wouldn't it?

2229 A. Well, possibly we would need an extra column in there because one cubic centimeter represented ten parts per million so the result would have to be, if you substracted your results, as to cubic centimeters, you would have to multiply your result by ten for parts per million.

Q. Now do you remember whether you put down that column from which the multiplication arose?

A. The multiplication of it is to be done afterwards.

Q. You substracted and carried out the multiplication and then put down the final result?

A. It was merely changing the position of the decimal point.

Q. After the subtraction?

A. Yes sir.

Q. Now when you got that down in the book it was afterwards transcribed onto the sheets was it?

A. Yes sir.

Q. Onto these sheets and such sheets as you have now before you?

A. Yes sir.

Q. Well, the determinations in the book were each for a different sample?

A. Yes sir.

Q. And on different days?

A. Well, the determinations of record in the note books
2230 was kept in regular order; that is, numbered.

Q. According to number?

A. Yes, according to number.

Q. That determination was for every day, for daily samples from some particular place, each of a number of particular places?

A. Yes sir.

Q. Then you added up those determinations and divided them by seven?

A. Yes, after sorting them out, collecting and transcribing the results onto these sheets, we put all of the results on one sheet and from another point onto another sheet, that is, separated the different points.

Q. You never transcribed from your book literally, line for line and figure for figure, the result of each day's determination of each sample, onto the sheet did you?

A. You mean those extra columns that you were speaking about?

Q. Yes?

A. No sir.

Q. Did you transcribe from your book each day all the results of the final results of the determinations for chlorine, for example, from your book, each day onto the same sheet?

2231 A. No sir, that wasn't done until afterwards. This transcribing, if that's what you mean, wasn't done every day.

Q. You don't understand me. Did you ever transcribe from that book upon a sheet the result daily of the determination of chlorine of each sample analyzed that day?

A. All results were transcribed onto these sheets for every analysis that was made; the results were put onto these sheets in the order in which they were made from each place. That is, say the first month and second month and so on in regular order.

Q. You don't understand me, I am afraid. Suppose you analyzed a sample on the 15th of February, 1901, of chlorine?

A. Yes sir.

Q. And suppose, in addition to that one sample you analyzed thirteen others on that day?

A. From different places?

Q. From different places.

A. Yes sir.

Q. Now each one of those determinations was put down in a book?

A. Yes sir.

Q. Making thirteen separate entries upon thirteen separate horizontal lines, for those thirteen samples?

2232 A. Yes sir.

Q. Now then, did you ever transcribe those as they were for that day upon any sheet, each one of the thirteen?

A. Taking them in the same order?

Q. Yes.

A. No sir.

Q. Did you ever transcribe those as for one particular place for instance, the Intake Tower on the one particular sheet?

A. Taking all these from the Intake Tower on the days as they succeeded each other, on the one particular sheet?

Q. Yes.

A. Yes sir.

Q. Now for example, suppose if you took samples from January 3rd to January 10th, 1900, at the Intake Tower, and you analyzed them for chlorines, and you set down in your book the results of the analyses of each sample during that week from the Intake Tower, did you then copy that directly upon a sheet, each one of the seven?

A. Yes, each one of the seven.

Q. What sheet is that upon?

A. That is, personally I didn't make those, but I checked everything. I didn't do the clerical work.

2233 Q. I am not confining you to that. Take one sheet, the top one for instance, and show me on that sheet where is recorded the daily results of the analysis taken as to the particular element mentioned there, at a particular point?

A. Do you want to see it?

Q. Yes.

A. Here is the sheet (showing table to counsel).

MR. JOHNS: Intake, Chain of Rocks, 1901, November 1st to November 30th. That's the heading.

Q. In the first column headed "Total" the figures on the first line are 1175, what does that mean?

A. That is the residue on evaporation and the parts per million.

Q. Of one particular sample?

A. That particular sample taken at the Intake on November 1st.

Q. No. 6007?

A. Yes sir.

Q. And those are each set down there?

A. Yes sir.

Q. And that was done?

A. Some of them were, either done—

Q. By you or under your direction?

2234 A. They were all checked up, yes sir, that is by Mr. Miller and myself.

Q. Now have you in addition to these, weekly averages made up from these daily tables?

A. We have on this night work that was done in 1901, weekly averages are made right onto these sheets, and the work done in 1900 they were made on separate sheets.

Q. Now then for 1900, as far as you know, you put down upon these tables, the results of the daily analyses of each sample?

A. Yes sir.

Q. And in 1901 you put down, as far as you know, the weekly averages?

A. We put down the same thing, daily results for 1901.

Q. Of each sample, each day?

A. Each sample, each day.

Q. Well, in 1901, from that, did you make up weekly averages?

A. Yes sir.

Q. Now the weekly averages in 1901 were determined by whom?

A. Those were made by Mr. Miller and myself?

Q. All of them?

A. We had some help but we checked all that work.

2235 Q. Now the process of making that weekly average was to take one of those daily sheets and add up the seven days and divide by seven, wasn't it?

A. Add up the number of determinations made that week and divide them by seven, unless there had been a sample broken.

Q. Whatever the number of samples was?

A. Yes sir.

Q. And that result was set down upon the table which contains the weekly averages?

A. This separate table wasn't made out in 1901, but it was in 1900.

Q. I misunderstood you.

A. Those results were kept right on these same sheets in 1901, you can see them.

Q. But were the results kept and reduced to weekly averages in 1900?

A. Yes sir, and put on separate sheets.

Q. Then the correctness of these results as weekly averages depended upon the correctness with which the columns were added and the divisions made, and the transcriptions from that addition and division correctly transcribed onto the tables?

A. Yes sir.

2236 Q. If a mistake was made, in the addition or in the division or in the transcription, then that table wouldn't be correct?

A. No sir.

Q. Now when you say "checked up" the same thing, what was it you checked up after it had got onto the tables?

A. This work was all done by one man and then done by another man independently and if the results didn't check why we found out where the mistake was.

Q. What two men?

A. They were independently done by two different men.

Q Did you and Mr. Miller do that as a rule?

A Yes sir.

Q. How many other people worked at it?

A. In 1900, we had while we were at that work, four assistants, I think.

Q. Now whose work did you check?

A. Well, there is a difference between the work in 1900 and 1901. In 1901 the work was kept practically up to date, on these record sheets, and in 1900, these transcriptions were not made until afterwards, and then in 1900, we had a great accumulation of results there which had to be worked up and

2237 transcribed onto these sheets. For instance, in the ammonia readings, there would be say ten readings, which it was necessary to add, and that work was done by those assistants and checked by us. The checking not necessarily by us, but checked by two men independently.

Q. That is to say, two different men added up certain readings and divided up the proper number, and if their results were the same, then it was concluded to be the correct result and recorded?

A. Yes sir.

Q. Now in 1900, was this work of making the tables done daily at the time the analyses were made?

A. No sir.

Q. Were they done after the work was completed?

A. Largely, yes sir.

Q. After the active work of analyses was completed, these tables of results were made up?

A. They were made up from the note books.

Q. Where in the meantime were those note books?

A. They were kept in the safe locked up, in the City Chemist's office.

Q. In whose custody?

A. Dr. Teichmann's.

Q. Who had the combination of the safe?

A. Yes sir.

2238 Q. Did anybody else?

A. I think Mr. Buckland had it.

Q. Now in 1900, if I understand you, they were kept up pretty well, to date, all these tabulations?

A. Yes sir.

.Q Now when you say that one of these tables was checked up by you and Mr. Miller, do you mean to say more than that you checked the results of such calculation as you made, with some other person that was making the same calculation at the same time?

A. In the actual additions that I spoke of, in the ammonia readings for instance, where you have a number of results, when you have read a number of tubes and you add those, and the sum then is what you take, those additions were all checked up by two men,

Q. They made all the additions?

A. Well that is, four men and Mr. Miller and myself, we made all those additions.

Q. Now, if the ammonias that you were instancing, for the ammonias, two men added up independently these readings?

A. Yes sir.

Q. And then finding that they corresponded, they were taken as correct and transcribed?

2239 A. They were transcribed onto those sheets by some clerk.

Q. Now in checking that work, you checked so far as you added, some of these readings, that somebody else had checked up?

A. They were checked by being added by two different people.

Q. That's what you mean by checking?

A. That is, checking that addition; then they were transcribed, and Mr. Miller would either take the sheet or I would take the sheet, either way, and put it on the other side, then the transcription was checked from the book onto the sheets for the daily results.

Q. Now these additions or readings, and divisions to determine the weekly averages, were they set down on separate sheets? Different average sheets?

A. Those additions were made right in the note books.

Q. In which they were made?

A. Yes sir.

Q. Then when the weekly sheet, the sheet of weekly averages was made up, you would either read off, or Mr. Miller would, the result as found in the book and either one of you would transcribe it?

A. The daily sheets you mean, don't you—not the weekly?

Q. I understand you that these weekly averages were de-

2240 termined and put down from the original entry books?

A. Those weekly averages were made from those transcribed sheets.

Q. They weren't made from the original entry books at all?

A. No sir: Here is a sheet showing that if you wish to see it.

Q. Wait a moment. Then the weekly averages weren't set down in the books of original entry?

A. No sir.

Q. They were made up on sheets from these daily sheets?

A. They were made up on the daily sheets.

Q. Now after they were made up on the daily sheets they were transcribed again onto the sheets for weekly averages?

A. Yes sir.

Q. Who did that?

A. Mr. Miller and I, I think, did all of that.

Q. Now have you a sheet there, of these weekly averages as calculated and set down from the daily results upon the same sheet?

A. Yes sir.

Q. I have in my hand now the paper of water analyses, and on the first line is the reading 6768—Intake, Chain of Rocks, 1901, December 1st, and running in that style until December 31. When you had this sheet in your possession, to be 2241 transcribed into weekly averages, did you add up this column under the head of free ammonia?

A. Yes sir.

Q. And determine that it was 586?

A. Yes sir, that is either Mr. Miller or myself did that. We both did it. One did it and the other checked up.

Q. It had previously been added by someone else placed there?

A. No sir. I think we did that work personally.

Q. After that was done upon this daily sheet, those results were transferred to another sheet?

A. In 1900, but not in 1901.

Q. Now how many persons did this work of adding and dividing and putting down the results in the daily sheets in 1900?

A. Six of us. Not in entering these figures here, but in checking. In 1900 we had a great deal of that work to do, and we very often had two or three men checking at the same time. That is, one man would add that and another man check it and Mr. Miller and I always checked them all ourselves.

Q. So if on this sheet which I have described, if some person other than you or Mr. Miller, added up the column for free ammonia and made it 586, and the average 84, then either you or Mr. Miller again added up?

A. Yes sir.

2242 Q. Before it was transcribed into the books?

A. Yes sir.

Q. And was that the universal rule?

A. Yes sir, we personally checked every one of those additions and the divisions.

Q. Well, if you did that personally as to everyone of those weekly averages, what was the necessity of having somebody else add it up beforehand?

A. I don't think there was any one added it up beforehand. It is simply added by Mr. Miller and me; we did all this, the final additions and divisions in getting the weekly averages.

Q. I understood you to say that there were four or five different people doing this work of checking, in addition to you and Mr. Miller?

GENERAL CROW: You misunderstood him.

THE WITNESS: I think you misunderstood me; I didn't mean this part of the work; they were checking on the other work.

Q. On what other work?

A. On getting these results from the note-books onto the sheets?

MR. JOHNS: On to the tables?

A. Yes. But on this work, Mr. Miller and I did it.

Q. On the work of transcribing or determining the averages you and Mr. Miller worked exclusively?

2243 A. Yes sir.

Q. But the other people did the work, the several other people did the work of transcribing from the book onto these sheets, setting forth the daily results?

A. Yes, doing the clerical work.

Q. Now as to these daily results done by other persons did you and Mr. Miller compare them with the book from which they were taken?

A. Yes sir.

Q. In each instance?

A. As I recollect it.

Q. Entirely?

A. Yes sir.

RE-DIRECT EXAMINATION BY ATTORNEY GENERAL CROW

Q. What you and Mr. Miller actually did with reference to these sheets was to determine that the sheets were correctly made from the original data made in the books?

A. Yes sir.

Q. And you did that?

A. Yes sir.

2244 ## ALEXANDER N. MILLER.

called as a witness on behalf of the Complainant being first duly sworn by the Commissioner, testified as follows:

DIRECT-EXAMINATION BY ATTORNEY GENERAL CROW.

Q. What is your name?

A. Alexander N. Miller.

Q. Give your residence and occupation, please?

A. I live at 5222 Delmar Avenue and am employed by S. B. Russel a local consulting engineer as chief draughtsman.

Q. What is your profession?

A. I am a graduate civil engineer, that is I am a graduate in civil engineering. I have not a degree of civil engineer but as a B. B. C. E., a Bachelor of Science in Civil engineering.

Q. Have you ever studied chemistry?

A. Yes sir.

Q. Where?

A. In connection with my course in civil engineering at the University of Cincinnati from which I graduated in 1897. I studied chemistry for a period of two years, including qualitative, quantative and organic chemistry

2245 Q. What experience have you had as a chemist?

A. Since graduation I have been employed by Mr. George W. Fuller at Louisville, in connection with an investigation to determine the most feasible method of water purification in that city, and also at Cincinnati for a period of one year and about a month—

Q. What work, if any did you do on the waters of the Ohio River in connection with your employment with Mr. Fuller?

A. I made a large number of analyses of the Ohio River water at Louisville, Kentucky in January 1897, as I remember, for a period of three months, under Robert S. Weston and Mr. Fuller.

Q. That is at Louisville?

A. Yes sir.

Q. Did you do any work in Cincinnati?

A. At Cincinnati, Mr. Fuller had started the investigation there on filtration work and I helped Mr. Ellms the principal assistant to Mr. Fuller preparing solutions for that investigation, and also did analytical work for a period of one month after the work had started.

Q. And what other experience have you had as a chemist, as a water analyist?

A. I have had no other experience as a water analyist with the exception of the regular analyses at school. I
2246 made a few analyses of water there.

Q. Didn't you have some experience here in water analyses?

A. Yes sir. Outside of this investigation I mean.

Q. By whom were you employed as a water analyist here?

A. I have been employed on this investigation by Dr. Teichmann, City Chemist.

Q. When did you first go to work for Dr. Teichmann?

A. Went to work for Dr. Teichmann on November 26, 1900.

Q. How long did you work at that time?

A. I worked until January 8th as I remember, 1901.

Q. Then did you work any other time on these waters?

A. No sir, not until I was called back here from Pittsburg in 1901, September 6th about.

Q. Then how long did you work?

A. I worked until January the following year, January 8th or 9th.

Q. Did you work any other period than these two mentioned?

A. Not on these rivers, not on the river water at this point.

Q. Well, in what capacity were you employed in January and February 1900, to January 1902?

A. As analytical chemist under Dr. Teichmann.

Q. Now, what work did you do, where did you do it and what was the work performed upon, what samples and where?

A. I performed the work on various samples from points
2247 of collection from Lake Michigan, down on the Illinois
River to the City of St. Louis, Intake, etc., and also during that period I made one trip up the river to determine the amount of oxygen dissolved—dissolved oxygen in various waters.

Q. Now what particular portion of the work in the City Chemist's office did you perform?

A. While I was at the City Chemist's office in 1900 I made at various times all the determinations that were made with the exception of the ammonias as during that period the work was divided up amongst the different assistants and in that way I managed to perform the different determinations, or I managed to perform for certain periods, all the analyses.

Q. Mr. Goetz worked there at the same time, same period of time, did he not, that you did?

A. Yes, sir.

Q. Now, were any entries made of the data obtained as the result of the analyses of these waters?

A. Entries were made daily in record books which were properly ruled up for that purpose by the different analysts.

Q. Now, did you have anything to do with the transcribing of the notes in those entry books, onto any large sheets?

A. As I said before, we came here in February, Mr. Goetz and myself came here in February, 1900, and worked on these
various tests until October, 1900, when the investigation
2248 ceased and during the period October, 1900, to December,
1900, we were engaged in transcribing records and during that period we had a corps of four or five other assistants and they assisted in making additions and divisions to obtain the

proper daily record which was transcribed onto the official sheets, and their work was either checked by myself or Mr. Goetz—by Mr. Goetz or myself.

Q. The work of these assistants was all performed under your and Mr. Goetz immediate supervision?

A. Yes, sir.

Q. Now, have you got there in front of you the analytical sheets upon which this data was transcribed from the books?

A. Yes, sir.

Q. Now, after that was transcribed onto these sheets, was it checked by anyone?

A. Yes, sir; it was checked; that is while we were there it was checked either by Mr. Goetz or myself.

Q. Now, in what manner did you check that, just describe it?

A. Why, these books, these daily record books contained the records of analyses as put down by the chemists. Now, most of those chemists took no part in making the transcriptions, so it was necessary for us to check up their work and see that it was transcribed onto these official sheets correctly.
2249 Now, we were assisted by four men who made the necessary additions to obtain these results and we always saw that their work was thoroughly gone over and checked.

Q. That is the additions that they made?

A. Yes, sir. These men were not experienced chemists, although they could do clerical work accurately, very accurately, although it is necessary to check them, as I said before.

Q. Well, then, after the work was put onto those sheets was it again checked?

A. Yes, sir; it was called off, that is the daily official result as recorded in the daily record book was transcribed onto these sheets and checked by either Mr. Goetz or myself, so that these figures on the sheets represent the figure as recorded in the book, in the daily record book.

Q. Well, then, all of the sheets during the two periods of time which you mention that you were employed there were checked and the correctness tested by yourself and Mr. Getz?

A. That is while I was there?

Q. That is what I say, during the period of time that you were there?

A. Yes, sir.

Q. Now, can you testify as to whether or not those sheets
are correctly made from the data that was obtained from
2250 the analyses of these water samples?

A. Those sheets were correctly made as far as we know, up until the time we left the City Chemist's office.

Q. Now, can you describe the method that you used there in the determination of solids?

A. In making the solids determination there were two different determinations to be made, that is, we found the soluble solids, the solids in solution and the suspended solids. In order to find the dissolved solids we first filtered the sample perfectly clear through filters that had been previously washed and one hundred cubic centimeters of that filtrate were put into a platinum dish which had been thoroughly dried and weighed before the water was put into it and then it was put onto a water bath and the contents were evaporated to dryness and it was afterwards put into a bath which holds the temperature constantly at 100 degrees, or within a few degrees of 100.

Q. Of what, heat?

A. One hundred degrees centigrade, boiling point, so that all excess moisture was driven off. It was kept so for about a period of one hour and then it was put into a dessicator and cooled out of contact with the air. Then it was again weighed. I might say that in that dish there is a calcium chloride to extract the moisture from any air that is in there. Did I say that
it had been weighed? Well, it was weighed then, and
2251 then the difference in these weighings represents the
amount of dissolved solids. To get the total solids we go through the same operation only the water is not filtered. That is, you take 100 cubic centimeters of the water, evaporate it to dryness in a platinum dish, weigh it afterwards and subtract, and the result represents the total solids. To get the suspended solids we deduct the dissolved solids from the total solids.

Q. Now, what process did you follow there for the determination of the nitrites?

A. Well, it was only necessary that those determinations should be made. They were made by different chemists and the order was of no consequence, in which they were made, except you might say this, that the nitrites, free ammonias and nitrates, were the most important determination, and they should be made immediately on receiving the sample.

Q. Then, in the matter of obtaining the solids there in suspension, or the total solids, is a matter that would not be particularly affected by the time in which it was made?

A. No, sir.

Q. In other words, it could be made last as well as first?

A. Well, it would not be well to allow that period to be too great. It is necessary to make the tests as soon as possible after receiving the sample.

2252 CROSS-EXAMINATION, by Mr. Johns.

Q. The process of determining these various things in the laboratory is substantially the same or exactly the same, as described here by Dr. Keiser?

A. The regular standard methods of water analysis as followed by all water chemists.

Q. Now, you made some trips up the river, you say, to determine the dissolved oxygen?

A. Yes, sir.

Q. Is that the same thing as oxygen consumed, in some tables?

A. No, sir.

Q. What is it?

A. Oxygen consumed means the amount of oxygen consumed in oxidizing carbonaceous organic matter in the water. Oxygen dissolved in the water means the actual amount of oxygen dissolved by the water. I might add that fish breathe the oxygen out of the water just as we do out of the air and that dissolved oxygen is necessary in the water for the life of fish. It has nothing to do with oxygen consumed.

Q. Well, now, how did you determine the oxygen dissolved?

A. Oxygen dissolved in water is determined by means of
2253 Wenkler's method.

Q. Well, I am no wiser now than before, what is the method?

A. Those methods are rather hard to repeat off-hand and before going through an analysis of that kind it would be necessary to refer to notes in order that you would get the various quantities correctly, but I can give you the general method.

Q. Well, give me the general method?

A. Wenkler's method of determining dissolved oxygen consists in adding a quantity of sodium hydrate to the water, and also a quantity of manganous sulphate. As I say, these are not official figures, the strength of these solutions I could not give.

When these two re-agents are added to a given quantity of water, to a measured quantity of water, which is determined beforehand, there is a certain reaction which takes place between the sodium hydrate and manganous sulphate and manganous hydrate is formed which is easily oxidized and takes up oxygen from the water, takes up all that there is present and forms a manganic hydrate. Now, after that manganic hydrate is thoroughly precipitated, which can be judged by looking at it or observing it, a certain quantity of hydrochloric acid, concentrated hydrochloric acid is added, and this manganic hydrate is broken down to the manganous
2254 chloride again and the oxygen that had been taken up is liberated. After that oxygen is liberated, or before, I might say, there had been a re-agent called potassium iodide added. That acid and the oxygen which is liberated by the breaking down of the manganic hydrate acts upon the potassium iodide and liberates the iodine and from the amount of iodine liberated and by mathematical calculation you can tell how much oxygen there was dissolved originally in that sample.

Q. How do you estimate the iodine liberated?

A. The iodine liberated is estimated by titration, with sodium thiosulphate. Now, as I said before, going through that determination, it would be necessary for me to refer to notes.

Q. As to the quantity?

A. Yes, sir.

Q. Well, I don't care about that?

A. That is the general method, that is the Wenkler method.

Q. Now, I still do not understand how you arrive at the oxygen consumed, whether by building up other re-agents and making the comparison—

A. Well, we have been talking about dissolved oxygen, you remember?

Q. That is what I meant, dissolved oxygen, I beg your
2255 pardon. I do not understand, I do not get into my head,
how you determine the amount of oxygen consumed?

A. Well, as I said before, that oxygen liberates an equivalent quantity of iodine in that process, and although we have no direct method of getting at the oxygen we have a direct method of getting at the iodine.

Q. That is the way you determine the oxygen dissolved?

A. Yes, sir.

Q. By measuring this iodine?

A. Yes, sir.

Q. If I understood you, Mr. Miller, the results of the determination of the various analyses were set down in books by each analyst?

A. Yes, sir.

Q. And then those were copied off on the daily sheets, were copied onto daily sheets?

A. Yes, sir.

Q. And from those daily sheets another table of weekly averages was made?

A. Well, that weekly average was made on the daily sheet.

Q. But then it was copied off onto another tabel afterwards?

A. Yes, sir; that is during the period of 1900. That was
done during the period of 1901, while we were there, that
2256 was not done for the reason that we were rushed with
work and we were employed by the day.

Q. And afterwards you made up for 1901 those weekly averages?

A. Yes, sir.

Q. And in the manner in which you have described?

A. Yes, sir.

Q. Now, while you and Mr. Goetz worked there, do I understand you that you two gentlemen made up all those weekly averages?

A. Yes, sir.

Q. When you came to a table of daily results which some other person had added up and divided, did you, if you were handling the table, add up again the same results, to see if it was correct?

A. Yes, sir.

Q. And in each instance, as to each result?

A. Yes, sir. That is while we were there we saw that there was a thorough check on all the transcriptions and weekly averages that had been made up until the time that we left.

Q. Well, I am asking you, when you took the tables, daily results, upon which the weekly averages had been inserted
2257 by some one else, of daily results?

A. Yes, sir.

Q. In the same manner substantially as in that sheet before you?

A. Yes, sir.

Q. And then after that was done, they were transcribed onto another table?

A. Yes, sir; during the period of 1900 and also during the period of 1901.

Q. Now, you two gentlemen, if I understand you, did all of that addition to determine weekly averages?

A. To determine weekly averages, yes, sir. As I say, now I have a sheet before me which we did not do, which was made after we left there; but while we were there up until the time we left, we saw that those weekly averages were thoroughly checked.

Q. And then you say you saw that they were correctly transcribed?

A. Yes, sir. A. N. MILLER.

2258 JOSEPH F. SONDAG called as a witness on behalf of the complainant, being first duly sworn by the Commissioner, testified as follows:

DIRECT EXAMINATION, by Attorney-General Crow.

Q. What is your name?

A. Joseph F. Sondag.

Q. Where do you reside and what is your occupation?

A. I reside at 6806 Virginia avenue, this city.

Q. What is your business?

A. Well, I am a druggist by trade, but since October 1, 1901, I have been employed in the City Chemist's office as a clerk.

Q. Well, you are an assistant at the distillation table also?

A. Yes, sir.

Q. You took part in the analyses of the waters brought in from the Mississippi and Illinois Rivers?

A. No, sir; not the Illinois.

Q. Nothing but the Mississippi River water?

A. Only the Mississippi.

Q. What period of time now did you take part in these examinations?

2259 A. Since October 1, 1901.

Q. 1901?

A. Yes, sir.

Q. Last April?

A. Yes, sir.

Q. And then you have been there ever since?

A. Before this time I never had anything to do with this investigation.

Q. Now, what did you have to do with these analyses since April, 1901?

A. I made the distillations for the ammonias.

Q. Now, did you work under the direction of Dr. Teichmann?

A. Yes, sir.

Q. Did you make any entries in the books regarding the data for ammonia?

A. Yes, sir.

Q. Were the entries made by you in the original books?

A. Yes, sir.

Q. Did you do any transcribing of notes containing results of the analyses of water from the books in which the original entries were made on to the analytical sheets?

A. Yes, sir; I have done all that work since October 1, 1901.

Q. Well, are these sheets here that you have in front of

2260 you, those that you transcribed?

A. Yes, sir.

Q. Now, what period of time do they cover, from April, 1902, up to January, 1903?

A. I entered the records from October 1, 1901, up to—

Q. October 1, 1901?

A. Yes, sir; you see I entered all those up, to the last record—and the last record I made was July 31, 1902.

Q. Well, are those sheets there?

A. This is part of them, this is some of them.

Q. Where are the rest of them?

A. Some of them are down stairs, I guess.

Q. Now, did you transcribe anything on to any of these sheets from the original entry books, other than those things which you yourself put into the original entry books?

A. Yes, sir.

Q. Now, when you transcribed such data that you had not made in the original entry books, did you check up the original entry books to see that they were correct?

A. Yes, you know they would generally enter the readings, they would enter the number of the sample, where they were from, and then the readings, before thy would make the determination and the readings of the burette after the determination and they would put down the result, while I
2261 would take all these figures off.

Q. Now, in the original entry books there is nothing to be added but the reading for ammonia, is there?

A. That is all. Well, there is a determination made, you know, of parts per million.

Q. Well, is that entered in the original entry books, too?

A. Yes, sir.

Q. That would have to be added up?

A. Yes, sir.

Q. Did you do that?

A. Yes, sir.

Q. When you made these analytical sheets did you compare them with the books?

A. I copied them off the books onto the sheets, you know.

Q. And then did you add up the entries on the analytical sheets to see that they corresponded with the totals that were contained in the books?

A. Yes, sir—well, under the ammonia, all the adding I did in the ammonias was the final figures, of final determinations. The reading of the burette of parts per million is the only figure that is entered up on the sheets.

Q. Well, did you compare the work after you had got it done on the sheets with the original entries in the book?

2262 A. Yes, sir.

Q. Well, did you find them to be correct or incorrect?

A. Correct.

Q. Now, have you got the sheets there for the whole period of 1902, October 1, 1901, on up to the time you quit work?

A. They are not all right here, no.

Q. Where are they?

A. Part of them are down stairs, I guess. (Dr. Teichmann hands witness certain tables.)

Q. Did you get those sheets?

A. Yes, sir; I got them here.

Q. Well, then, you have all the sheets there, have you?

A. Yes, sir.

Q. And you are able to testify that those sheets were correctly made from the original entries as to the result of the analyses?

A. Yes, sir.

CROSS-EXAMINATION, by Mr. Johns.

Q. Do I understand you to say that all the sheets which are presented here, of daily results were made by you?

A. Since October 1st.

Q. October 1st, 1901?

A. Yes, sir.

2263 Q. Everyone of them?

A. Yes, sir.

Q. And transcribed by you from the books?

A. Yes, sir; onto these sheets.

Q. In making those sheets you didn't add up in the book the determinations for parts per million, but took them as correct in the original book?

A. I went over all the figures, I also checked them up myself, figured all the readings. I would take the reading of the burette before determination, say, for instance, on chlorides, and after determination, and the deduction is the result. I checked all that over.

Q. You checked all that over?

A. Yes, sir.

Q. For each determination?

A. Yes, sir.

Q. For each day?

A. Yes, sir.

Q. Of each sample?

A. Yes, sir.

Q. Then checked that parts per million?

A. Yes, sir.

Q. And found that that was correct?

A. Yes, sir.

2264 Q. Then you copied those parts per million under the proper columns in these sheets now before you?

A. Yes, sir.

Q. And that you think was correctly done?

A. Yes, sir.

Q. Did you make any sheets of weekly averages afterwards?

A. No, sir; I only figured the weekly average onto the sheets, the same as this.

Q. Now, are these figures of weekly averages there your figures?

A. Yes, sir; except two months, October and November of 1901.

Q. All the others are yours?

A. All the others since then are mine.

Q. Without assistance, did you do it individually?

A. Yes sir. Miller and Goetz did the work for these two months. They would compare them with books, one would take the books of the different readings and compare them with my figures. After they would get that all checked off then they would make weekly averages.

Q. But only for those two months?

A. Only for those two months, because they quit there 2265 about December 8, 1901, and since then after that, why we only took samples from the Chain of Rocks. Since then everything that was entered on the sheets was done by me.

JOS. F. SONDAG.

2266 **THOMAS A. BUCKLAND** resumed the stand for further direct examination, by Attorney-General Crow, and testified as follows:

Q. Mr. Buckland, what part of the analytical work of this investigation did you do?

A. Well, you are referring to the time of 1901?

Q. You testified about what you did before?

A. Yes, sir.

Q. I am referring to the time in 1901, after the close of the first original investigation.

A. That was the second original investigation.

Q. Well, the second; after the close of that period of time?

A. Well, I made all the analytical determinations.

Q. Well, what waters did you work on, what rivers?

A. Well, the Mississippi principally, I think. We had a few samples from Grafton and other places.

Q. Well, out of the Illinois or the Mississippi?

A. Yes, I think there were some from both the Illinois and Mississippi, some few, I don't remember the number, that is on the record.

2267 Q. Well, what determinations did you make from these samples and during what period of time were they, just state the dates?

A. Well, from the time that the large investigation—

Q. Well, when was that?

A. Well, I am not able to state the exact date.

Q. Well, just as near as you can, some time after 1901?

A. After the samples, after the large number of samples ceased coming—

Q. The early fall or in the winter?

A. In the winter, yes, sir.

Q. At what time of the year?

A. I think it was about December.

Q. What year?

A. 1901.

Q. Now, from that time on until January, 1903, did you make determinations?

A. Yes, sir.

Q. For what?

A. For ammonia, nitrites, nitrates, chlorine, alkalinity and oxygen consumed. I did not, however, make all the determinations on all the samples.

Q. Who recorded the results of that?

A. Well, with the exception of the ammonia results I recorded the results myself in the small books which were 2268 provided for the purpose.

Q. Who transcribed that on to these analytical sheets?

A. Mr. Sondag, I think.

Q. Now, do you recognize that as any of the work that you did as the result of that analysis (handing witness large sheet)?

A. Well, these were not copied on here by me, my results were entered into the small book.

Q. Well, then, you don't know whether that is correct or not?

A. No, sir. I have no doubt it is, but as I did not copy it on the sheets I cannot state that it is.

Q. Well, do you know from your recollection, as to whether or not you find high free ammonias in December, 1901, in the Illinois River at Grafton?

A. Yes, sir; I found the ammonias quite high.

Q. Do you know what was the maximum amount you found and the date of it?

A. I cannot remember the date. It was somewhere in the neighborhood of one part per million.

Q. That would be 1.?

A. Yes, sir, 1.

MR. JOHNS: One whole number?

2269 A. One whole number.

Q. Well, have you any recollection as to how the ammonias run, whether high or low during the subsequent months, for the samples taken at the Intake?

A. They were rather high, according to my recollection.

CROSS-EXAMINATION, by Mr. Johns.

Q. What caused the ammonia to run high in the Illinois River at that time?

A. Well, I am not prepared to state what made it run high.

I can state just what was found in it. I presume it was from pollution in the Illinois River from farther up.

Q. Do you know the state of the ammonias in the Mississippi at that time?

A. According to my recollection they were lower, the free ammonia was lower.

Q. I am asking you, do you remember the state of the Mississippi as to the ammonia on that same day?

A. No, sir.

Q. Do you remember the state of the Missouri as to ammonia on the same date?

A. No, sir.

2270 Q. Do you know whether the Mississippi was at that time as to ammonia, higher or lower than a fair average?

A. No, sir; I am not able to state.

Q. Do you know whether the Missouri at that time was higher or lower than a fair average?

A. No, sir.

Q. But you do recollect, you think, that the ammonia at the intake tower was high, ran high?

A. About that time, yes, sir.

Q. Yes, about that time?

A. Yes, sir.

Q. But, from what cause you don't pretend to state?

A. No, sir.

THOS. A. BUCKLAND.

Adjourned until 10 a. m., Monday, March 23, 1903.

2271 Met pursuant to adjournment at the same place at ten a. m., March 23, 1903. And thereupon an adjournment was taken by consent until ten a. m., March 24, 1903.

Met pursuant to adjournment at the same place at ten a. m., March 24. And thereupon an adjournment was taken by consent until ten a. m., March 25, 1903.

Met pursuant to adjournment at the same place at ten a. m., March 25, 1903. And thereupon an adjournment was taken by consent until ten a. m., March 26, 1903.

Met pursuant to adjournment at the same place at ten a. m., March 26, 1903. And thereupon an adjournment was taken by consent until March 27, 1903.

Met pursuant to adjournment at the same place at ten a. m., March 27, 1903. And thereupon an adjournment was taken by consent until March 28, 1903.

Met pursuant to adjournment at the same place at ten a. m., March 28, 1903. And thereupon an adjournment was taken by consent until Monday, March 30, 1903, at ten a. m.

2272 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Monday, March 30, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel as before, representing the respective parties.

DR. WILLIAM C. TEICHMANN, resumed the stand for cross-examination, by Mr. Johns, and testified as follows:

Q. Dr. Teichmann, what is your idea or reason for calculating the volume of the Illinois River and its flow per minute of cubic feet, or per second of cubic feet, to place it at the extremest low water that you could find data for?

A. The low water stages are the most important in my opinion, in calculating the effect of the sewage on the Illinois River, because of the lower volume of water producing a lower ratio of dilution.

Q. Why not, if you wanted to strike a fair average of the ratio of dilution, select a mean stage of water?

A. Because a mean stage would be a theoretical condition, whereas, the low stage would be calculating on the basis of an actual condition as it occurred. In other words, the low stage found at a certain time would be liable to return again
2273 and then the condtions would be such as to produce a ratio of dilution much lower than the average would be, and we should then, as I have said, have an actual condition to base our calculations on for future determinations.

Q. Then you take the position that you cannot ascertain the mean stage of the Illinois River?

A. Yes, sir, the mean stage can be ascertained.

Q. Well, if it can be and has been, why not take it instead of the lowest stage?

A. Well, because, as I said, the lower the stage of the Illinois River is, the smaller will be the dilution of the sewage in the river.

Q. The idea was to calculate the smallest amount possible of dilution for the purposes of calculation of the dilution of the river then?

A. Yes.

Q. Well, a low stage of water might continue for a day or a week or ten minutes, might it not?

A. Yes.

Q. The very lowest stage?

A. Yes.

Q. And the very lowest stage is extremely rare and a very unusual thing, is it not?

2274 A. Well, that depends upon the weather conditions very much.

Q. Precisely. But the very lowest stage of the river is the thing which occurs less frequently than an average or a mean stage of the river, is it not?

A. Yes, sir.

Q. Now, where did you get your figures for the low stage of the Illinois?

A. I got those from a report published by Lyman E. Cooley, formerly chief engineer of the Chicago Drainage Canal.

Q. Made when?

A. In the year 1890.

Q. In 1890?

A. Yes.

Q. Have you any data as to the stage of the Illinois River at any time from 1890, to 1899?

A. Yes, sir.

Q. Have you it with you?

A. Yes, sir.

Q. From what reports did you get it?

A. I got those records from reports published by the Illinois State Board of Health up to 1899.

Q. In which the stage of the Illinois River was given at various times?

2275 A. Yes, sir, by Civil Engineer Harman.

Q. Well, why did you not take some time nearer to the opening of this canal than 1890, as the basis for your data?

A. Well, I thought that the lowest stage on record would be exactly the stage to take because it might possibly recur again—this lowest stage, and the lower the stage of the river of course the smaller will be the amount of water for dilution of the sewage in the river.

Q. And the worse then the amounts of pollution shown on the charts?

A. Yes, sir.

Q. Now, if you will take a piece of paper and a pencil, I want you to make a calculation for me.

A. Yes, sir.

Q. In your testimony of March 17th, you have the lowest stage at Wilmington, on the Kankakee, 25,200 feet per minute. On the Des Plaines 256 feet per minute—

A. 256 feet per minute?

Q. Yes?

MR. WOERNER: Do you mean per minute?

MR. JOHNS: That is what the record says.

Q. And at another time you have for the Des Plaines, 339 cubic feet per minute.

GENERAL CROW: That must be per second, isn't it, doctor?

2276 THE WITNESS: Yes, I will have to look up my report to see what I testified to, because I took those data from the report. It is more likely to be per second, though.

Q. MR. JOHNS: In the Fox River, 31,339 feet per minute; the Mason River 15,000 cubic feet and the Canal at La-Salle 37,900 cubic feet. How many cubic feet per minute is that in all those rivers?

A. 110,034 cubic feet.

Q. How many cubic feet per second would that be?

A. 18,339.

Q. Now, all those rivers named are above Utica, are they not?

A. Well, I presume so; I don't know, but I think you are right.

Q. Then where do you get your basis of 600 cubic feet of water, upon which you calculate the basis of dilution and pollution?

A. Well, I got that from the figures as they were presented by Mr. Cooley, in his report, and I thought I had quoted them correctly, that is, figuring on the volume of water coming at the lowest stage on record there, from those rivers, and I calculated that out and my figures—the figures of Mr. Cooley agree with the figures produced by Civil Engineer Harman for the Illinois State Board of Health in his report; he finds that same volume,—600 cubic feet.

2277 Q. Answer the question and we will get along more rapidly. Assuming that the data as given you there are the figures from your testimony of March 17, the volume of flow was three times as much—yes, was thirty times as much as you gave—was it not?

A. Well, Mr. Johns, the question is whether my testimony on that day conveyed that idea. Of course I am not sure about that just now, but certainly the figures that I presented there would lead to the conclusion that the flow was considerably less than 18,339.

Q. Well now, how do you happen to assume the sewage of Chicago at 400 cubic feet per second?

A. 400 cubic feet per second?

Q. Yes.

A. Well, figuring on the amount of sewage coming from the Illinois and Michigan Canal, it is simply that the flow per minute is converted into seconds; they would have to take sixty times that; that would give you a certain figure per minute, and that would be the flow from that sewage.

Q. If you have any data or know any way in which you can figure that the sewage of Chicago is 400 cubic feet per second, state now what it is and how you arrive at that conclusion?

A. Well, that was at that time from the Illinois and Michigan Canal—

2278 Q. Based on what theory?

A. Well, based on the theory that there is 60 times—figuring on 36,000 per minute of flow.

Q. Of flow?

A. Yes.

Q. Assuming that the discharge from the Illinois and Michigan Canal was 36,000 per minute, and that 60 per cent of that flow was Lake Michigan water, 40 per cent of it then you say would be sewage?

A. Yes.

Q. From Chicago?

A. Yes sir.

Q. What is 40 per cent of 36,000?

A. That would be simply two-fifths—40 per cent would be 14,400.

Q. Assuming that that is Chicago sewage per minute, how many feet is that per second?

A. That would be 2400.

Q. 2400?

A. No, 240.

Q. Then were did you get your figures of 400?

A. Well, you must take the total volume of the sewage mixed with the water as it leaves the canal.

2279 Q. That is precisely what I am doing, and assuming that 60 per cent of the flow,—36,000 feet, is Lake Michigan water, dilution, and 40 per cent is sewage, as you say, then your statement of 400 feet per second for Chicago sewage, is incorrect, is it not?

A. No, I don't think so, because the sewage as it leaves the canal is supposed to be the sewage mixed with the lake water there. It is diluted sewage; you can't base the calculation on the sewage there, because it is mixed with the water and leaves the canal together; that is what is understood by the sewage leaving the Illinois and Michigan Canal. It is of course the sewage mixed with the water there.

Q. Well, you say at the ratio of 40 per cent sewage to 60 per cent Lake Michigan water,—so that your assumption of 400 feet was incorrect by 140 feet, was it not?

A. No sir, not the way I construe it, and the way Mr. Cooley and Mr. Harman construe it in their reports. They calculated on the total volume leaving the canal and entering the Desplaines River, or rather at LaSalle and call it all sewage.

Q. Answer this question: If the flow from the Illinois and Michigan Canal is 36,000 feet per minute, and if 40 per cent of that is Chicago sewage; then assuming that state of facts, without any argument with reference to it, your assumption of 400 cubic feet per minute of Chicago sewage is a mistake, is it not?

2280 A. No, I can't admit that, because the mixture there is still sewage; it is a sewage mixture—

Q. I beg your pardon. You are now on the stand as an expert, and I have a right to assume to you any question that I see fit to propound, in the way of legitimate cross-examination, and you are bound by the facts which I state. Being now bound by the facts which I state in that question, is not your assumption of 400 cubic feet wrong?

A. No sir.

MR. WOERNER: We object to the question on the ground that it is apparent that the witness cannot answer the question "Yes" or "No" without a further explanation, as to what he means by sewage.

MR. JEFFRIES: And which explanation he has already given.

Q. MR. JOHNS: Assuming that the volume per second of the Illinois River above Utica is over 18,000 feet, and that the sewage of Chicago is 400 feet per second, your rate of dilution of 1 to 5 is also incorrect, is it not?

A. Well, based upon your premise.

Q. Now then, assuming that the volume of the Illinois River above Utica before the opening of the Drainage Canal was in round numbers 18,000 feet, and that the sewage of Chicago was 400 cubic feet, per second; what is the ratio of dilution?

2281 A. The ratio of dilution would simply be their subtraction—400 there, and 18,000; that would be of course a very large ratio.

Q. Yes, well, what is it?

A. Forty-five.

Q. One to forty-five.

A. Yes.

Q. Well, that is a very considerable dilution, is it not?

A. Yes sir.

Q. Now do you know that in this calculation that you have made here of the stage of the Illinois River above Utica, you have left out a number of rivers—several?

A. Well, those rivers were left out because in the opinion of Mr. Cooley, their stages were such that they were practically dry during that season of drouth, so that Cooley omitted them from his calculations.

Q. Your entire argument upon the question of the dilution of sewage is based upon an opinion of Mr. Cooley, given in 1890?

A. Principally, yes, and also upon an opinion, in figuring out those stages and averages, in an opinion presented by Mr. Harman, the Civil Engineer for the Illinois State Board of health, published in 1901.

Q. Do you know anything as to the annual average stage of the Illinois River above Utica?

2282 A. Well, I couldn't tell you off-hand. I have looked over those publications, and am somewhat familiar with those stages, but I could not give you the exact figures off-hand.

Q. What do you define sewage to be?

A. Well, sewage ordinarily is defined as the liquid contents of the sewers, but this definition would have to be modified some because you cannot call it strictly liquid contents. It has solid matter in the contents of the sewers, so that you define it as the contents of the sewers.

Q. Sewage, as you use it, is the discharge of matter from cities through tubes into some place of exit?

A. Yes sir.

Q. Including all kinds of discharges?

A. Yes sir, various kinds of sewage.

Q. Do you know what the discharge of the sewers of Chicago was into places in which it was discharged before December, 1900?

A. Repeat that question.

Q. Do you know what was the discharge of sewage in Chicago in December, 1899?

A. That would have to be calculated with the water supply of Chicago. I calculated out that the water supply is equal to the amount of sewage every day. That is a general assumption that is based upon calculations of various engineers and it is usually resorted to. 2283

Q. And at how much per head, per day, that is per individual per day?

A. I would make it for the city of Chicago 42,000,000 cubic feet per day.

Q. Why do you make it that?

A. Well, based upon the water supply of the city of Chicago.

Q. Do you assume that there is pumped annually into the water surface of Chicago, 42,000,000 cubic feet per day of water?

A. What's that?

Q. (Question repeated)?

A. Yes, I base it on the water supply.

Q. You assume that there are 42,000,000 cubic feet of water pumped into the surface mains of the city of Chicago per day?

A. Yes sir.

Q. And then you assume that all that water becomes sewage?

A. No, I estimate the amount, the bulk of the amount of sewage which the city of Chicago produces.

Q. How do you know what that is?

A. Equal to the water supply.

Q. That is in determining the amount of Chicago sewage, you say that if there is pumped for the use of the city into its mains, 42,000,000 cubic feet of water per day, the sewage of the city of Chicago is 42,000,000 cubic feet? 228

A. Yes sir.

Q. Without any kind of deduction for any other use than the discharge into the sewers?

A. Well, that is an approximation, of course. The figure may not be absolutely correct, but it is an approximation that is accepted by all engineers, and practically all text-books on engineering. In figuring the volume of sewage produced every day, you base it on the water supply.

Q. And that is purely an assumption without any data to substantiate it at all, isn't it? It is a scientific argument?

A. Well, that's a scientific argument, though that is the basis upon which investigators carry on their investigations, engineers.

Q. By whom, for instance?

A. Well now, I cannot quote any particular one just now, but it is usually recorded in various text-books.

Q. By whomsoever it is created as a standard, it leaves out of the calculation the use of water for steam, for drinking purposes for animals and man, and for all purposes for which it is used, in which it does not afterwards escape bodily into the sewers?

2285 A. It is the daily consumption of the water; that is what it is based upon, of the city water supply.

Q. You don't understand my question. That estimation leaves out of consideration entirely the water used for steam and drinking purposes, or for any other purposes in which it does not escape into the sewers in the form of water?

A. No sir. It isn't to be understood that way. It is to be understood upon the consumption of water in the city, by the city water supply. That is, this data, as it is calculated by the engineers of the water supplies.

Q. If you will pay attention to my question. We will assume that the water supply of the city of Chicago is 42,000,000 cubic feet of water per day?

A. Yes sir.

Q. Then you assume that the sewage of the city of Chicago is 42,000,000 cubic feet per day?

A. Yes sir.

Q. That assumption excludes all the purposes for which water is used in the city of Chicago, except such purposes to which it is put as would return it in the form of water to the sewers, whether consumed by steam, for drinking purposes by man and animals, that is destroyed absolutely in manufacturing, as water, and disappears as water entirely. It excludes that amount of water, whatever it is, doesn't it?

2286 A. No, I don't think so. I think it is entirely the official consumption as recorded by the data of the engineers.

Q. But if the water is converted into steam it doesn't return into the sewers, does it?

A. No.

Q. And if the water is consumed and drunk by animal or man, it doesn't return to the sewer again as water, does it?

A. No sir, not necessarily.

Q. If it is destroyed in the purposes of some manufactory and its identity and character is so lost that doesn't again return to the sewer as water, does it?

A. No sir.

Q. Then the whole assumption excludes from use all water in the city of Chicago which doesn't return it to the sewers again as water?

A. I cannot agree to that.

Q. Now then, assuming that it is 42,000,000 cubic feet per day, how many cubic feet per minute is that?

A. Well, I would simply have to make a calculation of that —291,666 cubic feet per minute.

Q. Now where did you get your estimation of 400 cubic feet per minute for the sewage of Chicago?

2287 A. Well, that is the Illinois and Michigan Canal at that time. The total amount of the sewage of Chicago was not pumped into the canal at that time. Only a part of it.

Q. If the total amount was not pumped in, what would you say?

A. Well, that depends on the average that we take. I calculated on 36,000.

Q. Cubic feet per minute?

A. Yes sir.

Q. And that was the water pumped at the Bridgeport pumping works?

A. Yes sir.

Q. Now what is the effect of chlorine in water?

A. You mean chemically?

Q. Yes?

A. Well, the effect of chlorine is simply that it adds so much sodium chloride, the form in which chlorine is usually prevalent in the water.

Q. Well, it is a pollution, isn't it?

A. Well, a pollution only—you mean of organic origin?

Q. I don't care—of any kind of origin. I am asking you now the effect of chlorine in water?

2288 A. If you take absolutely pure water, aqua pura—it shouldn't have any chlorine, and adding chlorine to it, would be adding impurity to it.

Q. If you should take a potable water, how much chlorine would render it suspicious?

A. Well the chlorine as such might be comparatively high and yet that water would be potable.

Q. How high?

A. Its potability would depend upon the amount of organic matter present in the water in conjunction with the chlorine.

Q. Well, could you determine a standard beyond which water would be unpotable, with reference to chlorine alone?

A. Yes, the sodium chloride present in the water may be of such a large amount, of this chemical, that it would be injurious to the health.

Q. Well now, what amount would that be, parts per million?

A. Well, that would have to run very high. It would run perhaps in the thousands.

Q. Well, if you know, what is the per cent of chlorine alone in water, which makes it unpotable, tell me?

A. I couldn't tell you that limit from that standpoint, of its medical properties. It might be medical water. It might be good for certain diseases and contain very high chlorine. And then again, ordinarily such water would have such a salty character that it would be unpotable.

2289 Q. How much chlorine in water would make it unpotable to the average good, healthy Missourian?

A. I think, of course it is an approximation, it is very hard to tell, because a high amount of chlorine may be palatable to the stomach of one individual and it may not be palatable to the other. It is very hard to draw the limit there. There might be a thousand parts of chlorine in that water and yet people might be able to drink that water, and others again, would reject it; it wouldn't agree with them.

Q. I have asked you a plain, simple question. What amount of chlorine in water would make it unpotable to a resident of Missouri? If you know, answer it, and if you don't say so.

A. Well I claim that there may be as much as 500 parts chlorine in that water and yet it may be potable.

Q. If there is any standard, state it, for chlorine in potable water?

A. No standard would be recognized that would condemn water solely on its contents of chlorine.

Q. Now, when in water you find chlorine, it is a certain chemical constituent, isn't it?

A. Yes sir.

Q. Although it might be developed chemically from different sources, its effect upon the water is the same, it is chlorine, isn't it?

2290 A. Well, that depends whether it is present in conjunction with organic matter or not.

Q. I am talking simply and alone of chlorine, as a separate and distinct element of pollution in water, when it becomes what chemists recognize as chlorine, then it is a chemical constituent, which is a pollution, is it not, no matter where it comes from?

A. I wouldn't define it as a pollution.

Q. For instance, is there a difference chemically between the thing termed chlorine in water, when it comes from dissolved salt, and when it comes from a dissolved manure heap?

A. Certainly, there is a great difference.

Q. Now the thing itself is called chlorine?

A. I mean in its importance as an ingredient to the water.

Q. In itself, considered alone as a constituent in the water, isn't it the same when you find it, whether it comes from dissolving salt, or from a dissolving manure heap, chemically?

A. If you leave out of consideration everything else and simply look to the chlorine, why certainly, it is all the same. It it identified the same way and it is present.

Q. Now is it or is it not an element of pollution in water without reference to its source?

A. Soley as such it is not.

2291 Q. In no respect a matter of pollution?

A. Well, that depends upon what you define as pollution.

Q. Well, I will come to that in a moment. I am going to find out what is pollution pretty soon. As an element of pollution in water of itself, you think it cannot be called a polluting matter or a polluting substance?

A. Well, I would say that it may, if entering pure water, that it may add impurity to the water, but what is generally considered as pollution, I cannot class it with that.

Q. You cannot class it with that?

A. No sir.

Q. What is pollution in water, at any rate?

A. The general definition of pollution in water, is understood to be pollution principally by organic matter.

Q. And you do not call salts and minerals organic matter of course?

A. No sir.

Q. So that when you find chlorine in water, you cannot tell, considered by itself, and separate from all other things, whether it comes from organic matter or mineral matter, can you?

A. No sir, not by itself.

Q. What is the character of albuminoid in water? Is it one of the pollutions?

2292 A. Yes, I would call albuminoid ammonia, it is generally termed, having a number of organic compounds, that we obtain by certain analytical processes.

Q. Is it an element of pollution in water?

A. Yes.

Q. It is an evidence that in that water there must have been some organic substance?

A. Yes sir.

Q. When you find albuminoid ammonia in water, you conclude that there have been organic substances in the water which have become decomposed?

A. Yes sir.

Q. Now whether those organic substances are fecal discharges or the result of dissolution of plants, you cannot tell?

A. Yes, it may be either one.

Q. Or it might be both?

A. Yes. It might be a source of pollution from both, of animal and vegetable origin.

Q. At what time, if from vegetable origin, would albuminoid ammonia be the highest in the Mississippi River?

A. I don't understand the question.

Q. At what season of the year, if albuminoid ammonia was to be attributed to the decomposition of fecal matter, would it be the highest in the Mississippi River?

2293 A. Well, it would be during the summer months.

Q. June, July and August?

A. Yes, during the warm season decomposition proceeds more rapidly; fermentative processes are more active during the warm season than they are during the cold season.

Q. That would apply also to the Illinois River and Missouri River, would it?

A. It would apply very well to all rivers.

Q. And to all waters?

A. Yes sir.

Q. Wouldn't it be higher in the waters of the Illinois if they were attributable to organic substances, vegetable substances, rather,—in September, October and November?

A. Yes, as a result of the decomposition having taken place during the summer months, that is possible.

Q. Of vegetable matter?

A. Yes sir.

Q. Now when you find albuminoid ammonia for instance in water at Grafton, in the Illinois River, you cannot tell whether it is the result of the decomposition of fecal or organic matter or animal matter, can you?

A. You mean the Illinois River at Grafton?

Q. Yes.

A. We have to take into consideration there the general 2294 analytical results.

Q. I am not asking you to take anything into consideration except the albuminoid ammonia alone.

A. Repeat that question.

Q. When you find albuminoid ammonia in water in the Illinois River at Grafton, can you tell whether it comes from decomposition of animal organic matter or vegetable organic matter?

A. In a measure I will be able to distinguish approximately whether this albuminoid ammonia may be more of animal origin or of vegetable origin.

Q. You mean you do that from the consideration of the ammonia alone.

A. By comparing the analytical results for the albuminoid ammonia obtained from the sample analyzed of the filtered water and the sample analyzed from the unfiltered water, and also by comparing results for the organic matter as estimated by the oxygen consumed process. Also on filtered and unfiltered samples, and also taking into consideration the residue on evaporation and the total solids test. In finding out whether the residue on evaporation found in the suspension, that is in the suspended matter of the original sample, is high or low, and how it compared with the residue on evaporation found from the estimate of the total solids in the filtered sample. We take 2295 all these things in general together and that enables us in a measure to say approximately and form an opinion as to whether the albuminoid ammonia there may be of animal origin principally, or of vegetable origin. An exactly correct estimation in quantity may not be possible. It is an approximation, but in general we can draw some conclusions from these comparisons.

Q. Now take another thing about which we have been talking here, the nitrites for instance. You found nitrites in the Illinois River at Grafton. Can you tell whether they are from the decomposition of vegetables or animal organic matter taken by themselves?

A. That I cannot distinguish, not as such, no.

Q. Your theory is that the Illinois and Michigan Canal was in a way, a septic tank?

A. Yes sir.

Q. And that therefore the waters discharged from it into the Illinois River at Joliet were in a better condition chemically than the waters discharged into it by the drainage canal?

A. Yes sir.

Q. Did you ever make any chemical analyses of the waters of the Illinois River at Joliet before the opening of the Drainage Canal?

A. No sir.

2296 Q. Did you ever have anybody do that?

A. No sir.

Q. So as to what was the condition of the Illinois River at Joliet consequent upon the discharge of the water of the Chicago River through the Illinois and Michigan Canal prior to the opening of the Drainage Canal, you do not pretend to know?

A. Well as I have obtained some information from available data, published by reliable authority.

Q. By yourself or in an investigation made under your direction?

A. Not from my own personal analytical examination, no sir.

Q. Did you ever make any analyses of the waters of the Desplaines river at any point before the opening of the Drainage Canal?

A. No sir.

Q. So that you have no personal knowledge in any way of its condition chemically either above or below the place where the Drainage Canal flows into it?

A. Well, whatever information I was able to obtain from published data of responsible investigators, I have.

Q. From your own personal investigation?

A. Not from my own personal analyses of the waters.

2297 Q. Now if a septic tank is good at one place, it ought to be good at another place in the course of decomposition, ought it not, in the purification of water?

A. Yes sir.

Q. Whatever state of oxidation, up to purification, with a septic tank intervening, is to hasten the process of purification?

A. Repeat that question.

Q. Whatever state of purification has been reached, a septic tank would be beneficial and hasten the ultimate purification of the water, wouldn't it?

A. Well, after a certain water had already passed the stages that are represented in a septic tank, then after it has run through a septic tank again, that same water would hardly be benefited by the septic tank because the action of the nitrifying cycle produced by the aerobic bacteria follows the action of the anaerobic bacteria in the tank as far as that sewage is concerned, of course, and it would not be any benefit.

Q. If there were a series of septic tanks through which the same water flowed, each septic tank would of itself aid in the purification of the waters, wouldn't it?

2298 A. Well, if there were a balance of water leaving one tank which had not gotten the initial processes of purification, of course that water or sewage would be benefited by passing through the second tank, etc.

Q. In the upper septic tank, if, when the water left, there were found free ammonia and albuminoid ammonia, and nitrites, the passage of that same water through another septic tank would help the processes of purification, wouldn't it?

A. Well, it has been established that in these septic tanks the aerobic bacteria are present to a limited degree, and these aerobic bacteria by being present in subsequent tanks may to a small degree continue these processes of purification and produce a purified product, that is, as far as they are able to do so in that tank. The number of aerobic bacteria from investigations made, show that the number is very small but they are admittedly present in these tanks.

Q. Well, in the Illinois and Michigan Canal, there was some current of water? The water flowed through that canal, didn't it?

A. Yes.

Q. Do you know how rapidly?

A. I couldn't tell just now. I haven't got the data at hand.

Q. Have you any idea how rapidly?

A. The current is exceedingly slow and it depends very much
upon the amount of sewage pumped into the canal and
2299 how long it is permitted to be in the canal. It varies
greatly.

Q. If 36,000 cubic feet per minute pumped in, and 36,000 cubic feet per minute discharged, there must have been a current in the Illinois and Michigan Canal?

A. Yes sir, at that time.

Q. And if that was the average state and condition of the Illinois and Michigan Canal, it must have had somewhat of a current?

A. Yes sir.

Q. Now suppose that below where the Illinois and Michigan Canal discharged into the Illinois River, there was a stretch of river of say three miles, in which the current was very slow, scarcely perceptible, would that operate as a septic tank?

A. Three miles per hour?

Q. A stretch three miles long of the river?

A. Yes sir, it would.

Q. If there was another stretch of 23 miles, that would also operate as a septic tank?

A. Yes sir.

Q. And in any investigation of the Illinois River that you have made, a long and continued series of septic tanks would have been very beneficial, wouldn't they, to the purification?

2300 A. In a measure it would.

Q. Do you know anything about the grades and descents of the Illinois River?

A. Oh, I have a slight knowledge of the same, a study of reports written by responsible authorities.

Q. But only taken from authorities? You made no surveys yourself?

A. No sir.

Q. Do you know that upon the Illinois River there are a large number of bayous of lakes, adjoining the banks of the Illinois River, which are spring fed?

A. Yes sir.

Q. And which in low water discharges their water into the Illinois River?

A. Yes sir.

A. And which in high water are completely overflowed?

A. Yes sir.

Q. Would they operate in any way as septic tanks?

A. Yes sir, they could.

Q. Do you know as a matter of fact whether they do or not?

A. Well, not from my own personal study.

Q. How many cross-sections of the Illinois River, did you ever take in the course of this investigation?

2301 A. Well, we took cross-sections in 1901, in October and November, we took various cross-sections in the Illinois River.

Q. Did you take any in March of 1901?

A. No sir.

Q. Do you recall how many cross-sections you took in 1901, and where they were?

A. Yes, I took cross-sections at Joliet and took cross-sections at Peoria, at Wesley, between Peoria and Pekin, and took cross-sections at Pekin.

Q. How many did you take altogether?

A. Well, for the Illinois River there were four or five; I couldn't tell just now. I believe five, it may be four, but I am not sure.

MR. TODD: At what point, doctor?

A. At Joliet and then at points below Peoria and Pekin.

Q. MR. JOHNS: In taking cross-sections how many samples did you take?

A. We took one at Kingston, Illinois, which is eight miles below Pekin.

Q. In making the cross-sections of the Illinois River, how many samples did you take?

A. Well the cross-sections taken at Pekin and Peoria represented three sections across the river; that is, we took 2302 the center of the river and then the right and left shore coming down the river.

Q. Only taking three samples for a cross-section?

A. Yes sir, right there.

Q. Now have you presented anywhere the result of the analyses of these cross-sections?

A. No sir, they have not been presented as yet.

Q. There is no chart or table of these cross-sections in your testimony?

A. Well, thus far they have not been testified to.

Q. Have you referred in your testimony thus far, to any chart or table in which the result of the analyses of these cross-sections was made?

A. I believe in stating the amount of work that was done in the beginning of my testimony, I mentioned that I had taken cross-sections at these points.

Q. I asked you if you had stated anywhere the results of the analyses of the samples taken in these cross-sections?

A. No sir.

Q. Do you know how in any way of the stages of the Missouri, Mississippi and the Illinois Rivers from August, 1899 to January 22,1900?

A. Yes sir.

Q. Were they high or low?

2303 A. You mean from August, 1899, to January, 1900?

Q. Yes.

A. The stages of the rivers at what points?

Q. Any point?

A. They were comparatively low.

Q. Can you state what was the average stage of the river in feet as indicated upon the guages during that period?

A. I cannot tell without consulting data.

Q. Well, have you introduced any evidence or have you spoken about or referred to such data here in the course of your testimony?

A. Yes sir.

Q. Have you with you, or presented here the chart 1?

A. Yes sir.

Q. Or table 1?

A. Yes sir.

Q. I would like to see it.

A. Do you mean the chart or the table?

Q. I would like to see the table, but I would like to have both.

A. (Handing paper to counsel) That is the table of the data for 1899, compared with the Illinois and Mississippi Rivers at Grafton.

2304 Q. Now in your table, the one intitled on the left-hand side: "Location, Illinois River above Grafton; Mississippi River above Grafton," and below the table the words "Above table gives the average results of samples between September 6th, 1899, and January 17, 1900." You may state whether or not you have a table of the daily results of these analyses at those points during that time.

A. There were no daily samples collected during that period?

Q. Have you a table of the results of the analyses of such samples as were taken?

A. Yes, I have them all on record, on record sheets.

Q. Have you presented in any table that you have produced here, while you were testifying, such results as to each sample taken at those places during that time?

A. To my recollection, such record has not been presented, but I have them ready though—

MR. JOHNS: We would like to have that, General Crow.

GENERAL CROW: At what point, Grafton?

MR. JOHNS: I want the table showing the results of the analyses of each sample at that place at this time. We don't understand that table has ever been given.

Q. How many samples did you take from that time, September 6th, 1899, to January 17th, 1900?

A. Well, I don't recollect just now; there were quite a 2305 number; I believe there were some 19 samples from each one of those points at the mouth of the Illinois River. I will have to look that up.

PROF. KEISER: There were eighteen.

THE WITNESS: There were eighteen samples taken.

MR. JOHNS: Have you the dates upon which they were taken and the places from which they were taken?

A. Yes, I have them all on the record sheet.

Q. From what source did you obtain the statement that in round numbers there were only 800,000 population of Chicago which discharged its sewage into the Illinois and Michigan Canal?

A. To my recollection, I didn't state that 800,000 population discharged into the Illinois and Michigan Canal, perhaps you mean the Drainage Canal.

Q. I am going to ask you about that afterwards. From what source then did you obtain the information that only 800,000 people discharged sewage into the Drainage Canal?

A. Well, that information I obtained from statistics obtained from Mr. Benezette Williams, Civil Engineer.

Q. And the basis of 800,000 population is on Williams' statement or report?

A. Why, both his statement in the testimony here, as well as his report.

GENERAL CROW: Let me ask the witness a question. 2306 Now are you testifying here that Benezette Williams in his testimony here stated that only 800,000 of the Chicago population drained into the Drainage Canal?

A. No, I drew the conclusion from Mr. Benezette Williams

statement that at times, not all the time, only 800,000 population of the City of Chicago, were draining their sewage into the south branch of the Chicago River which sewage, when the weather was clear and there was no heavy rainfall, at such times when the sewage in the North Branch and in the South Fork of the South Branch was stagnated. At such times I said directly at the rate of 250,000 cubic feet per minute, the rate of flow passing through the Chicago River, that is the south branch of the Chicago River into the Drainage Canal. I said at that time the districts of Chicago that drained into the south branch of the Chicago River and directly into the canal through the south branch, I say that this district represented a population of 800,000 and this estimate at such times, I said, not all times, I very distinctly specified that at such times, that the figure was 800,000 population according to data presented by Mr. Benezette Williams. I then also stated that at times when there were heavy rain-falls and storm water coming down the North Branch and coming down the South Fork, that then at such times the drainage of sewage into the Drainage Canal was vastly
2307 larger, vastly increased, and that evidently at that time a much larger population was draining sewage directly into the Drainage Canal.

MR. JOHNS: I must remind you once more, doctor, you are here to answer questions and not at this time to indulge in discussion.

A. I beg pardon, I just wanted to explain my statement.

Q. Well, we will get that into the record, and that question asked by me, and the question asked by Mr. Crow, and the answers to those questions were all that was expected.

Q. Now you were in chicago in September, 1900?

A. Yes sir.

Q. You say that the Drainage Canal was practically closed during that month?

A. It was closed a number of days in the month of September.

Q. Entirely closed?

A. During the day time, yes sir. There were repairs at the dams there, and the regulations in the rivers, with improvements made in the Des Plaines river that necessitated, as I was told, the closing of the Bear Trap dam.

Q. I am asking you whether you know or whether this is something that was told you by somebody?

A. No, I was there myself.

Q. Did you see the Drainage Canal closed, so that no 2308 water from it flowed into the Des Plaines River?

A. Yes sir.

Q. In September, 1900?

A. Yes sir, I saw that myself at the Bear Trap dam.

Q. How often did you see that during September?

A. I saw that on three different days.

Q. Have you any memoranda by which you can tell what days they were?

A. I believe I could follow it up from some notes which I took at that time, and designate the days. I cannot just now.

Q. You haven't them with you?

A. No sir.

Q. Now you stated that there were fish killed there, dead fish in the Des Plaines River and the Illinois River at Joliet. Did you ever see any such thing?

A. No I didn't see any fish coming over dead, but it was reported to me by one of my water collectors and one of my assistants, who was up there after I was up there, that they had seen these dead fish coming over there.

Q. Who were they?

A. George Ottens, one of the water collectors, and Alexander Miller, a chemist who recently testified.

Q. What you know about it is what has been told you by somebody?

2309 A. Yes sir.

Q. You don't pretend that you have any personal knowledge of it?

A. No sir, they saw that. They went there after I had left.

Q. From what source did you get the information that only 47 per cent of the population of Peoria discharged its sewage into the Illinois River?

A. Well now, that I found in a report published by Mr. Harman Civil Engineer, in the Illinois State Board of Health Report of 1900.

Q. You don't know that by any personal examination whatever?

A. No sir.

Q. Do you know that at Peoria there are a number of large distilleries?

A. Yes sir.

Q. And very large glucose works?

A. Yes sir.

Q. And that there are a great many other manufactories in the city of Peoria?

A. Yes sir.

Q. Do you know that in these distilleries a very large number of cattle are fed?

Yes sir.

2310 Q. And that the sewage from this city of Peoria, in proportion to its population is enormously large?

A. Yes, it is quite large.

Q. And very much disproportioned to the amount of the water supply as discharged from its sewers into the river?

A. Well, that I don't admit.

Q. Well, do you know that pollution in an enormous amount is dumped bodily into the Illinois River at Peoria, not through sewers at all, but just bodily into the river?

A. I know that quite an amount of sewage and refuse matter is dumped into the Illinois River at Peoria, between Peoria and Pekin.

Q. Very much disproportioned to its population?

A. That I do not admit. That is, its disproportion to the population.

Q. I want to know whether it is so or not?

A. Every large city that dumps its sewage into running waters has more or less of such refuse.

Q. But in proportion to its population, 56,000 say, the amount of solid matter dumped into the river not coming in through the sewers at all, is very largely out of proportion, very largely in excess of the population?

A. Well, if we draw approximate comparisons with a great many other cities that have similar manufacturing
2311 industries, I don't consider it very much out of proportion.

Q. But I am taking the suppositious cities upon which you chemists proceed, that the suppositious amount of water per day per individual. You know that the solid matter and sewage of the city of Peoria is very largely in excess of that supposition you made?

A. I don't think it is largely in excess.

Q. Will you say that it is not?

A. I don't think it is. It is not; that is my opinion.

Q. In your opinion is Peoria an average of cities of its size as far as the pollution of its water course is concerned?

A. Do you mean whether it is an average size of city?

Q. No. So far as the pollution gets into its water course is concerned, is it about the same as the average city of its size, or in other words has it the same averages as other cities of its size?

A. There may be cities that have no manufacturing industries of that kind and naturally the amount of refuse from such manufacturing establishments would be very small; but there are a great many cities that have in proportion to their population equally large industries, and it would not be justifiable for me to say that this refuse from sewage from the city of Peoria is out of all proportion in comparison with the population. 2312

Q. Well, have you any personal knowledge about it, is what I am trying to get at?

A. Yes, I have been in Peoria several times and studied these conditions myself.

Q. Did you ever see floating down the Illinois River islands of discharged animal matter, combined with straw, and find them sixteen and eighteen miles below Pekin, 25 or 30 miles below Peoria?

A. I haven't seen such but I have heard of so-called floating islands coming down the river there and being recognized by parties in the towns below Peoria, between Peoria and Beardstown.

Q. Now that is a very unusual state of affairs, isn't it?

A. I have seen some of those so-called little islands myself. I remember now, in the trips I made down that river on such occasions.

Q. Have you ever seen them going over the Copperas Creek dam?

A. No sir.

Q. Have you ever been in the estuary of the Illinois River called Spring Lake, fourteen miles below Pekin?

A. No sir.

Q. You never saw them in that?

A. No sir.

2313 Q. Now as to the actual character and amount of sewage of Peoria, you know nothing practically, of your own observation?

A. Well I have testified as to certain facts concerning the sewage of Peoria, and there are certain conditions of that sewage and certain conditions of the pollution of the Illinois River by sewage and manufacturing refuse in the city of Peoria that I am familiar with.

Q. If the sewage of Peoria will purify itself, if the dilution which it receives from the Illinois River, in a run of from 25 to 50 miles down the river, why will not the sewage of Chicago discharged at Lockport, purify itself in a run from Lockport to Peoria?

A. First of all, the sewage of Peoria cannot purify itself by such a run of from 25 to 30 miles under the conditions prevailing in the Illinois River. That is, the water of the Illinois River as it reaches Peoria not being sufficiently pure.

Q. That is to say that the waters of the Illinois River, when it receives the pollution of Peoria, is not in such a condition as to aid materially in reducing and purifying the Peoria sewage in addition to the burden which it already carries?

A. The water in the Illinois River as it reaches Peoria and passes down is confined to the current in the Illinois River.

Q. There is no water outside of the current?

2314 A. Oh yes, there is, but it is the current of the Illinois River that carries the water of the Illinois River down that river. The sewage from Peoria is discharged into the River near the shore. There is a different speed of the river in the channel from the speed along the shore. The character of the shore is proved to be from my personal observation, it is such and the chemical analyses demonstrate that fact, it is such that the sewage from Peoria—I speak now of the sewage as it enters the Illinois River from the sewers, does not reach the channel right away. It remains along the shore and since it has been established that the velocity of the river along the shore is always slower and different from the channel itself and there being quite a number of impediments there, the river makes certain curves between Peoria and Pekin, there is a considerable slackening of the speed of the river along the shore and this sewage from Peoria has a considerable time to perform certain initial purification processes along its route whereas in the channel the current is faster and this sewage from Peoria when it reaches the channel finally has remained for some time along the shore and has undergone certain processes of initial purification. The chemical analyses of cross-sections show that.

Q. It has been in the septic tank adjoining the current in the channel of the Illinois River?

2315 A. In a measure we can call that a septic tank.

Q. Now, if the waters of the Illinois River were potable when the sewage of Peoria was deposited in them, and if the waters of the Illinois River were of the same volume as they are now with the drainage canal open, would the sewage of Peoria purify itself in 25 or 30 or 50 miles?

A. Under the circumstances as I have described them and provided that the water of the Illinois River as it reaches Peoria would be pure, would be potable water, which it is not. and which according to all chemical records, it is not—

Q. Excuse me. Pay attention to my question. If the waters of the Illinois River were of the same volume that they are now that the Drainage Canal is open and were potable when they reached Peoria, and then received the sewage of Peoria, would they purify themselves in a run of from 25 to 50 miles?

MR. JEFFRIES: I object to that question and submit the witness was about to fairly answer that question.

MR. JOHNS: Answer the question Yes or No.

MR. JEFFRIES: He was fairly answering the question.

MR. DRENNAN: Let him answer it; I think he was going to do it; let him answer the question separately.

Q. (Question repeated)?

MR. JEFFRIES: We interpose an objection to the 2316 question because it is assuming a fact that is not proven and is not true.

MR. DRENNAN: It is asked with the understanding, and we assume that to be a fact, and whether it is a fact or not is a matter of dispute.

THE COMMISSIONER: Answer the question.

A. If that water, the Illinois River water, as it reached Peoria, would be pure, from the analytical data obtained, from the examination of samples of water collected between Peoria and Grafton, the conditions as described by me prevailing in the Illinois River between Peoria and Kingston, and through the lower towns there, these analytical data would demonstrate that chemically the effect of the pollution of the Illinois River by the Peoria sewage would not be noticeable.

MR. DRENNAN: Within that distance, he specified, or beyond that distance?

A. I previously said it would take from 25 to 50 miles for that sewage to disappear in the channel of the river, not to be noticeable in the channel of the river, the effect of it.

Q. (Question repeated.)

MR. DRENNAN: Answer yes or no.

A. I have answered it.

MR. JOHNS: Let me ask him a question. You are to as- 2317 sume that the waters of the Illinois River at Peoria are potable, and of the same volume as when the Drainage Canal waters flowed at that point, and at that point they receive the sewage of Peoria, would not those waters purify themselves so as to be again potable in a run of 25 or 50 miles, and I would like you to answer yes or no.

GENERAL CROW: If you can so answer it.

A. Whether that sewage would be purified or not, absolutely purified or not, that is a question I cannot answer, because, as I said, the water in the channel shows a different character from the water along the shore, and samples taken from the channel from 25 to 50 miles below Peoria do not show any more, chemically, the effect of the discharge of sewage of Peoria into the river. That don't preclude that the Peoria sewage may still be, partly, in a partly decomposed state along the shore.

not in the channel, and may still necessitate further purification before it could have disappeared, from the analytical results.

Q. Do you understand that you are testifying here as an expert?

A. Yes, sir.

Q. Do you understand that a lawyer has a right to put a supposititious question to you and that he is entitled to an answer to it?

2318 MR. JEFFRIES: I object to the question.

THE WITNESS: Well, that is not for me to determine.

MR JOHNS: You don't know that you have to answer the question?

A. Well, I have answered the question.

Q. I am asking you now if you understand your position as a witness here?

GENERAL CROW: I object to the question.

MR. JOHNS: Do you understand as an expert witness that an examining lawyer has a right to put to you a suppositious state of facts, and he has a right to require you to answer them?

GENERAL CROW: I object, for the reason that the question and even the answer as given does not tend to prove or disprove any issue in this case, and further that an attorney has no right whatever to instruct the witness as to his duties on the witness stand.

MR. JOHNS: I think in the absence of a Court an attorney has.

GENERAL CROW: That is a matter of opinion.

MR. JOHNS: Answer the question.

Q. (Question repeated.)

A. As I have stated before, a chemical analysis of the water taken from the channel 25 to 50 miles below, would 2319 not show any more the presence of the sewage from the city of Peoria, but that would not preclude the sewage from the city of Peoria still being in the river along the shore, undergoing its natural processes of gradual purification.

Q. Do you understand that as an expert witness upon the stand you are required to answer such supposititious questions as are put to you by an attorney?

A. Well, I am perfectly willing to answer the question if I am requested to do so by some authority. I have endeavored to give all the information that I possess on that subject embodied in the question.

Q. Assuming that the waters of the Illinois River when they reach Peoria, are potable, and of the same volume as when the Illinois Drainage Canal is discharged into them, and that at that point they receive the sewage of Peoria, would those waters become potable again in a run of from 25 to 50 miles? Answer that question.

A. I don't think they would; that is, potable in general.

Q. Would they become potable in a run of 75 miles under the same circumstances supposed in the previous question?

A. In a run of 75 miles?

Q. (Question repeated.)

A. That would depend very much upon the character of the sewage of the city of Peoria.

2320 Q. Knowing the sewage of the city of Peoria as you do, as intimately as you have become acquainted with it by chemical analyses, would it purify itself in 75 miles under the circumstances supposed in the second preceding question?

A. That would depend upon the character of the sewage as such. Depend very much upon whether it would contain pathogenic bacteria or not.

Q. You made a statement on March 17th, that the sewage entering the Illinois River from the city of Peoria, after running from 25 to 50 miles, would purify itself so as to remove the polluting effect of the Peoria sewage on the Illinois River?

A. I said chemically.

Q. Is it true or not that if the waters of the Illinois River were potable before they came to Peoria, that the sewage entering the Illinois River from the city of Peoria, would, after running from 25 to 50 miles, purify itself, so as to remove the polluting effect of the Peoria sewage?

A. I said chemically, yes. I didn't say that at that time, but it was understood, and if I had been asked the question I would have said so at that time, that a chemical examination of the samples of water taken at a point below Peoria, and taking into consideration the general conditions of the river, I would say that that sewage disappears from the channel, that is, the

chemical result would not show its presence in the
2321 channel.

Q. 25 to 50 miles below Peoria, do you think it would show its presence along the sides of the channel?

A. The cross-sections that we have taken from the Illinois River below Peoria show chemically a difference between the water running along the shore and running in the channel.

Q. Answer this question. I have just as much time as you have. Does it show in the Illinois River on the sides, or would it show, and not in the channel 25 to 50 miles below Peoria?

A. At that distance?

Q. Yes?

A. That I couldn't tell, because I haven't made any examination of samples from that point.

Q. And you haven't produced the cross-sections to show it here, yet, have you?

A. The chemical researches demonstrate—

Q. Answer the question?

A. (Continued)—that sewage can remain on the shore for a long time before it goes down the river.

Q. You haven't produced the cross-section analyses of the cross-sections which show any such results here, have you?

2322 A. I have not. I have not been requested to do so.

Adjourned until 2:00 p. m., same day, March 30, 1903.

2323 Southern Hotel, St. Louis, Missouri, 2: p. m., Monday, March 30, 1903. Continuation after recess.

Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN, resumed the stand for further cross-examination, by Mr. Johns, and testified as follows:

Q. Were the samples of water which you took from the Illinois River taken all within the channel?

A. Yes, sir; the orders issued to the collectors were that they should always take them from the channel.

Q. When you took samples at the Chain of Rocks, on the Missouri shore, how far was that sample taken from the Intake?

A. That sample was taken as close to the Missouri shore as was necessary to get a characteristic sample of the Missouri River water as it hugged the Missouri shore.

Q. Your theory is that the Missouri River water at St. Louis coming down six or seven miles, is not mixed with the Mississippi River water to any great extent?

A. Well, that part of the River which runs close to the Missouri shore is composed principally of Missouri River water.

2324 Q. Now, the Missouri River comes into the Mississippi pretty nearly at right angles, does it not?

A. Well, that depends upon the volume of water coming down the Missouri River.

Q. In the mean stage of the Missouri River, its general geographical formation at its mouth, isn't it true that the current of the Missouri comes into the Mississippi at nearly right angles?

A. No, sir, that has not been my observation at such times when I was up there at the mouth.

Q. Well, if a man should look at a map, an accurate map of the Missouri where it enters the Mississippi, he would find that it comes in there at pretty close to right angles, would he not?

A. Well, you see the pressure of the volume of water coming down the Mississippi River will naturally produce a curve there; it would not turn down in such a way as to enable an angle to be formed.

Q. When the current of the Missouri River strikes the current of the Mississippi River, is it, or is it not about at right angles?

A. No, sir—no, it is not at right angles, because the pressure from the Mississippi River water will always produce a curve there.

2325 Q. Well, I will get to the deflection after a while. But run a line two miles up the current of the Missouri River and a line in the current of the Mississippi River at their junction—at the junction of the two, what would the angle be?

A. Well, that would be a different proposition.

Q. Well, that is the proposition that you are confronting now.

A. Yes, sir; that would produce an angle.

Q. Produce pretty close to a right angle, wouldn't it?

A. Yes, sir.

Q. Now, then, your theory is that when the two conflicting currents meet, the Mississippi overcomes the Missouri and turns it down the Missouri bank?

A. That depends upon the volume of water in each river. If the Mississippi is higher, it will naturally crowd the Missouri River current closer towards the Missouri shore. If the Missouri River is higher it will crowd the Mississippi River closer to the Illinois shore.

Q. Well, when there are equal stages of water, and in an average condition, your theory is that the current of the Mississippi overcomes the current of the Missouri and turns it down the Missouri shore, towards St. Louis?

A. No, not exactly; it don't turn it over to the shore so
that the Mississippi River would prevail. The two cur-
2326 rents will run alongside of each other, each river hugging
one shore—the Missouri hugging the Missouri shore, and
the Mississippi River hugging the Illinois shore. Now, it will
depend entirely upon the volume of water in each of those cur-
rents which will prevail in the channel—of the channel water.

Q. Well, when the stages of the river are equal, the fact is that the current of the Mississippi overcomes the current of the Missouri and turns it down at right angles, and runs it along the Missouri shore?

A. Well, what was the question in that connection?

Q. Well, that is the question. Is that the fact?

A. That they run alongside of each other on such occasions?

Q. Yes.

A. Yes, that can happen.

Q. Well, it does happen, does it not?

A. Yes, sir.

Q. But at the same time there is more or less a mixture of each of the rivers on the Missouri shore at St. Louis, at the Chain of Rocks?

A. Sometimes this mixture which may be found in the channel may crowd over toward the Missouri shore somewhat, but still our analytical data show that samples taken close to the Missouri shore will always be prevailingly Missouri River water—if close to the Missouri shore.

2327 Q. Now, the Illinois River comes into the Mississippi at a very slight angle, does it not?

A. The Illinois and the Mississippi?

Q. Yes.

A. Well, before they meet there is a long narrow strip of land that divides them, and when they meet they run almost parallel; that is, they come togeher slowly, this way (indicating).

Q. The Illinois River water keeps close to the Illinois shore?

A. Yes, sir, it is entirely a different situation than that at the mouth of the Missouri.

Q. Yes, the Illinois River keeps close to the Illinois shore, and the Mississippi River in its natural channel, closer to the Missouri shore?

A. Yes.

Q. How far is it from the Missouri shore to the place where you actually took the samples at the Chain of Rocks on the Missouri shore?

A. You mean how far from the Missouri shore to the—

Q. Place where you actually took the samples?

A. Well, that might have been 500 feet; it might have been 1,000 feet. It was left very much to the judgment of the collector who was to get the water from the particular current of the river as it flowed along there. When he was 2328 to get a sample of water from the Missouri shore, he was supposed to get Missouri River water, and when he was to get a sample from the Illinois shore, he was to get a sample of the mixture of the Mississippi and the Illinois Rivers as they ran along the shore of Illinois.

Q. There was then, as to the Missouri shore, no fixed and certain place at which the sample was taken?

A. No, sir; it depended upon the current entirely.

Q. And it was left to the judgment of the man who took the sample as to where he should take it?

A. Yes, sir.

Q. So that a sample one day might have been taken 300 feet from the Missouri bank, and the next day 1,000 feet from the Missouri bank?

A. Yes, sir, if the current would run that way; he was instructed to get samples accordingly.

Q. Is the current of the Missouri at the Chain of Rocks on the Missouri shore constant and regular?

A. Yes, sir.

Q. And flows along from day to day in about the same place?

A. Well, it varies somewhat in volume and in the width of the current at that place, but there is always some Missouri River water running close to the Missouri shore. Our analytical data show that. 2329

Q. So, if you took a sample of Missouri shore water, and upon the same day made a cross-section of the Mississippi and took one at the Intake and one at the Illinois shore, and you did the same thing the next day, you couldn't tell to save your life whether the sample on the Missouri shore was taken at or very near the place it was taken the day preceding, could you?

A. Well, we could tell from the comparison with the Bellefontaine samples, whether it was Missouri River water or not, that he got at the Missouri shore.

Q. Yes, after analyzation—but could you tell when the sample came into your office, or did you have any certainty of its being from comparatively or substantially the same place on the Missouri shore that it was taken the day before?

A. Well, for the most part of the year the Missouri River sample would always show more sediment and we could tell at a glance from the amount of sediment in the sample whether it was taken close to the shore or not, because the Missouri River always has a sediment.

Q. When you got a sample of Missouri River water on two succeeding days, could you tell whether they were taken from substantially the same place, or whether they might have been taken at a distance of five or six hundred feet from each other?

2330 A. Well, the chemist that would get those samples day after day would pretty soon be able to see those differences if there were any, and he could tell at a glance that must be water coming from the Missouri shore, because of its heavier sediment—heavier as compared with the Illinois shore.

Q. I am not asking you as to the amount of sediment, nor the analyzing, but from the mere fact that the sample was presented at your office on two successive days, purporting to come from the Missouri shore, could you tell whether they were taken within 500 feet of each other or not?

A. Well, sometimes I could.

Q. In what way?

A. Well, because the Missouri River current would come down the Missouri shore, and the Mississippi and Illinois mixture would come along the Illinois shore. Now, we could tell from the stages of the rivers in looking over the weather maps, we could see which river was higher, whether there had been a change in the stage of the river over night, and that would give us a line on the proximity of the Missouri River toward the shore.

Q. You could tell by the analyzing of a sample as to whether it was Missouri River water or not—largely? Whether it was a large per cent. Missouri River water?

A. Yes, sir.

2331 Q. Could you tell by the analyzing of a sample whether it was taken within six hundred feet of the sample of the day before which you analyzed?

A. Yes, I could by comparing it with the Missouri River sample taken at Fort Bellefontaine.

Q. And you could tell whether it was Missouri River water or not?

A. Yes, by comparing those two samples.

Q. But could you tell by the analysis whether it was taken within three hundred feet of the Missouri shore line or whether it was taken from about nine hundred feet from the Missouri shore line?

A. Well, not from the analytical data alone.

Q. Well, now, how far is it from the Chain of Rocks to the place where you took the water from the Illinois shore?

A. Well, that varied. It might have been 75 yards—

Q. From the Chain of Rocks—from the Intake at the Chain of Rocks?

A. Oh, you mean from the Intake?

Q. Yes.

A. Yes, even from the Intake. Of course the stage of the River would have a great deal to do with the width of the river at that point. Sometimes the water would be high of course, and the Illinois and Mississippi River mixture would 2332 prevail of course, considerably if it—if a large volume of water came down the Mississippi. It wasn't necessary then for the collector to go very close to the Illinois shore.

Q. Now, from any place on the side of the river designated as the Illinois shore, where you took samples each day?

A. Well, originally I went out and took the collectors out there and told them just about in this neighborhood here (indicating) you ought to take the samples, but you have got to follow your own judgment very much in connection with the stages of the river. Just see that you get the sample that is most characteristic of the water running along that shore.

Q. It was not an endeavor then to take water at any particular and certain point on the Illinois shore, but it was an endeavor to leave it to the judgment of the collector to select the place in which he would get water characteristic of the Illinois shore?

A. Well, he was originally instructed to get it at certain points selected by me, and to always try to get them as close to that point as possible.

Q. Now, was that instruction followed?

A. Yes, sir.

Q. Was the sample from the Illinois shore then taken substantially at the same place each time?

2333 A. Oh, no, I can't say that exactly from the same place, but about in that neighborhood there. You see the samples were taken from a skiff, and the skiff floats while the samples are taken, and it cannot be a fixed point. Simply the instructions can only designate "In this neighborhood, right around here, as close to this place now where I am today, you ought to collect samples hereafter."

Q. How close were you to the Illinois shore when you told the man this was to be the place that you wanted to take the Illinois shore sample?

A. Well, that day, I was about 75 yards I think—I remember.

Q. From the Illinois shore?

A. Yes, sir.

Q. And opposite the Chain of Rocks?

A. Yes, sir.

Q. Now, do you suppose for a moment that the water at that point, any of it, ever got into the Intake Tower?

A. When I took the sample on that—or when I designated those points on the certain days, I believe the Missouri River at that time on that day prevailed at the Intake, but I am not quite sure about that; I would have to look up the data.

Q. Well, I will have to ask you the question again. Do you suppose that any of the water which you took at the place which is designated as the Illinois shore, ever got into the Intake? 2334

A. Yes, it got into the Intake quite frequently.

Q. How did it do it?

A. Well, when the Missouri River was low, and the larger volume of the Mississippi River water coming down the Illinois shore, would push the Missouri River toward the Missouri shore, and beyond the Intake, which is 1,500 feet distant from the Missouri shore line, and on such days, the Mississippi and Illinois mixture water would get into the Intake.

Q. Now, let us see if we can understand each other. The water taken at the place called the Missouri shore at the Chain of Rocks, and the Intake at the Chain of Rocks, and the Illinois shore at the Chain of Rocks were supposed to a cross-section of the Mississippi?

A. Yes.

Q. And the point on the Illinois shore was opposite the Chain of Rocks?

A. Yes, sir.

Q. Is that correct?

A. Now, what is the question?

Q. The point on the Illinois shore opposite the Chain of Rocks, and the point at the Intake Tower and the point which you designate as the Missouri shore, constituted a cross-section of the Mississippi River? 2335

A. They were to constitute a cross-section as near as possible.

Q. Then the point designated as the Illinois shore was opposite the Chain of Rocks and near the Illinois shore?

A. Yes, sir.

Q. Now, the question is, did any drop of the water from that point designated as the Chain of Rocks, as the Illinois shore, ever get into the Intake, and if so, how?

A. Of course, from that collection point on such a day the water that would flow along the Illinois shore would only get into the Intake, if out in the channel, upon the edge of which channel the Intake Tower is located. If in that channel, Mississippi River water would prevail, then that Mississippi River water would go into the Intake.

Q. That assumes that the water on the Missouri side of the Mississippi channel is the same as the water on the Illinois shore outside of the Mississippi channel?

A. No, sir; because the line of demarkation between the Missouri River current and between the Mississippi River current on such days might have been between the Missouri shore and the Intake, so that the Intake was getting Mississippi River water, while beyond the line of demarkation between the
2336 two currents the Missouri shore was getting Missouri River water, the Intake being located 1500 feet from the Missouri shore on the edge of the channel.

Q. If the Intake is on the Missouri side of the Mississippi channel, and the point designated as the Illinois shore is on the Illinois shore side of the Mississippi channel, then all your calculations assume that the water between the Intake and the Illinois shore points is precisely the same as the Illinois shore points, is it not?

A. You say that the water was taken between the Intake Tower and the Illinois shore—

Q. Is precisely the same?

A. Between?

Q. Yes, all your calculations are based on that assumption?

A. I know, yes, but that depends again upon the percentage of mixture of the two rivers in the channel.

Q. That is precisely what I am getting at.

A. You see the Intake Tower being located on the western edge of the channel, there might be a different water in the channel then 20 or 30 feet east of the Intake Tower, and still a different kind of water chemically, running along the Illinois shore.

Q. Well, why do you in determining the percentage of Illinois water, of impurities from the Illinois River at the
2337 Intake, use as one of the elements of the calculation the water on the Illinois shore?

A. Because the samples taken from the Illinois shore were such samples as would be most characteristic of the water running along that shore.

Q. Well, the water at the Illinois shore at the point, at the Chain of Rocks, and at the point from which you took it, never did get ito the Intake, did it?

A. Now, how is that question, please?

Q. The water at the point where you attempted to take, at the Illinois shore —

A. Yes.

Q. That water never did get into the Intake, did it?

A. It could not on such days because the point of collection was to be far enough away from the Intake so that it should not be water that was going into the Intake, but should be water that was passing along the Illinois shore.

Q. If you took a sample of water on the Illinois shore opposite the Intake, the water at that point in order to get into the Intake of the St. Louis Waterworks, would have to turn a direct right angle and travel across the stream, wouldn't it?

A. Yes, sir.

Q. Now, did that ever occur?

A. Not to my knowledge.

2338 Q. Then when you assume in calculating the per cent. of pollution, nitrites, nitrates, free ammonia, albuminoid ammonia, or anything, upon the basis of such pollution at the point known as the Illinois shore, the Intake and the Missouri shore, you never did get it right, did you?

A. I can't draw that conclusion at all, from my statements.

Q. If none of the water at the point where you took it, could by any possibility, get into the Intake Tower, then all your entire basis of calculation was wrong, wasn't it?

A. I said that the instructions to the collectors were such that he should take a sample of the water running along the Illinois shore and not that water that was going into the Intake, because he was to take a separate sample at the Intake to find out the character of the water that was going into the Intake.

Q. Well, your idea of taking water at the Illinois shore was to get the condition of the water at the point where you took the sample, was it not?

A. Yes, sir.

Q. Now, if that point was a direct line, and immediately opposite the Intake Tower, the condition of that water never was represented at the Intake Tower at all, was it?

A. No, sir; the character of the water taken from the Intake Tower was represented in another sample taken
2339 right at the Intake tower where the water flows in there.

Q. But the water which was taken at the point called the Illinois shore, opposite the Chain of Rocks, was never the water which entered into your calculations as to the mixture of the Mississippi and the Illinois at the Intake Tower, was it?

A. Oh, it entered into the calculations when I made certain calculations to estimate the percentage of the mixture of the waters at the Intake Tower.

Q. The figures derived from the analyses of the water on the Illinois shore entered into your calculations as to the character of the water at the Intake Tower, did they not?

A. No, sir; it could not, because it was a different water. It was not water going into the Intake Tower unless the Mississippi River should be so high that it would push the Missouri River toward the Missouri shore and prevail in the narrow channel, and thus get into the Intake.

Q. Supposing a case—take a piece of paper—suppose the nitrites at the point known as the Illinois shore were .007, and the nitrites at the Intake Tower were .005, and the nitrites at the point known as the Missouri shore were .003—what percentage of the waters of the Mississippi River enter the Intake?

2340 A. Well, now, I don't base the calculation in my testimony on the nitrites as found on those three shores—at those three points.

Q. Well, I am asking you to do it now?

A. Because I consider the margins so very small there that the data would be approximations, whereas, if I would take the total solids found I might get larger variations and consequently better results. I mean results—get more detailed percentages.

Q. I am not anxious at all now about the results. That is one of the least of my troubles. The question is if the nitrites were as supposed there, you being bound by the supposition, wise or foolish, what was the per cent. of Mississippi River water, as indicated by nitrites, going into the Intake Tower?

A. Well, I would say that the water going into the Intake is a medium there, between the water at the Illinois shore and the Missouri shore, but I don't calculate any per centages on that basis.

Q. Can you calculate a percentage on that basis?

A. Yes, I think it can be done.

Q. Take your chart 8, for instance, and tell me whether or
not you base your calculation as to the per cent. of chlo-
2341 rine at the Intake Tower upon the 23rd day of January,
upon the data which that table or chart shows?

A. Yes, based upon the chlorines there I made an approximate estimate there, and an approximate average of the percentages as found at the Missouri shore, Illinois shore and the Intake Tower.

Q. At the Chain of Rocks?

A. At the Chain of Rocks, yes.

Q. Now, the chlorine is not very different from nitrites in their ability to turn a right angle and come across from the Illinois shore to the Intake Tower, are they?

A. Well, that depends very much upon the general relation of the various chemical ingredients there. I would not say that they run parallel, the chlorines and the nitrites.

Q. Now, but I am asking about the ability of the chlorines to turn a right angle at the point called the Illinois shore, and run into the Intake Tower?

A. Well, now, that is hard to tell. My observations do not enable me to say so.

Q. Well, don't you know of course that it is a physical impossibility; that they couldn't do it?

A. Well, I have said, to my knowledge, I didn't know. I don't want to assert anything I don't know.

2342 Q. Well, theoretically now, chemically considered, do the waters at the point called the Illinois shore turn a right angle and make a straight shoot for the Intake Tower?

A. No, sir; as I said before, I said there is no—I have never seen from my own observation any right angle there.

Q. Now, what point up the Mississippi River do you think that it would be fair to select in order to get a sample of Mississippi River water which actually intermingled with the Missouri and went into the Intake Tower?

A. I consider one mile above the mouth of the Missouri River in the Mississippi as a proper point.

Q. Proper point?

A. Yes, sir.

Q. Well, then your calculations as to the pollution of the waters of St. Louis having been based entirely on the samples taken at the Illinois shore, are upon a false basis, are they not?

MR. WOERNER: I object to the question on the ground that it assumes that the witness has stated that the water on the Illinois shore at that point passes into the Intake, whereas, the testimony of the witness has been that samples were taken on the Missouri shore so as to get the characteristic Missouri water, and on the Illinois shore so as to get the characteristic Illinois water, and comparing the same with the water taken from the Intake, to be able to ascertain how much of a 2343 mixture of those two waters passes into the Intake.

Q. Well, answer the question.

A. What is the question?

Q. (Question repeated.)

A. Well, I have taken for comparison—

Q. No, answer the question; they are or they are not on a false basis?

MR. WOERNER: One moment. I further object to the question on the ground that it assumes that the witness bases his calculations solely upon the water taken from the Illinois shore, whereas, such is not the case. I don't think your question is fair.

MR. JOHNS: Well, I am responsible for that. You needn't worry about it.

Q. Answer the question?

A. Now, do you refer to this approximation of chlorines at the Intake Tower, or do you refer to my general percentages of total solids, as found in the Missouri River and the Mississippi above the mouth of the Missouri, and the Intake. There are two different kinds of estimates that I have made there?

Q. (Question repeated.)

A. I cannot say that they are on a false basis because they have not been compared in such a way.

Q. Where did you obtain the data upon which you base
2344 the calculation made as to the percentage of Mississippi
River water and the Missouri River water entering the Intake Tower?

A. One sample was taken from the Missouri River at Fort Bellefontaine; another sample taken from the Mississippi River from the channel of the Mississippi River one mile above the mouth of the Missouri at a point designated as Hartford in the analytical records, and on the charts; the third sample was taken from the collection point at the Intake Tower; that is the water as it flows into the Intake Tower was sampled, and the samples from these three points were compared. The residue on evaporation was selected as affording the widest range in figures, and therefore the closest approximate estimate of percentages of mixtures at the Intake.

Q. Well, in that calculation you have no reference to the Illinois shore, at all—at the point called the Illinois shore?

A. No, I have taken the channel water.

Q. From the Mississippi?

A. From the Mississippi one mile above the mouth of the Missouri.

Q. Now, what per cent. of that water was water from the Illinois River you don't pretend to know, do you?

A. How do you mean?

Q. What per cent. or what proportion of the water taken
2345 in the channel of the Mississippi River at Hartford was
of the entire water, in the Mississippi River at that point you don't pretend to know?

A. Well, I only know that it was the water that was running in the channel; the water that was coming down.

Q. Well, there wasn't any of it Illinois River water—do you know?

A. Well, the analysis of the channel water showed that there is Illinois River water in that mixture that runs in the channel.

Q. I am asking you as a matter of fact, do you know whether any water taken at Hartford in the channel of the Mississippi River is a mixture of the Illinois river water with the waters of the Mississippi, above its mouth?

A. Yes.

Q. How do you know it?

A. From analytical data that I have.

Q. Do you know it in any other way than that?

A. Well, at times of personal inspection of those points I know that those samples were taken from the channel.

Q. Yes, but how do you know that those samples contained any Illinois River water by inspection?

A. Well, by inspection alone I could not ascertain that chemically that water was a mixture, it required the 2346 chemical analysis subsequently made to determine that Illinois River water was contained in the mixture running in the channel.

Q. If the nitrites on any given day at Hartford in the channel of the Mississippi were .004 parts per million, what percentage of that was Illinois River water?

A. That I could not tell off hand. I could study the analytical data and the original figures, and draw deductions therefrom.

Q. Are your figures based then upon the assumption that the waters of the Illinois River and the Mississippi River at Hartford are thoroughly mixed?

A. I am of the opinion that the chemical analyses prove that the water running in the channel between Grafton and the mouth of the Missouri, is a mixture of Mississippi water above the mouth of the Illinois River, and Illinois River water; that after they meet they mix; the analytical results demonstrate that.

Q. But the waters of the Mississippi and the Missouri do not?

A. The waters of the Mississippi and the Missouri also mix. The analyses of samples taken from the Mississippi River channel after the two rivers meet demonstrate that.

Q. That they do mix?

A. Yes, sir.

Q. Well, are the waters of the Mississippi River in the
2347 channel at Hartford a complete mixture of the waters of
the Mississippi above Grafton, and of the waters of the Illinois River as they come in at Grafton?

A. It would be impossible to say complete, but the mixture is proven by the chemical analyses of samples from the channel.

Q. It is proven that there is some mixture?

A. Yes, sir.

Q. So far as mere matter of mixture is concerned?

A. Varying more or less from day to day.

Q. Well, now, are they mixed more at Hartford than they are at the Chain of Rocks?

A. Now, you mean to say that the Illinois River and the Mississippi River water there are better mixed at Hartford than they are at the Chain of Rocks?

Q. Yes?

A. Well, that would be difficult to establish because the water in the channel at the Chain of Rocks also contains the Missouri River water, and that would be the mixture of three rivers and it would be difficult to estimate.

Q. Are the waters of the Mississippi River above Grafton, and the waters of the Illinois River as they come into the Mississippi at Grafton, better mixed at Hartford with each other than they are at the Chain of Rocks?

2348 A. Well, that is a question that cannot be answered. I couldn't say so.

Q. Then on what theory did you take a sample at the point called the Illinois shore?

A. On the Illinois shore?

Q. Yes, opposite the Chain of Rocks?

A. Opposite the Chain of Rocks?

Q. Yes.

A. Because there is always a current running along the Illinois shore that is distinguishable in a chemical analysis from the current running along the Missouri shore and the channel water, the three are always different at the Chain of Rocks.

Q. And the sample taken at the Illinois shore is more representative of the Illinois River water, is it?

A. The sample taken from the Illinois shore demonstrates by its chemical character that it is a mixture of the Illinois River and the Mississippi River.

Q. Does it demonstrate that there is more of the Illinois River water in the mixture at the Chain of Rocks, than there is of the Mississippi?

A. Well, that would necessitate a very close study of the analytical data, it varies. The amount of mixture of those two rivers for each will vary constantly.

2349 Q. Was the object in taking the sample at the point called the Illinois shore opposite the chain of rocks, to get as good a representative of the Illinois River water as possible?

A. No, sir. The object was to get as good a sample as possible of the water running along the Illinois shore, because the analyses show that it differed from the water going into the Intake and from the water running along the Missouri shore.

Q. And it also showed that the water of the Illinois River predominated on the Illinois shore at a point opposite the Chain of Rocks, at which you took the sample?

A. Well, that, strictly speaking, would be impossible to say, but the Illinois River predominates on the Illinois shore; it is a mixture that runs along that shore of the Mississippi and the Illinois, and the water taken from the Illinois shore shows in its chemical results greater pollution and more impurities than the Mississippi River above the mouth of the Illinois River, so consequently the mixture of the Mississippi River and the Illinois River which takes place in the channel between Grafton and the mouth of the Missouri, that mixture continues and increased pollution continues to show in the water running along the Illinois shore at all times.

Q. And it shows also, doesn't it, that at a point opposite 2350 Chain of Rocks the characteristics chemically of the Illinois River predominate over the characteristics of the Mississippi River above Grafton?

A. I couldn't say predominates, but that pollution of the Mississippi River below the Illinois River shows its effect in increased figures of the characteristic ingredients of sewage found in the water at the Illinois shore, Chain of Rocks, as compared with the water found in the Mississippi River before it meets the Illinois. The effect of the pollution of the Mississippi River by the Illinois, can always be traced down to the point of collection in the Mississippi River from the Illinois shore at the Chain of Rocks.

Q. The per cent. of pollution in the water at the point called the Illinois shore, opposite the Chain of Rocks, is higher than the per cent. of the pollution of the Mississippi River above Grafton?

A. Yes sir.

Q. The per cent. of pollution of the Mississippi River at Hartford in the channel is greater than the per cent. of pollution of the Missouri River at Bellefontaine?

A. Yes, sir.

Q. The per cent. of pollution at the Intake Tower is higher than the pollution shown in the Missouri River at Bellefontaine?

2351 A. At such times when the Mississippi River and the Illinois River mixture enters the Intake Tower, at such times, which frequently occurs, the water going into the Intake is more polluted than the water found in the Missouri River at Bellefontaine, but whenever the Missouri River is very high and it crowds the Mississippi River, the Illinois River mixture towards the Illinois shore, so that the Missouri prevails in the channel, then the water that flows from the channel into the Intake Tower is prevailingly Missouri River water, and the analytical results will show at such times that the water that goes into the Intake is chemically just like the water running along the Missouri shore and just like the water found in the sample taken at Bellefontaine, Missouri River. Then the three are alike. When the Missouri River prevails in the channel, Missouri River water goes into the Intake, but when the Missouri River is lower than the Mississippi and Illinois mixture and the latter prevails in the channel, the Intake Tower being located 1500 feet from the shore on the edge of that channel the

Intake Tower then gets the Mississippi and Illinois River mixtures, and the analytical results show that the water that goes into the intake then is more impure and more polluted than the water found on the Missouri shore in the Missouri River current, and found at Bellefontaine in the Missouri River.

2352 Q. If you find by analyses that the water going into the Intake Tower has a higher per cent. of pollution than the water of the Missouri River at Bellefontaine, your chemical conclusion is that the water going into the Intake Tower is very largely Mississippi River water?

A. Yes, sir.

Q. And your conclusion is based not upon any ability to observe by the currents, which river it is, but solely and entirely from the chemical analyses?

A. Yes sir.

Q. And is based not upon any personal observation of your own, but soley and entirely upon the chemical analyses?

A. Yes sir.

Q. Where did you get the data for the curve described upon chart 8?

A. Those data were obtained from analytical results which were calculated from chemical analyses of samples of water collected from January 23rd, until October 2nd, 1900, from the Missouri shore, the Chain of Rocks—from the Intake Tower at the Chain of Rocks, and from the Illinois shore at the Chain of Rocks.

Q. If you were going to make a table showing the relation between the respective quantities of Missouri and Mississippi River water pumped, why did you not take your data from 2353 Bellefontaine, the Mississippi River above Grafton, and the Illinois at Grafton?

A. Because the question as to the chemical character of the water going into the Intake could best be answered by taking a sample from the channel at Hartford, representing the Mississippi River water just before it meets the Missouri River.

Q. If that is the case, why did you take a sample of water at the Chain of Rocks and on the Illinois shore for comparison?

A. Because I considered that the most important question was in calculating out the daily results as we can see them from the chemical analyses, that we had better take the Missouri

River before it meets the Mississippi and the Mississippi before it meets the Missouri, so as to get the accurate character of those rivers, and since they each flow down the Mississippi River, each one hugging the shore, the Missouri the Missouri, and the Illinois and Mississippi mixture hugging the Illinois shore, that we would get the data that would best show the effect of the mixture of those rivers, taking those points.

Q. You took the data on the Illinois shore in that chart to determine what?

A. This chart was only to determine a general average for the whole period. Total residue on evaporation and 2354 chlorine and nitrites by comparison, but as regards the most accurate data in the table, I considered it largely a range of figures between the Missouri River sample and the Mississippi River sample above the mouth of the Missouri, as affording a more accurate and detailed estimate. The ranges are very wide there, the figures on total solids, and afford a very good estimation of those percentages. For the daily percentages, for the daily approximations, this estimate based at the Chain of Rocks would do, but between the two I would consider the percentage estimations from the samples taken in the Missouri River and the Mississippi above the mouth of the Missouri and the Intake, as more conclusive, particularly because they show the daily variations better.

Q. Then why, in order to determine the respective quantities of Missouri and Mississippi River water pumped, did you take a sample from the Illinois shore when you knew it was a physical impossibility for that water to be pumped at all?

A. Well, that is to show the character of the current running down the Mississippi River at the Chain of Rocks.

Q. It shows the character of the current on the Illinois shore, doesn't it?

A. Yes sir.

Q. And the character of the current at the Intake?

2355 A. Yes sir.

Q. Which is across the channel of the Mississippi from the point known as the Illinois shore?

A. Yes sir.

Q. And the character of the indefinite place known or styled the Missouri shore?

A. Yes sir.

Q. If no drop of the water taken at the Illinois shore as represented by the blue line on that chart ever entered the Intake tower, then that blue line is not a fair representation of the character of the Mississippi River water which was pumped into the Intake, is it?

A. Well, in order to get a percentage there, I also take the current of the Missouri River as it runs along the Missouri shore, and taking these two figures and taking the result of the analyses as found at the Intake, that would allow a fair approximation like this.

Q. Have you a chart, or did you ever exhibit a chart of the residue upon evaporation or the chlorine?

A. Yes sir.

Q. And the nitrites at Bellefontaine, Hartford and the Illinois River above Grafton.

A. No sir.

2356 Q. For what purpose was that chart 8 presented then?

A. This chart 8 was principally presented to show an approximate average for the entire period from January until October, 1900, of the residue on evaporation as found at those three points, the Illinois shore, the Missouri shore and the Intake at the Chain of Rocks, and also for the chlorines.

Q. Was it taken for the purpose of showing that the water at the Intake was in its chemical characteristics intermediate as to the Missouri River water, and the water of the Mississippi?

A. Well, it was to show whatever result might be ascertained by the chemical analyses of any mixture if there was any, and the conclusions from the results as found by these analyses demonstrated certain facts there that showed that there must be mixtures going on of the two rivers in the channel, which water goes into the Intake tower.

Q. And that is on the supposition that the water at the point on the Illinois shore opposite the Chain of Rocks, in its condition is taken, and enters the Intake?

A. Well, that water as it runs along the Illinois shore has certain chemical characteristics. It may be that when the water running along the Illinois shore, that is, the Mississippi and

Illinois River mixture is very high, it may be that the water prevailing then in the channel because of the crowding
2357 of this larger volume of the Mississippi and Illinois River mixture, the crowding of the Missouri towards the Missouri shore, may go on to such an extent as to prevail in the channel, and the samples then taken from the channel at the Intake may show the same chemical results such as are found from the samples running along the Illinois shore, so, while that sample of the water that was taken from a certain point on the Illinois shore would not go into the Intake, yet the current predominated, the current of the Illinois shore water predominated in the channel on that day, would give that other sample that is collected at the Intake the same chemical character as the sample would have, running along the Illinois shore, which would demonstrate that at such a time there is a larger percentage of Illinois and Mississippi River mixture going into the Intake.

MR. JOHNS: I now move that the answer be stricken out as not responsive to the question.

Q. Was that chart taken and made for the purpose of showing that the water at the Intake Tower was intermediate in its quality, as between the Missouri River and the water on the Illinois shore?

A. It was simply made for to show certain analytical resuluts.

Q. (Question repeated)?

A. In so far that the study of the analytical data proved that, yes.

2358 Q. Now take your chart No. 9, where did you get your data as to typhoid fever?

A. The data as to typhoid fever were obtained from the Health Department, the Health Commissioner's office of St. Louis.

Q. Out of what kind of a book or paper?

A. These data were obtained by one of my assistants and received by him from an official in the Health Commissioner's office who tabulates that.

Q. Do you know whether they were taken from reports, printed reports, or from records written?

A. My instructions were to take them from the official reports.

Q. Does the lower, very irregular curve upon this chart represent the percentage of Mississippi River water pumped into the Intake?

A. Yes sir.

Q. What do you mean there by percentage of Mississippi River water?

A. That is, I had the percentage of mixture of water of the Missouri River and the Mississippi above the mouth of the Missouri and the water going into the Intake. I had the percentages calculated from the total residue on evaporation, so-called total solids, and whatever the percentage of Mississippi River water, as compared with the percentage of Missouri River water so found, is represented on this chart here in the bottom curve. 2359

Q. That bottom curve then represents a supposed percentage of Mississippi River water, based on calculations of the Mississippi above Grafton?

A. No sir, I beg your pardon, the Mississippi above the mouth of the Missouri at Hartford.

Q. And the Missouri at what point?

A. Bellefontaine.

Q. Finding certain chemical constituents prevailing or existing in these two rivers at those points, you made a curve representing what you estimated to be the percentage of Mississippi River water, which is the lower curve on chart 9?

A. Yes sir.

Q. Now why did you not also make an estimate as to typhoid fever based upon the percentage of Missouri River water at the same time?

A. Well, because when I gave the percentage of Mississippi River water here, the remaining percentage or balance—supposing I gave, I will say—I have twenty per cent of Mississippi River water; that means that the remaining 80 per cent is Missouri River water. Thus you will see in these summer months the Missouri River water prevail largely, that the percentage of the Mississippi River water goes down to the zero point, which means that the Missouri River water prevailed entirely at the Intake at that time. 2360

Q. Can you explain why the typhoid fever in St. Louis did not visibly increase from the 20th of March to the 14th of August.

GENERAL CROW: In what year? 1900?

MR. JOHNS: Yes.

THE WITNESS: I will have to go back to the river stages of the Illinois and Mississippi Rivers above the mouth of the Illinois, to answer that question. During the months of February, 1900, after the opening of the Drainage Canal on January 17th, the Mississippi River above the mouth of the Illinois River was low. The data presented every day in my testimony there, reading the stages of the river, showed the Mississippi to be very low. At that time evidently, the volume of Mississippi River water which met the Illinois River was low, so that there was much more Illinois River water in that mixture coming down in February than there was after the rise of the upper Mississippi River above the mouth of the Illinois River in March, which I also showed. I showed a very marked rise of the Mississippi River water above the mouth of the Illinois,
2361 so that the Mississippi River water coming down in
March there—the Mississippi River water evidently had a much larger portion of Mississippi River water than Illinois River water and the Illinois River water being represented in a very small percentage of that time because of the larger volume of upper Mississippi water coming down. That water was entirely different in its chemical character from the water coming down in February. In February the upper Mississippi above the mouth of the Illinois was low. The water then represented in the mixture at the Intake—I want to say that evidently there was a larger percentage of Illinois River water, of that mixture going into the intake, in February and being represented by a high percentage, one day as high as 100 per cent, going down again and then going up again, in February up to 90 per cent; there was more Illinois River in that mixture; that was followed by a rise in typhoid for the month of March.

Q. Now why did the typhoid fall and the percentage of cases fall when the Mississippi River was at 100 per cent on the 27th, or in the middle of April?

A. Because then at that time the Mississippi River water had a different character than the Mississippi River water coming down in February, and it had a larger percentage of upper Mississippi River water and a smaller percentage of
2362 Illinois River water.

Q. So that the chart doesn't contain anything about the Illinois River, but simply assumes that when the typhoid fever is bad, the Illinois River water prevails.

A. From the stages of the river as officially recorded by the Weather Bureau, it is evident that the first big rise in February was due to the Mississippi River at that time, a rise in typhoid followed, a period when there was very much more Illinois River water in that mixture than there was subsequently when the second great rise or percentage of Mississippi river water came. The second great rise represented largely upper Mississippi River water above the mouth of the Illinois and the proportion being much larger than that of the Illinois River at that time, the Illinois River water was of necessity represented by a smaller percentage. That was not followed by typhoid in St. Louis, and that is what the map is to indicate.

Q. And that is what the map was made to show?

A. Well, the stages are not represented on this map, but if the stages would be on this chart they would show that.

Q. Now do you know the particulars or history of any case of typhoid fever in the city of St. Louis, prior to January 23rd, 1900?

A. Yes sir.

2363 Q. What one?

A. Well, you mean an incidental case?

Q. Any case of typhoid fever prior to 1900, in the city of St. Louis, the history of it and the ascribed cause of the disease?

A. I am not a physician, so of course I have no experience in that direction.

Q. Do you know the cause of any one or more cases of typhoid fever after 1900 in the city of St. Louis?

A. Well, I have given the matter considerable study.

Q. Answer the question. Do you know the cause of any one or more cases of typhoid fever in the city of St. Louis after 1900?

A. Well I have not treated any cases because I am not a physician.

Q. You either know or you do not. Which is it?

A. Well I am familiar with the history of quite a number of cases.

Q. Now for example, give me the history of one case?

A. Well, I cannot recall any particular one just now.

Q. Well, give me the history of three?

A. I cannot recollect, because these cases as I studied them were simply from information that I have received by coming in direct contact with physicians who treated the 2564 cases of typhoid fever, and from the study of reports and the study of books that were written on that subject.

Q. Do you know of a single case of typhoid fever in the city of St. Louis, in which you could tell the reason or the manner of the getting into his system of the typhoid bacillus. I mean now of your own personal knowledge?

A. Well, I have instituted an investigation to ascertain from the official data of reported cases of typhoid fever, and a personal inspection of every case during one year by inspectors who were instructed by me to examine the cases. I have ascertained that a large majority of cases of typhoid fever in St. Louis reported during one year after the opening of the canal, that these cases all correspond with the fact that the patient had been drinking city water during that period.

Q. That you got from the reports of inspectors employed by you?

A. From the official reports of the physicians when they reported their cases to the health department.

Q. Do the official reports of the city of St. Louis made by the physicians, state the cause of the disease?

A. Yes sir.

Q. And you say you have inspected those reports and find that in the majority of cases reported, that they have been drinking St. Louis water?

2365 A. They have been drinking water from the city water supply.

Q. Does it say anything about whether they had been drinking milk?

A. Yes, in some instances.

Q. How many people in the city of St. Louis get their water from the city water supply?

A. Well, I cannot give you an accurate figure just now as to that question, but by far the larger majority of the population have the city water supply.

Q. Three-quarters?

A. Well, I wouldn't say because I haven't got the accurate figures.

Q. One-half?

A. I would say the larger majority as I have been told by the officials of the water department, but I haven't got accurate figures.

Q. Personally you know nothing in regard to it?

A. No, I have no data on hand just now.

Q. How many cess-pools are there in the city of St. Louis?

A. Well, I don't believe that there is a record establishing just how many there are.

Q. How many wells are there in the city of St. Louis?

2366 A. The number of wells in the city of St. Louis, about four years ago, when I gave particular attention to that question probably amounted to from 3500 to 4000.

Q. Not more than that?

A. No sir. There are quite a number of cisterns in addition to that, so that we usually say there are 7000 cisterns and wells in the city of St. Louis.

Q. What proportion of those typhoid fever cases were suffered by people who took water from wells or cisterns?

A. It was ascertained in this special investigation, that of the 1160 or 1180 cases reported in 1900, of typhoid, three-fourths of these patients did not drink any well water or cistern water, but only drank water from the city supply.

Q. From the city water supply?

A. Yes sir. The others admitted that they drank well water, but frequently would also drink water from the water supply besides.

Q. In addition?

A. Yes, but those that drank nothing but city water amounted to 800 and something out of 1160 or 1180 cases examined.

Q. Where can that data be found?

A. I have a record of those data. They are all kept on file in my office.

2367 Q. Are they in any published reports, volume reports of officers here?

A. No sir.

Q. They never accompanied the reports of the message of the mayor of the city?

A. No sir, they never have been published.

CROSS-EXAMINATION,

By Mr. Todd.

Q. Doctor in these 1180 cases of typhoid that you have spoken about, were those 1180 cases of deaths?

A. No sir. Cases reported by the physicians of St. Louis, officially to the Health Department.

Q. Was that in 1900?

A. Yes sir.

Q. What was the number of cases reported in 1899?

A. Well, I haven't got that figure here right now; I couldn't tell you exactly. I had the official data, but not knowing that this would come up I haven't got the official data with me.

Q. What were the number of deaths from typhoid in 1900?

A. They were above 100, but I couldn't tell you just now; I haven't got the data here.

Q. Above 100?

2368 Q. Were there as many as 125?

A. It may be, but I am not quite sure. I cannot command the figures at this moment.

Q. It was less than 150 as you recollect it, was it?

A. I think it was, but I am not prepared to say for sure.

Q. Is there any other period in the history of St. Louis, when there were 1180 cases of typhoid previous to 1900?

A. Do you mean to say when there was less than that?

Q. More than that?

A. Yes sir.

Q. When was that, doctor?

A. To my knowledge, in 1892 or 1893, I am not certain just now.

Q. What was the number of patients sick with typhoid in 1892 or 1893?

A. It was a high figure, but I cannot recollect just now how much it was. It was several thousand.

Q. To what was that epidemic attributed?

A. That epidemic was attributed to my knowledge, to pollution of the Mississippi River from sewage in the Harlem Creek, which is a creek that discharges into the Mississippi River somewhere near the northern boundary line of the city.

Q. Was that epidemic of 1892 and 1893 preceded by cases of typhoid in the neighborhood of Harlem Creek?

2369 A. That I don't know at this moment.

Q. Do you know whether there had been typhoid among the inhabitants whose feces or urine were discharged into this creek and whether that of itself would cause typhoid to develop?

A. I am not prepared to answer that question. I cannot say. I am not positive.

Q. How many deaths occurred in 1892 and 1893 from typhoid?

A. I couldn't tell you at this moment; I haven't got the figures at hand.

Q. Was that epidemic general throughout the city?

A. That I couldn't tell.

Q. After 1892, when did you have typhoid in St. Louis?

A. Well, there has been typhoid all along every year, the statistics will show some typhoid.

Q. Attributed to what cause?

A. Well, that is a matter that I cannot answer.

Q. Did you ever give it any consideration?

A. I studied the typhoid situation in St. Louis somewhat, as far as the estimation of the cause of the epidemic of 1892 or 1893 was concerned, and I gave the question of typhoid some study after the opening of the Drainage Canal, but I did not go into any researches prior to that time.

2370 Q. Have you any idea what the number of cases reported in 1893 was?

A. Well, to my knowledge it was several thousand.

Q. In 1894, the year after the epidemic that you spoke of?

A. I couldn't tell you at this moment.

Q. Can you give me your best judgement upon it, doctor?

A. I cannot right now. A glance at the official data would enable me to answer that question at once.

Q. How is that official data prepared, doctor?

A. By the statistics obtained by the Health Department of St. Louis.

Q. Are those statistics obtained by the Health Department previous to 1900, based upon the number of cases, or upon the number of deaths?

A. I know that the statistics have been based upon both, from the number of cases and the number of deaths, and I have an official certificate from the secretary of the Board of Health certifying the official figures as taken from the official records for those periods.

Q. How long have you been connected with the Board of Health of St. Louis, doctor?

A. I haven't got it at hand just now.

Q. (Questiôn repeated)?

A. Ten years.

2371 Q. During the time that you have been connected with the Board of health of St. Louis, has there ever been a letter sent out to the physicians in the city, asking them to report typhoid cases coming under their immediate care?

A. Yes sir.

Q. When?

A. There was one issued in the fall of 1900, and another one issued in the fall of 1901.

Q. Previous to the one issued in the fall of 1900, do you know of any letter having been sent out to the physicians in St. Louis during your term in connection with the Health Department of the City of St. Louis?

A. There wasn't exactly a letter sent out, but I remember as long as I have been connected with the health department that the Health Commissioner has frequently requested physicians through the press and in official reports, to report the number of cases of typhoid more promptly.

Q. But in 1900, there was a special letter sent to all physicians, wasn't there?

A. Yes sir, there was a circular letter issued by the Health Commissioner, calling the attention of physicians to the fact that the law required them to report all cases of typhoid and all deaths from typhoid promptly.

Were there responses to that letter generally?

2372 A. Well, this way, the attention of the physicians was called to the requirement of reporting the cases. Now whether they reported them more regularly after that I couldn't tell.

Q. You got a great many replies to that letter, didn't you?

A. No, there were no replies necessary.

Q. I mean reports?

A. Well, it happened to be that these circular letters were issued just at a time that typhoid had gone up in St. Louis, the number of deaths had increased and the number of cases had increased, and naturally at that time, whether or not there had been a circular issued at that time—I presume that the number of cases reported would have increased.

Q. Well, that letter stimulated the doctors in reporting cases of typhoid, didn't it?

A. Well, it called their attention to the violation of the law in not reporting those cases.

Q. Was there any penalty attached to the violation of that law?

A. I don't know what the penalty is, but I know that physicians can be compelled to report those cases.

Q. Do you know whether there is a penalty attached to the law compelling physicians to report typhoid cases, or other epidemics?

2373 A. I cannot tell you just at this moment.

Q. Well assuming that there is a penalty attached for the violation of that law, do you know that there is any case previous to 1900 where the law has been invoked against any physician for not reporting a case of typhoid in the city of St. Louis?

A. I don't know.

Q. At the time that letter was sent out the question of opening the Drainage Canal was being agitated in the public press of St. Louis, wasn't it?

A. Yes sir.

Q. And the Health Department of the city of St. Louis?

A. Yes, there was considerable discussion. An investigation was going on at that time of the analysis of the samples, etc., and that attracted considerable attention.

Q. For seven years previous to the sending out of that letter, do you know of any publicity such as was given in 1900, as having been given to the health condition of the city of St. Louis by the public press or by the Board of Health?

A. Yes sir.

Q. For the securing of data on typhoid?

A. Yes, I remember that when the typhoid epidemic of 1892 or 1893 came, it was discussed very much. 2374

Q. That was eight years previous?

A. Yes sir.

Q. I mean seven years previous?

A. Yes, there was some discussion; there always is in connection with the discussion of the water supply and the warnings issued by the Health Department against the use of the city water, and the necessity of boiling it, etc.

Q. Your observation has been that the people pay little attention to boiling the water in the city of St. Louis, hasn't it?

A. Well, I think they pay a great deal more attention to it since 1900, than they did prior to that.

Q. I mean the people, the plain people, as Mr. Bryan speaks of them?

A. Well, I think that the entire inhabitants of St. Louis have been so fully warned against the character of the water that they today largely are only drinking boiled water or well filtered water. This number is much larger than prior to the opening of the drainage canal.

Q. Now your physicians pay more attention to the enforcement of that law than they did prior to 1900?

A. Well, that I couldn't tell. It is my impression though, that they pay considerable attention to the typhoid situation in St. Louis. 2375

'Q. Are you acquainted or have you the means of knowing what the mortality is in typhoid cases?

A. Well, the mortality of typhoid cases is recorded in the official records of the Health Department.

Q. I mean what is the general percentage, not to be accurate?

A. Well, the precentage is usually calculated on the ratio of the population per 100,000 inhabitants; that is the custom of every investigator.

Q. I am not saying—in any case of typhoid, what is the rate of mortality?

A. That I couldn't tell you. I haven't studied that question.

Q. Now previous to 1900, and the opening of the Drainage Canal in 1899, was there any typhoid in the city of St. Louis?

A. Yes sir.

Q. How many cases, doctor?

A. Well, I would have to consult the official data to tell you.

Q. What is your judgment upon the matter?

A. Well, I have looked over this data, and I have looked over a great many other data, but I cannot tell you the exact figures

Q. Give me approximately what your best judgment is?

2376 A. You mean of the number of cases?

Q. Yes, the year previous to the opening of the Canal?

A. Well, the number of cases showed a very low ratio between 1895, after the removal of the Intake to the Chain of Rocks, above the St. Louis sewers, and the Harlem Creek, showed a reduction of typhoid.

Q. I want the number, not the ratio?

A. I couldn't tell you the exact number now.

GENERAL CROW: What year?

MR. TODD: 1899. Were there 500 cases of typhoid in the city of St. Louis, in 1899?

A. There were more cases in 1899 than 500; that is, during the entire year. Typhoid was very low, but during one month they went up some.

Q. To what was that increase attributable?

A. That increase in typhoid was in November, 1899.

Q. The Drainage Canal had not been opened then?

A. That I couldn't tell.

Q. Didn't you give that any consideration?

A. I gave it some thought, and I have some views on the subject.

Q. Could you favor us with your views?

A. I haven't got anything. I haven't come to a definite conclusion as to the result of the investigation that I had
2377 carried on at that time, and am not prepared to make a statement.

Q. Will you be able to secure for me the statistics showing the number of typhoid cases in the city of St. Louis in the years 1897, 1898 and 1899?

A. Yes sir.

ATTORNEY GENERAL CROW: That is already in the record. You will find it in Dr. Ravold's testimony.

MR. TODD: I missed that.

Q. Assuming that the statements made by Dr. Ravold correctly state the number of typhoid cases in 1899 and 1898, in your investigations have you tried to ascertain what the causes were for that typhoid?

MR. WOERNER: That has been given too, Mr. Todd.

MR. TODD: I am asking him.

THE WITNESS: Well, I have attempted to investigate the matter, but I finally concluded that I might as well leave it to the chief of the bacteriological investigation, Dr. Ravold, who took up the matter and carried it on.

Q. Doctor, what do you know about typhoid fever?

A. Well, what my—

Q. Excuse me for asking the question, but does your professional calling include the treatment of typhoid, as a part of your profession?

A. No sir, I am a chemist and not a physician.

2378 Q. And all that you know about typhoid is what is known as book knowledge instead of actual experience, isn't it?

A. Well, information that I have carefully obtained by personal contact with people familiar with it.

Q. It is hearsay evidence, hearsay information isn't it?

A. And from the study of reports and books and statistics.

Q. Well, as I say, it is hearsay, isn't it; you have never treated typhoid, have you?

A. No, I have not. I am not a physician.

Q. Well, in drawing your conclusions as to the cause of typhoid, your experience has not been such in actual contact with typhoid fever, as to make you an expert upon the disease of typhoid, has it?

A. Not upon the medical treatment of typhoid. I cannot express an opinion on that, or pass judgment.

Q. Can you say now as an expert that the 1180 cases of typhoid in the city of St. Louis, or any portion of them, was attributed to the opening of the Sanitary Canal in 1900?

A. Do you mean in the city of Chicago?

Q. I mean in the city of St. Louis.

(Question repeated)

A. From a careful study—

Q. No, just repeat my question. It admits of Yes or No?

GENERAL CROW: Answer him and make your explanation.

2379 MR. TODD: I don't want to shut off anything.

Q. (Question repeated).

MR.TODD: My question is, can you say as an expert that is true?

A. Well, I can say this; from the study of the question in connection with this entire investigation, and from a great many scientific facts that have come to my knowledge, and from the testimony as it was presented here by Dr. Ravold, and from a comparison of the statistics of typhoid in the city of St. Louis, with the analytical results as obtained from the chemical investigation conducted since the opening of the Drainage Canal, on the waters between Chicago and St. Louis, I can say that it is my opinion that the character of the water coming down from the Drainage Canal, the Des Plaines River, the Illinois River and down the Mississippi River into the Intake Tower is such that all sewage polluted—that it is possible from what I know about the connection of typhoid epidemics, with the chemical character of water, that I am prepared to say that it is not unlikely that typhoid in St. Louis might come from the sewage polluted water which reaches the St. Louis intake from the Drainage Canal.

MR. TODD: Now I move to strike out the answer as not responsive to the question.

Q. Are you an expert on typhoid? Can you answer that "Yes" or "No?"

2380 A. If you construe it as connected with the medical features of typhoid, I would say "No."

Q. I don't want to construe it, doctor; I want you to construe it, and I will follow up your construction. Now do you consider yourself an expert on typhoid?

A. Well, I will interpret your question in the way I said just now, and say No.

Q. Do you know the symptoms of typhoid?

A. Well, I have had typhoid myself three months, some years ago and I recall the symptoms which were diagnosed as those of typhoid at that time.

Q. Were you attended by a docter?

A. Yes sir.

Q. Did you diagnosticate your own case, or did you get the doctor to do it for you?

GENERAL CROW: I object on the ground that the witness has already said he wasan't qualified to testify in that way.

THE WITNESS: I was then eighteen years old and I took a great interest in the matter.

MR. TODD: Then going back to your other answer that you are not an expert on typhoid; can you as an expert in chemistry attribute any part of the 1180 cases in 1900, to the opening of the Drainage Canal?

A. Indirectly, yes; in connection with my statements.

2381 Q. Do you consider it a cause or an incident?

A. You mean what?

Q. The 1180 cases of typhoid in 1900, and the opening ot the Drainage Canal?

A. I consider it in a measure as very striking that with the increase of the pollution of our water supply, and the increased pollution of the Des Plaines River from the Drainage

Canal and the Illinois River and the Mississippi down to the intake in the year 1900, I consider it very striking that there was corresponding with that increase in pollution in the month of March, 1900, an increase in typhoid of 1300 per cent over the average of the five preceding years for the number of cases in St. Louis. That typhoid epidemic followed a pollution of the water supply, as traced up the Mississippi; then up the Illinois, up the Des Plaines River to the Drainage Canal, was followed by the pollution so high as was never before experienced in St. Louis; that is, no previous water analyses ever showed such high pollution, such sewage polluted water as went into the intake tower and went through the reservoir, and came from the taps of the hydrants in February, 1900.

Q. A person not a chemist nor an expert on typhoid could draw the same conclusions, couldn't he, doctor?

A. If he would give the matter as careful study as I have tried to do I think he could. 2382

Q. In making your study, didn't you consider it essential to find out the cause of the typhoid existing in St. Louis during the four or five years previous to the opening of the drainage channel?

A. Well, in a measure I have done that by ascertaining whether or not the typhoid cases, the high typhoid cases, and the increase in 1900, was due to the drinking of well and cistern water in St. Louis, or was due principally to water coming from the hydrants, as it was established by this special investigation I referred to today.

Q. During the five years previous to 1900, was the water supply of St. Louis, as found in these hydrants, good, potable water?

A. No sir.

Q. Did it require boiling?

A. Yes sir.

Q. Did it require filtration?

A. It should have been filtered, yes.

Q. Now do you compare potable water or drinking water as being bad or worse?

A. I do compare the analytical results in 1899, prior to the opening of the canal. I compare those results with those

of 1900, 1901 and 1902, after the opening of the canal, and
2383 the water has become worse in its chemical character since the opening of the Drainage Canal.

Q. But before that it wasn't drinkable, was it?

A. Frequent warnings were issued by the Health Department and myself to boil the water or filter it well before drinking it.

Q. Why were those instructions given, doctor?

A. Because the water was not found to be potable.

Q. Would the water as it existed today, if filtered or boiled be as good as the water that existed prior to 1900, if boiled or filtered?

A. Presumably it would.

Q. For how long a period of time has the health department of St. Louis advised the citizens not to drink the water of St. Louis?

A. Oh, that has been done since 1893, since I assumed charge of the office of City Chemist and analyzed the water.

Q. What was the character of the pollution of the water in St. Louis prior to the opening of the Sanitary District?

A. The water as proved to be prior to the opening of the Drainage Canal, was polluted.

Q. With what?

A. The analytical results showed pollution in a measure from sewage and in a measure of vegetable origin.

2384 Where did the sewage come from that got into the water of St. Louis?

A. In my opinion, as a result of my investigation in 1899, I found that the Missouri River and the Mississippi River above the mouth of the Illinois, were of much better sanitary quality than the Illinois River at the mouth of the Illinois, and I found at that time that the Illinois River polluted the Mississippi River after meeting the Mississippi River and that this pollution extended along the line or along the route of the Mississippi River as it came down and passed the intake, or at times when the Missouri River was low, it would go into the intake.

Q. At that time was the Missouri River water potable water?

A. Yes sir.

Q. And is Missouri River water now potable water?

A. Yes sir.

GENERAL CROW: Are you speaking chemically and bacteriologically, or chemically alone?

MR. TODD: I would like to ask him a question on that line, Mr. Crow, if you don't object.

Q. Doctor, you have given no attention to the study of bacteriology?

A. I have, some, yes.

2385 Q. You don't class as an expert on bacteriology, do you?

A. Well, bacteriology as connected with the chemistry of water, I have given considerable study.

Q. Then in your testimony, you testified in this case as a bacteriological chemical expert?

A. I testified as a chemical expert who is supposed to make himself familiar with all the bacteriological features connected with the chemistry of water.

Q. Now, with that understanding, did you regard the waters of the Missouri River as being potable waters chemically and bacteriologically prior to the opening of the Drainage Canal?

A. Well, chemically I am prepared to answer that question "Yes;" but bacteriologically I am not prepared to answer the question.

Q. Why, doctor?

A. Because I have not given the strictly bacteriological feature of that water any special study; that is, I studied the bacteriology of the water, as far as it is connected with certain chemical changes going on in the water, for instance the action of the an-aerobic and the aerobic bacteria. It is my duty to inform myself on that point, but I have not made investigations strictly on the bacteriology of water, such as determining and making the counts and the determinations of the presence of pathogenic bacteria, etc.

2386 Q Have you had anyone doing that for you, under your direction, in connection with the city health department?

A. No sir.

Q. Was that done prior to the opening of the Drainage Canal?

A. Yes sir.

Q. And by the health department?

A. Yes sir, and under the direction and supervision of Dr. Amand Ravold.

Q. And he has testified to the condition of the water here, hasn't he?

A. Yes sir.

Q. I was not present myself.

A. Yes sir.

Q. Was the water of the Mississippi River prior to the opening of the drainage canal potable chemically?

A. Do you mean the Mississippi River after—

Q. Above the intake?

A. That is after it met the Illinois River?

Q. Yes. I understand the Illinois River meets the Mississippi River about 20 miles above the intake; is that right?

A. How is that?

Q. The Illinois River empties into the Mississippi about 20 miles above the intake; is that correct?

A. No, it is 34 miles.

2387 I am speaking now above the intake.

MR. WOERNER: And below the mouth.

MR. TODD: I mean within five miles above the intake of the St. Louis water supply.

A. That is, above the mouth of the Missouri?

Q. Yes?

A. That water was not potable.

Q. Now what proportion of the year did the water of the Mississippi within five miles above the intake of the city of St. Louis, enter the intake?

A. At what time?

Q. During the year, what proportion of the year did the citizens of St. Louis drink Mississippi water prior to 1900?

A. Well, that cannot be estimated according to a particular season or time of the year. The amounts of Missouri and Mississippi River water coming down the channel and prevailing in the channel and then going into the Intake all these years varies considerably, varies daily, and it is very difficult to generalize there, but approximately, taking the whole year together

I am prepared to say that about seventy-five per cent. that is the daily quantity of water going into the Intake there would be Missouri River water, and about 25 per cent. would be Mississippi River water.

Q. That is, during the year?

2388 A. That is during the entire year, but it may vary so much, that on one day it might be a very high percentage of one river and the next day turn right around and show probably a difference of fifty per cent. just according to the stage of the river and the volume of water coming down from the big watersheds the three big watersheds, the Illinois, Missouri and Mississippi.

Q. About seventy-five per cent. of the time?

A. Yes, if you take the whole time together.

Q. Would be Mississippi River water?

A. No, woud be Missouri.

Q. Seventy-five per cent. Missouri River water?

A. Yes, sir.

Q. And twenty-five per cent. Mississippi water?

A. Yes, sir.

Q. Does that continue for any period of time?

A. No, as I said, it varies from day to day; it is simply a yearly approximation.

Q. You would have a period of nine months where you drank nothing but Missouri water?

A. I said this wouldn't apply to nine consecutive months which would be three-quarters of the year. I said that daily for the whole year it would amount to—

2389 MR. WOERNER: Say no, doctor, and be done with it.

Q. MR. TODD: Was 25 per cent. of the Mississippi water sufficient to contaminate and pollute 75 per cent of the Missouri water that entered the intake?

A. You couldn't draw that comparison, that contamination, because it is an approximation.

Q. Well, would the amount of water entering the Intake, the Mississippi water, be sufficient to keep the water supply of St. Louis in a polluted condition?

A. The fact that whole days during this period when the percentage of Missouri River water going into the Intake is 100 per cent., and that soon after I will say, within a week afterwards or two weeks afterwards there might be 100 per cent. of Mississippi water going into the Intake, that no such comparison could be drawn; you couldn't get any results from it because it varies too frequently in the percentage.

Q. The results at the City Chemist's office would answer my question, and that is is the water polluted the year around?

A. Yes, sir.

Q. By the Mississippi River water?

A. It is considerably polluted always when the percentage of Mississippi River water, as estimated from the residue on
evaporation of those two rivers, the Missouri and the Mis-
2390 sissippi, and then at the Intake, whenever that percent-
age is high, of course the pollution of the water is increased, and whenever the Missouri River water prevails at the Intake Tower, in other words, when nothing but Missouri River water goes in, the water at times, may be considered potable. That is, it isn't all the time so bad that I cannot call it potable, but it is not potable at such times when water like that running along the Illinois shore, down the Mississippi, when that gets into the Intake.

Q. Those days when the water supply of St. Louis is potable are exceptions instead of the rule, aren't they?

A. No, sir; they are not exceptions to the rule because—

Q. I am talking now of previous to 1900. Was the water supply of St. Louis potable all the time or was it polluted?

A. As I have stated in my testimony in direct examination, prior to January, 1900, the water supply of St. Louis as coming from the water going into the Intake was potable at times. I said in my conclusions there were great variations, and at some times the water would be a good drinkable water, the water would be potable, and at other times it would be very bad, polluted, as I said.

Q. What I want to get at is, what is the proportion of time that it was polluted to the time it was potable?

A. That I could not estimate for that period because I
2391 did not make daily examinations at that time. I did not
take daily samples during 1899, prior to the opening of the canal.

Q. Now, above Grafton, was the water of the Mississippi River prior to 1900, potable?

A. The water of the Mississippi above Grafton, yes, it was.

Q. Now, what is the volume of water that empties into the Mississippi River from the Missouri in its normal condition?

A. That I couldn't tell you off-hand. I would have to refer to the figures and consult the data.

Q. How far south of the Missouri River does the water of the Missouri hug the shore of Missouri, and retain its identity?

A. Well, I have never analyzed any water south of the Chain of Rocks, so I cannot tell from analyses.

Q. Have you ever made observations of it from the Eads Bridge?

A. I have made observations from the Merchant's Bridge, and in looking up the river, just for that particular purpose, and I cannot deny that it is noticeable that the water running along the Missouri shore was much heavier in sediment, it had more clay and silt in it than the water running along the Illinois shore.

Q. Did you ever observe it at the Eads Bridge?

A. I cannot recollect it, no, sir.

2392 Q. Have you ever observed it on the banks of the river in front of the city?

A. No, sir, but I have noticed it from the harbor boat and from boats going up the river.

Q. Is it discernible?

A. There is a channel, you see, where the mixture takes place, and that is an intermediate stage between the two. There is not a strict line of demarkation there.

Q. Is the current of the Mississippi River found in the current of the Missouri?

A. That depends upon the stages of the river.

Q. Well, in normal stages?

A. At times it may, and at times it may not; the current varies very much, because the Mississippi is fed there by three watersheds, the Missouri, the upper Mississippi and the Illinois, and the constantly varying stages, and the constantly varying quantity of rain-fall in these river flows, which changes the velocity of the current very much in the Mississippi.

Q. Well, does the normal condition in the Missouri river prevail the greater part of the year?

A. No, I don't think so because the flood volume coming down the Missouri River in the spring time is very large and produces variations in the stages of the river.

2393 Q. Well, is the Missouri higher a greater part of the year?

A. It is usually higher during the spring and summer months.

Q. How about the Mississippi, is its condition normal during a greater part of the year?

A. Well, the Mississippi River stages are also affected by the quantity of rain fall in these two big watersheds, and the varying volume of water coming down these watersheds.

Q. And the Illinois is it a swift running river or slow?

A. It is prevailingly a slow river, sluggish current.

Q. How does it compare with the Missouri and the Mississippi?

A. Its current is supposed to be slower, and the results of examinations as published demonstrate that.

Q. How does the volume of the water of the Illinois compare with the volume of the Mississippi at the place where the Illinois empties into the Mississippi?

A. Well, that varies greatly. The volume of water coming down the Illinois River sometimes may amount to 1200 cubic feet, and then it may amount—

GENERAL CROW: Per second or per minute?

A. Per second.

MR. TODD: 1200 cubic feet per second?

A. Yes, and then it may be 112,000 cubic feet per second;

2394 then the volume of the Mississippi River above Grafton can also vary enormously.

Q. Does the volume of the Mississippi ever go down to 1200 cubic feet per second?

A. I don't think so from what I have studied about it.

Q. Does the volume of the Mississippi ever go down to as much as 300,000 cubic feet per second at Grafton?

A. I couldn't tell you at this moment. I would have to consult data.

Q. When the Mississippi River coming down below Grafton, and the waters of the Illinois coming in contact with the waters of the Mississippi, the Mississippi current is always swifter than that of the Illinois, isn't it?

A. Yes, as a rule.

Q. The Illinois River comes in on the Illinois shore, and the swifter current of the Mississippi bears the water of the Illinois onto the Illinois shore, doesn't it as it comes down?

A. It does that somewhat, but there are a great many curves there bewteen Grafton and the mouth of the Missouri produced by dikes extending from the Missouri shore far into the river, cross-sectioned and extending from the Illinois shore far into the river, so that there is a narrow channel there, running right around those curves, and this channel, of course, has
a different velocity than the water that is kept at the
2395 dikes, and the water that almost stagnates in times of
low water stages in the summer, in the corners of those
dikes, and that produces different conditions. The channel there, will be quite a mixture. Now, of course, if the Mississippi River is very high above the mouth of the Illinois—it could be very high in a day and the Illinois very low, why then the water prevailing in the channel between Grafton and the mouth of the Missouri might be principally Mississippi River water.

Q. But the point I make is, the Illinois River water retains its identity how far from its mouth coming south along the Illinois shore?

A. Yes, the Illinois River water as it runs along the Illinois shore, is stopped by those dikes, and it is kept in the corners of the dikes, and only a part of that water is gradually, when the upper rivers rise, swept out, and gets into that narrow channel, so that the identity of the Illinois River as such, would, in my opinion, be lost before it reaches the Intake of St. Louis. From the mixture we can trace many curves.

Q. Have you made a cross-section of the Mississippi River above Grafton?

A. No, sir.

Q. Have you made a cross-section of the Mississippi River below Grafton?

2396 A. Yes, sir.

Q. In how many places?

A. Alton and Hartford.

Q. Only two?

A. I have taken cross-sections there of twelve samples across the Mississippi River one mile above Alton and Hartford.

Q. You don't get my point. How many samples did you take on a line intersecting the Mississippi River below Grafton, which is called a cross-section?

A. Twelve.

Q. Twelve right across?

A. Right across, yes, sir.

Q. At one time?

A. Yes, sir.

WILLIAM C. TEICHMANN.

Adjourned until 10:00 a. m., Tuesday, March 31, 1903.

2397 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Tuesday, March 31st, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN resumed the stand for further cross-examination, by Mr. Todd, and testified as follows:

Dr. Teichmann, you stated, I believe, at the conclusion of the testimony yesterday, that you took samples below Grafton, Illinois, on the Mississippi River?

A. Yes, sir.

Q. That is what is known as a cross-section, is it not?

A. Yes, sir.

Q. And that you took twelve samples between two points at one time, across the Mississippi River below Grafton?

A. Well, I took cross-sections at three points.

Q. I am taking just one point at a time.

A. Yes.

Q. The first point?

A. The first point is Alton.

2398 Q. Was Alton?

A. Yes, sir.

Q. That is from Alton to West Alton?

A. Yes, right across the river there.

Q. Now, you took twelve samples at that point?

A. Yes.

Q. How many days did you take twelve samples?

A. Cross-sections were taken on—now let me see—I am not quite sure whether it is two or three times that I took those cross-sections.

Q. Were they all in one day or at different days?

A. Different days, yes.

Q. How far apart, between the taking of those samples at that point?

A. Well, they were equally divided, so that they would practically cover the entire width of the river at those points.

Q. What was the duration of time between the taking of the samples between Alton and West Alton, on the line of the cross-section?

A. Well, they were taken by the two men in one boat.

Q. No, you don't get the idea, doctor. You took twelve samples to-day?

A. Yes, sir.

2399 Q. Now, did you take twelve samples tomorrow, and twelve samples the day before? You said you took them on three occasions.

A. No, there was a longer interval between those three days. It is some time since I looked at those charts—

Q. Can you approximate it?

A. I couldn't tell you off-hand. I have the data in the other room. I can get them in a few minutes.

Q. I would like to have you get that data, doctor.

A. Yes, I will get them.

(Upon returning to Court room, witness stated that the charts had been returned to his office by mistake, but that he had telephoned for them.)

THE WITNESS: I was mistaken in regard to those cross-sections at Alton and Hartford. For one month these cross-sections were taken daily for five points at Hartford and Alton, but the cross-sections taken at the Chain of Rocks—those were taken at a dozen points across the river. I confounded those. I would rather wait until I get those charts.

MR. TODD: Well, I will resume the cross-examinaton on that point when you get the charts. I will take up another matter.

Q. When was it that you examined—that you made the examination of the Desplaines River above Lockport, before the waters of the Drainage Canal emptied into it?

2400 A. There were no examinations made in our laboratory of any waters from the Desplaines River prior to the opening of the Drainage Canal. They began on March 3rd, 1900.

Q. At what point in the Desplaines River did you take samples?

A. Do you mean in the Desplaines River?

Q. Above Lockport?

A. Above Lockport?

Q. Yes?

A. Well, that was in the Desplaines River some distance up the Desplaines River above the junction of the Canal and the Desplaines River—the Drainage Canal and the Desplaines River.

Q. That was before the waters of the Sanitary Canal emptied into the Desplaines River?

A. Yes, the Desplaines River water was analyzed—

Q. That is all; I just want that question.

A. (continuing)—in 1901.

Q. How many samples were taken at that point?

A. Well, there were—let's see—from the Desplaines River above the Bear Trap Dam daily samples were taken in October and November, 1901.

Q. You analyzed those samples, did you, doctor?

A. Well, I—

2401 Q. Or caused them to be analyzed under your direction?

A. Yes, I superintended the analyses.

Q. From the analyses what conclusion did you draw as to the potability of the waters of the Desplaines?

A. I stated in my testimony that I considered that water potable water.

Q. And was that opinion arrived at from the analyses of the water in that river at that point?

A. Yes, sir, for those two months.

Q. What is the volume of the Desplaines River?

A. You mean—

Q. In water?

A. Just before it reaches the Drainage Canal?

Q. At the point where you took your samples?

A. Well, the volume there varies very much according to the statement of the Chief Engineer, Mr. Randolph, of the Drainage Canal.

Q. About the time that these samples were taken, doctor, is what I am interested in?

A. Well, that I couldn't tell you at this moment; I would have to look up the data.

Q. Was it high water or low water in the river at that time, do you know?

A. I cannot recollect at this moment; I knew it at the time.

2402 Q. And you say that that water was potable?

A. Yes, sir.

Q. You mean by that, good drinking water?

A. Yes, sir.

Q. Do you know what towns empty their sewage into the Desplaines River?

A. I do not know at this moment.

Q. Do you know that the sewage of Riverside, of about 5000 inhabitants, empty their sewage into the Desplaines River above that point, and the village of La Grange?

A. I know that some towns drain their sewers into those rivers—into that river.

Q. Do you know that the waters of the Desplaines River have been condemned by the Board of Health of the City of Chicago as being contaminated, and that ice men are prohibited from selling the ice from that river?

A. No, sir; I don't know that fact.

Q. If those facts should appear to you, that the village of Riverside, located within ten miles, and La Grange, and Maywood, and other suburban towns were draining their sewage into that stream, would you still call that a potable water?

MR. JEFFRIES: We object to the question because the question does not state the population of the towns mentioned, as draining their sewage into the Desplaines River.

2403 Q. Just answer the question.

A. I drew my conclusions from the analytical data that we received from the analyses of those samples from the Desplaines River in October and November, 1901, and I feel justified in stating that from those analytical results I must consider the water of the Desplaines River for those two months, at least, of our examination, as a potable water, just at the point before the Drainage Canal discharges its waters into the Desplaines.

MR. JEFFRIES: You haven't answered the question, doctor.

THE WITNESS: Would you please repeat the question and I will answer the question.

MR. TODD: The reporter will read you my question.

(Question read.)

A. I could only base an opinion on the analyses of the samples taken from that river.

Q. Then if the sewage of these different places that I have indicated, does empty into the Desplaines River, and did empty at the time that you made your examination, purification of that sewage had been completed at the point that you made the examination. Is that correct?

A. Yes, sir; if the facts are such; provided, however, that the volume of water was sufficient, and the Desplaines River at times can discharge as much as 600,000 cubic feet of water per minute. 2404

Q. Well, assuming the volume of water that was there at the time that you took the samples out of the Desplaines River, can be ascertained, and I assume that it can—you could give me the data on that couldn't you?

A. Yes, sir.

Q. And assuming also that the sewage from these points above there was emptied into that River, before that sewage got to the point that you took your samples, it had been purified, and the water had been rendered potable according to your analyses, is that correct?

A. Yes, my analyses established the fact that during those two months the water taken from the Desplaines River was potable before it reached the Drainage Canal.

Q. The condition of purification in the Desplaines is not different from the condition obtaining in the Illinois, is it?

A. Well, it depends very much upon local conditions. They may change the conclusions very much. No conclusions can be based absolutely on certain facts without taking into consideration the general conditions; the volume of water and the character of the sewage, and the population of the towns draining their sewage into the river.

Q. Well, I mean the principles of purification will apply to the Desplaines River the same as to any other river, would they not?

2405 A. Well, if the conditions were alike, of course.

Q. Well, that is the principles, depending upon conditions?

A. Yes, but the general—a general assumption nowadays is that local conditions have to be taken into consideration in determining a question of purification.

Q. What is your opinion, doctor, as to the effect of running water upon sewage? Does it purify itself or not?

A. That depends very much upon the conditions prevailing in those running waters, and the volume of water, the character of the sewage; the question would come into consideration whether or not pathogenic germs are contained in that sewage, and various other questions that all would have to be considered before a general opinion coud be formed in each case.

Q. Have you given the subject sufficient consideration to be able to enunciate a principle applicable to the purification of streams sewage contaminated?

A. No, sir; not absolutely.

Q. Do you know whether sewage contaminated streams will purify themselves within a given distance?

A. That is a question which again cannot be defined per se. It would require a careful consideration of local conditions; the volume of water, the character of the water into which the sewage is discharged, the character of the sewage, as I said before—whether pathogenic germs are contained in the sewage, etc. 2406

Q. Suppose we eliminate, doctor, the bacteriological from the chemical and address yourself to the chemical; what do you mean by the character of the water?

A. The character of the water is determined by chemical analyses looking for characteristic ingredients of pollution, whether of animal or vegetable origin..

Q. What do you mean by the volume of the water?

A. The volume of the water is important in so far that the current will be greatly accelerated in the running river by a larger volume of water, and the sewage will be carried down the river much faster and go a longer distance.

Q. What is your opinion as to whether the sewage of a population of 500,000 inhabitants, being emptied into a river the size of the Mississippi at St. Paul and Minneapolis—at what distance would the waters of the Mississippi purify themselves, and become potable, after receiving the sewage of St. Paul and Minneapolis?

A. I have not made any analyses of the waters between St. Paul and the mouth of the Illinois River, excepting a few miles in the Mississippi above the mouth of the Illinois, so that I am not prepared to make a statement answering that question.

2407 Q. Have you any opinion as to whether the Mississippi River, after receiving the sewage of St. Paul and Minneapolis, subsequently purifies itself?

A. No, sir.

Q. Do you know whether the Mississippi River purifies itself from the sewage pollution of St. Paul and Minneapolis?

A. Well, that is a matter that I have not investigated, except that I know that the Mississippi River water at the mouth of the Illinois, is a comparatively much purer water than the water found in the Illinois River at the mouth of the Illinois.

Q. Read my question, please?

(Question read.)

MR. TODD: I move to strike out the previous answer as not responsive, and ask to have the question read again and an answer that is responsive, given.

THE WITNESS: Will you please read the question again?

Q. (Question read.)

MR. TODD: That can be answered yes or no, doctor. The question is, do you know?

MR. JEFFRIES: We object to the question for the reason that it neither tends to prove or disprove any material issue

involved in this controversy and for the further reason that the fact as to whether or not the waters of the Mississippi River would purify themselves from their polluted state caused
2408 by the sewage discharges at St. Paul, by the time the City of St. Louis is reached, has no bearing upon this controversy, and wouldn't justify or excuse the defendant, Sanitary District of Chicago, in discharging its sewage into the Desplaines River, thereby polluting the natural streams foreign to its own watershed.

Q. (Question repeated.)

A. I cannot answer that question.

Q. MR. TODD: Do you know?

MR. JEFFRIES: Give your opinion, doctor, as an expert?

A. Well, I don't know.

Q. MR. TODD: That is what I mean.

A. Yes.

Q. What effect upon the waters of the Mississippi would the sewage from McGregor, Prairie du Chien, and Dubuque have in addition to the sewage from St. Paul and Minneapolis?

MR. JEFFRIES: We object to the question for the same reason embodied in the objection to the question that refers to the sewage from St. Paul.

Q. MR. TODD: Do you know?

A. I do not know, because I am not familiar with the conditions prevailing in any of those Mississippi River cities.

Q. Is it an established principle that sewage contaminated water receiving a discharge of additional sewage, retards
2409 the purification of the last discharge of sewage?

A. That again depends upon the relative proportion—

Q. Is it a principle?

A. Well, it cannot be answered, I say it depends upon the comparative proportions of the amount of sewage and the character of the waters.

Q. As a general principle, is that true?

A. It may be true in one case, and may not be true in another case. It depends upon local conditions.

MR. JEFFRIES: He is asking you about a general principle, doctor.

A. Well, I cannot accept a general principle, when there are instances pro and con.

MR. JEFFRIES: Well, can you state the principle and then give the exceptions afterwards?

A. I don't know which would be the exception in that case.

Q. MR. TODD: Then you have no knowledge upon which you can establish a general principle applicable to that condition, have you?

A. I base my opinion—

Q. No. Answer my question?

A. (continuing)—on the facts as I find them in the particular case.

2410 MR. TODD: I move to strike out the answer and ask to have the last question read.

Q. (Question read.)

A. To what condition?

Q. A condition that where a river is sewage polluted by a city above and running down past another city has had additional sewage emptied into it, would the condition of the water when it arrives at the latter place, retard the purification of the sewage from the latter city?

A. That question can only be answered by taking into consideration the local conditions at the points involved.

Q. Doctor, my question is, have you any knowledge?

A. Certainly I have some knowledge on that point.

Q. Based upon a general principle that sewage contaminated water from cities above, receiving an additional discharge of sewage from cities below, that the water of the river so contaminated at the time of the additional discharge, will retard the purification of the stream?

A. Yes, sir.

Q. You say you have knowledge?

A. Yes, sir.

Q. What is the general principle; does it or does it not retard the purification?

2411 A. No general principle could be formed there.

Q. Then there is no general principle applicable to a condition of that character?

A. No; theoretically not. It all depends upon the practical investigations—

Q. That is all I want, doctor. You have answered my question.

A. Yes.

Q. Now, assume that the Mississippi River at St. Paul and Minneapolis receives the sewage discharge from the population of those two cities, and that it constantly receives the discharge of sewage from the cities lying along its banks below St. Paul and Minneapolis, the cities of Dubuque, Clinton and Quincy—do you know whether the river will purify itself from the sewage discharge of these cities below St. Paul and Minneapolis, on account of having been impregnated with the sewage of St. Paul and Minneapolis?

A. I don't know, because I have not made any investigations on that line at those points.

Q. Assume that the sewage of St. Paul and Minneapolis did not empty into the Mississippi River, but that the sewage of the cities below Minneapolis and St. Paul emptied into the Mississippi River, would the fact that that sewage entered pure water, purify itself quicker than it would if it entered
2412 sewage contaminated water from St. Paul and Minneapolis?

A. I could only answer that question after an investigation of the conditions prevailing in the rivers at those cities.

Q. You have no knewledge then, as to the general effect of conditions such as I have assumed, have you?

A. Not as far as the sewage from those cities is concerned, that you have mentioned just now.

Q. Then with the addition of the sewage of Burlington, Keokuk, Rock Island, Moline and Davenport entering the Mississippi River and all of the cities and villages lying tributary to the Mississippi emptying their sewage into the Mississippi, have you any knowledge as to whether the river purifies itself or not of that sewage?

A. I have no knowledge, because I have not investigated that problem for those cities.

Q. Is there any principle established by science that holds the doctrine that the river does not purify itself of that sewage?

A. You mean to say that the sewage from those cities—

Q. Yes. Is there any principle established by chemical science that holds that the river would not purify itself of that sewage that it has received?

A. I don't know of any as applied to those conditions prevailing in the Msisissippi River above the mouth of the Illinois.

2413 Q. What is the condition of the waters of the Mississippi River above Grafton, as to whether it is potable or not?

A. While I consider the Mississippi River a few miles, from three to five miles above the mouth of the Illinois River as polluted I do not consider it as badly a polluted river as compared with the Illinois River.

MR. TODD: I move to strike out the answer as not responsive to my question and ask to have the question re-read.

Q. (Question repeated.)

A. You ask whether it is potable or not?

Q. Yes?

A. At certain times that water is potable.

Q. What's that?

A. At certain times during the year the water of the Mississippi River above the mouth of the Illinois, from three to five miles above the mouth of the Illinois, that water is potable, at other times it is not potable; it varies according to the amount of impurities.

Q. What were the periods of variation during the year?

A. During the summer months the analyses of samples shows for the Mississippi River a few miles above Grafton, shows low impurities.

Q. (Question repeated.)

I mean that the water was potable or was not potable?

2414 A. During the summer months the water found at the points from three to five miles in the Mississippi above the mouth of the Illinois River was potable.

Q. What months were those? Give the months?

A. That is principally during the summer months.

Q. Name the months, doctor?

A. Well, I would have to consult the data to be accurate, to say exactly which months, but during the warmer period of the year the water from that river is always better than it is during the winter months.

Q. How many months in this climate do you consider summer months?

A. June, July, August, and in St. Louis, very often we have summer weather prevailing through the month of September.

Q. Then for those four months you consider the water as potable?

A. I do.

Q. Above Grafton?

A. Yes, sir.

Q. How do you explain the potability of the waters during those four months when you take into consideration that the sewage of all the cities along the Mississippi River from St. Paul to Grafton, is emptied into that stream at different points, according to their location?

2415 A. During the warmer months of the year the purification processes in the rivers are greatly accelerated. They are performed more rapidly than during the winter months.

Q. The rivers are at the lowest stages during those months, aren't they?

A. Not always. After the spring months, after the usual rise in the rivers, what you call the spring rise of the rivers is very high water, consequently larger volumes of water coming down the river.

Q. What are those rises attributed to, doctor?

A. Well, to the spring freshets, and the melting of the snow in the mountains, and sometimes the rain-falls are very heavy in the spring.

Q. Do the rises continue during the summer months?

A. No, but we have what you call a June rise, for instance.

Q. Well, when you have the June rise, do you have potable water in the river above Grafton?

A. The analyses show a gradual reduction of the impurities.

Q. I didn't ask for analyses. I asked you if you had potable water—we are laymen and the word "potable" means a lot to us.

A. The potability increases and decreases gradually; it don't come all of a sudden.

Q. Well, when the water rises at that stage which you
2416 denominate as potable, is it at the rise of the river caused
from the spring, or is it at that stage of its decline?

A. The potability increases in the spring slightly with the warmer weather.

Q. Is that accompanied by the increase in the volume of the water, or by a decrease in the volume of the water of the Mississippi?

A. Well, during the summer months—not always; it depends upon the weather conditions. Sometimes there are heavy rain-falls in June and we have had heavy rain-falls in July. It is difficult to draw a conclusion.

Q. Does a heavy rainfall in July affect the potability of the water?

A. Well, the potability of the water, as I said, depends very largely upon the weather conditions, the temperatures. In warmer weather the oxidation is more rapid.

Q. Assuming that the temperature is normal for the summer, would the fall of rain affect the potability of the water of the Mississippi River at Grafton?

A. The rain-falls act very peculiarly upon the chemical conditions of the rivers. While the chlorines will be diluted by a larger volume of water, the ammonias are frequently shown to rise.

Q. Stick to the word potability, doctor. We understand 2417 that. If we have learned what potable waters mean, from your testimony, based upon these different chemical ingredients, stick to the word "potable."

Now, does the rain-fall in July affect the potability of the water in the Mississippi river above Graften?

A. That depends upon the conditions, whether the water is cold or warm.

Q. Assume that the temperature is warm?

A. Certainly, warm temperature will assist materially in purifying.

Q. And the water remains potable?

A. Well, it assists in making it potable, in warmer weather.

Q. Is it not a fact that if the rains covering the watershed of the Mississippi River above Grafton, that it washes down into the river the drainage of the farms and the stables and flushes out the creeks, and the sewers of the cities, and throws more impurities into the river, thereby creating a greater contamination; isn't that true?

A. Such a condition may prevail in the Mississippi. It depends entirely on the circumstances at those places where these impurities get into the river, and it depends upon whether it is pollution of vegetable or animal origin, which materially affects the question of potability of water.

2418 Q. Well, wouldn't that be accelerated, the pollution of animal origin, to have a heavy rain-fall along the tributaries of the upper Mississippi?

A. If there are accessions of organic matter of animal origin, they will certainly be swept down much faster by a rapid current caused by an increased volume of water.

Q. And wouldn't that disturb the potability of the water at Grafton, even in warm temperature?

A. That would again depend upon the character of the pollution and depend upon the kind of water that such organic matter is discharged into. Again the local conditions will have to be considered.

Q. Then, if the waters of the Mississippi River for four months during the summer are potable, isn't the conclusion irresistible that a running stream the size of the Mississippi River will purify itself from all impurities, and from all sewage that has been discharged into it above Grafton?

A. Such a conclusion would not be justifiable unless based on a careful study of all local conditions; the character of the pollution of that water; the amount of sewage coming or being discharged from all of these cities into the river; what the distances are, etc., of the towns to the point at the mouth, the volume of water, the weather conditions—everything would go into consideration. No hard and fast rule could be evolved from such a theoretical question.

2419 Q. Doctor, if the waters at Grafton were chemically decided to be potable, is not the conclusion irresistible that the sewage, however magnified or increased in the upper Mississippi has been purified by the time it got to Grafton?

A. It would demonstrate that the pollution of the Mississippi River above Grafton is of such a character that it doesn't affect the potability of the water of the Mississippi at the mouth of the Illinois.

Q. And how is that question of potability arrived at aside from the theory that running water purifies itself in a certain distance if the analyses of the water demonstrate beyond question that the waters at Grafton are potable?

A. It is possible that such purification may take place, but it is necessary for various conditions all to co-operate to being favorable to such a result being obtained.

Q. Do not all conditions operate favorably, and do not the waters sewage contaminated become purified when such results at Grafton obtain?

A. I wouldn't say so, because I am not familiar with the conditions which I consider necessary for consideration to determine that question, the conditions in the Mississippi River above Grafton existing at the mouth.

2420 Q. Well, doctor, if those conditions do not obtain, what effect do those conditions have in deciding whether a stream polluted by sewage purifies itself, when your chemical analyses at Grafton demonstrate the potability of the water?

MR. JEFFRIES: I object to the question, because it is an argument to the witness.

A. All the conditions that I have mentioned as being required in the consideration of the question as presented by you, all those conditions will have to be considered before anybody could answer that question in the direct manner that you desire.

Q. Doctor, you understand that the sewage of St. Paul and Minneapolis empties into the Mississippi River, don't you?

A. I don't know whether it does; I presume though from your statement that it does.

Q. You understand that the sewage of McGregor, Prairie du Chein, Dubuque, Clinton, Keokuk, Moline, Rock Island and Davenport, empty into the Mississippi River, don't you?

A. Well, I presume so from your statement; I don't know personally.

Q. Assuming that they do, and also assuming that the chemical analyses are correct, that the waters at Grafton are purified and are potable, what weight have those conditions that you speak of, upon the results which you obtained by your analyses at Grafton?

2421 MR. JEFFRIES: I object to the latter part of that question for the reason that it does not contain the number of population that those cities have.

Q. (Question repeated)?

A. I cannot answer that question, because I am not familiar with the conditions in the Mississippi River valley above a point five miles above the mouth of the Illinois.

Q. Have you a theory in regard to those conditions you speak of?

A. I have no theory that I would apply to every case.

Q. Well, a theory of the conditions that exist along the Mississippi above Grafton?

A. No, I have no theory because I have not investigated the conditions prevailing in that river except by analyses five miles above the mouth of the Illinois.

Q. Well, when you made analyses above Grafton, you were confronted by the condition, not a theory, aren't you?

A. Yes sir.

Q. And the condition—with due apologies to Grover—that you find there, is that the water is potable, is it not?

A. Yes, at certain times of the year the water is potable.

Q. I mean during four months?

A. Yes sir.

2422 Q. Now, assuming that the sewage from the cities that I have mentioned and their population as given in the census are correct, and empties into the Mississippi, aren't you drawn from the condition you find, to the irresistible conclusion that the Mississippi River purifies itself of all that sewage before it gets to Grafton?

A. I don't know the conditions prevailing in that valley and I don't know the population of the towns, and I don't know the character of the sewage, and I don't know the character of that organic matter that is found in that water except by analyses from three to five miles above the mouth of the Illinois, so that I cannot answer that question conscientiously.

Q. Assuming that your chemical analyses are correct?

A. Yes sir.

Q. Can you conceive of any conditions existing above Grafton, along the Mississippi River, that would change the conditions which you draw from your conclusions, as to the potability of the water at Grafton?

A. I cannot answer that question as I said before.

Q. Why?

A. Because I am not familiar with those various conditions that I have stated, which I must study before I would be able to form a conclusion as to whether the Mississippi River is polluted before it reaches the mouth of the Illinois, by
2423 sewage from those cities. I don't know whether I can express an opinion.

Q. Have you any faith yourself in the conclusions which you derive from the chemical analyses above Grafton?

A. Yes, I am compelled to draw the conclusion from the analysis as I found it; how I find that water three to five miles above the mouth of the Illinois, in the Mississippi.

Q. And your conclusion is based upon the chemical analyses of the water at that point?

A. Yes sir.

Q. Can you conceive of any conditions existing above Grafton along the Mississippi River, that would make you draw a different conclusion from what you have, from the analyses that you made of the waters of the Mississippi above Grafton?

A. There are various possibilities, but I cannot draw any deductions from possibilities, where I am unfamiliar with the facts, upon which alone I could base a conclusion. Whether the Mississippi River when it reaches Grafton is polluted or not and what kind of pollution it might be I can only say. I found the water to be such as my analyses show, three and five miles above the mouth of the Illinois.

Q. Assume, doctor, that there was a population of 10,000,000 people emptying its sewage into the Mississippi from St. Paul down to Davenport, and your chemical analyses
2424 above Grafton showed you certain results which you have testified to here, would that condition make you draw any different inference from those analyses than you draw at present?

A. If this sewage from 10,000,000 people would all be discharged into the Mississippi River from one city, it is not likely that the sewage would ever purify itself in that river, and it is not likely that the water would be found in such a condition as I found it chemically from analyses of the samples taken three and five miles above the mouth.

Q. Assume that your analyses are correct.

A. Yes sir.

Q. And assume that 10,000,000 did discharge their sewage into the upper Mississippi, would the fact that they discharged their sewage into the upper Mississipp make you draw any different conclusion from your analyses, than you have drawn?

A. Well, I couldn't draw but one conclusion from the analyses, and that would be as I already stated, that the chemical character of that water is such, just as the analytical data enabled me to state.

Q. Then your conclusion as to the potability of the water above Grafton, does not depend upon the conditions that may or may not exist in the upper waters of the Mississippi, does it?

A. It must depend upon the conditions there which I am familiar with.

2425 Q. Don't your conclusions depend upon the analytical data of the waters above?

A. My conclusion that the water is potable or not potable in the Mississippi at the mouth of the Illinois, my conclusion is based on the analytical data. Whether or not that Mississippi River water, before it reaches that point, was polluted, and how it was polluted and where it was polluted don't come into consideration in my conclusion there. I only base the conclusion on the Mississippi River at the mouth of the Illinois.

Q. That is my question.

A. Yes sir.

Q. That your conclusion is arrived at from the analyses of the waters of the Mississippi at Grafton?

A. Yes sir.

Q. And the conditions that exist along the Mississippi River above Grafton, up to St. Paul, whether there are 10,000,000 people discharge their sewage into the Mississippi or not, wouldn't make you change your conclusions, would they?

A. It could not, because the conclusion is not based on those conditions.

Q. Then your conclusion from the analyses is, that the Mississippi River water at Grafton has become purified and potable during the months you have enumerated, is that right?

2426 A. I say it is potable at certain times.

Q. During the four months?

A. Yes sir.

Q. The water can only become potable by being purified, is that correct?

A. It may be potable without having been impure.

Q. But assume that it is impure; it would have to become purified before it would become potable, wouldn't it?

A. It must be in a certain chemical condition to enable the condition that is potable.

Q. Well, assume that it is in the chemical condition at the time you denominate it as potable, and previous to that point it was sewage contaminated, doesn't the conclusion of potability carry with it, the idea of purification for water of the character of that described?

A. No, water may be potable, and yet may not be pure.

Q. Can sewage contaminated water be pure?

A. A sewage contaminated water, no sir.

Q. Then if sewage contaminated water becomes what is known as potable, doesn't the condition of potability carry the idea of purification?

A. It doesn't carry the idea of complete purification, it only carries the idea of a purification to a degree.

2427 Establishing the water potable. That is permissible to be allowed for use for drinking purposes; that is potability.

Q. I understood you to say that the only chemically pure water was the laboratory water?

A. Yes sir.

Q. We are not talking about that water.

A. No sir.

Q. Now if the water of the Mississippi River at Grafton is potable, doesn't it convey to your mind as a chemist, that sewage discharged into that water at Minneapolis and St. Paul and all the cities nursing the banks of the Mississippi River, has become purified to the degree of potability by the time it gets to Grafton, the point where you made your examination?

A. Stating as I have done, that I am not familiar with the conditions, whatever pollution there might have taken place in that Mississippi River above the mouth of the Illinois River; whatever pollution has taken place, it has been rendered sufficiently harmless by the time that water reaches the mouth of the Illinois as to render that water potable during certain times of the year, as I have stated.

Q. That is the question I was after.

A. Yes sir.

Q. During the other eight months of the year, doctor, are the waters of the Mississippi River potable?

2428 A. They are more or less. That may depend upon certain conditions as found by the chemical analyses.

Q. Well, are they more or are they less?

A. I don't think that the impurities found during the other months of the year in the water taken from the Mississippi River a few miles above the mouth of the Illinois—I say I don't think that the impurities found at that time would very much affect the potability. There might be a slight increase in the impurities, and yet our analyses demonstrate that from a liberal standpoint, that water coming from the Mississippi River and subsequently mixing with the Illinois River, that it is on the whole potable water.

Q. I am speaking above Grafton.

A. Above Grafton; that's what I mean. I say that some parties might say that the water in the Mississippi River above Grafton is not potable.

Q. I want to know what you think.

A. My opinion is that practically throughout the year it is permissible as good drinking water.

Q. Doctor, assume that Grafton was a large city, and you were placed in charge of the water supply of that city as a scientific man, would you advise the citizens of Grafton to use the waters of the Mississippi River above the entrance of the Illinois River for drinking purposes during those eight

2429 months without boiling and without filtering, and denominate it a potable water?

A. I would consider that water from the Mississippi River potable.

Q. And would you so advise?

A. Yes sir.

Q. Then what did you mean in the beginning of this examination this morning, in stating that during the summer months, June, July, August and September, that the water in the Mississippi River above Grafton, was potable for that period?

A. Potable in the opinion and from the standards of all authorities that I know and that I recognize as authorities, but for the remaining months it may be that some parties would say, "Well, this water would not pass," but I would consider it as I said, from my standpoint, the liberal standpoint, I would consider that water potable throughout the year.

Q. Doctor, in giving your opinions here upon questions that are presented, are you giving us your personal information based upon your personal knowledge, or are you giving us the opinion of other men who have expressed themselves either in writing or in reports upon the subject matter of your testimony?

A. I am giving you first of all, wherever I can, my own
2430 personal judgment derived from either direct analytical work, and direct personal observations of conditions and direct personal study of various conditions prevailing at points where the information is necessary, and also from the study as is required of other chemists, the study of the literature published on the subjects, involved in the study of such questions.

Q. What literature have you consulted in regard to the potability of the waters of the Mississippi above Grafton, limiting it to the four months during the summer and excluding the other eight. Can you name the literature?

A. I have seen the standards formulated as regards the potability of waters when they have a certain amount of ingredients.

Q. I am speaking of the water, doctor, at Grafton, above the entrance of the Illinois River into the Mississippi?

A. I know of no literature that expresses a direct opinion on the potability of the Mississippi above the mouth of the Illinois. I mean general standards.

Q. Then when you testified that for the four summer months the water was potable, namely, June, July, August and September, as against the other eight, you were testifying and giving your individual opinion, were you, or the opinion of someone else?

2431 A. When I stated that I considered the water potable, absolutely for those four months, I meant that the amount of chemical ingredients found in the samples of water there are within the limits set by sanitarians and chemists as the limits of what would be potable and non-potable water. It comes within all those limits of responsible authorities. For the remaining months there might be a difference of opinion. Some sanitarians might say as I have stated in my standard that I have published, such a book or such a report, I would consider these limits beyond, I would consider the quantity of these ingredients beyond those limits, but there are only a few of those. On the whole I think that sanitarians will agree with me, with my personal opinion, that practically throughout the year the Mississippi River at points three and five miles above the mouth of the Illinois, is potable.

Q. Doctor, you stated that you were a specialist on bacteriology and chemistry. Do you know of any bacteriologist that holds to the doctrine, that any running stream, sewage polluted, is potable water?

A. First of all, I didn't state that I was a bacteriologist. I said I was a chemist and that—

Q. You employed bacteriology in your work?

A. I consider it my duty to familiarize myself with much of bacteriology as is a part of the chemistry of water.

2432 Q. And in your investigation and in order to equip yourself as a chemist, you deemed it necessary to qualify yourself to a certain extent in bacteriology.

Q. Now do you know any bacteriologist of any recognized standing that adheres to the doctrine that a stream or river sewage polluted is potable water?

A. There are scientists—

Q. No, I am talking about bacteriology.

A. Yes, there are scientists that maintain the opposite views.

Q. Who are they, doctor?

A. Well, there are a number of them. They are principally German investigators.

Q. Do you know any that have given the question of running streams any consideration that hold that view?

A. That running water purifies itself?

Q. No, that streams sewage polluted by cities nursing their banks, are potable water?

A. Yes, there are some.

Q. Well, who are they?

A. Well, I cannot think of any just at this moment.

Q. Do you adopt their views?

A. No sir.

2433 Q. Are you opposed to their views?

A. I think that the weight of the evidence from the other side in opposition to those views is so strong, that from a careful study of those views, I would accept the views of those that are opposed to the views that you quote as correct.

Q. That is, that the bacteriologists who hold that sewage polluted streams are not potable water, the views of those learned men, meet with the approval of your judgment, is that right?

A. Yes sir.

Q. Now supplementing your investigations as a chemist, with the views of bacteriologists that hold that running streams sewage contaminated, are not potable, do you still adhere to the opinion as a chemist and bacteriologist that the waters of the Mississippi River are potable during a greater part of the year?

A. Why my chemical analyses demonstrates the potability of the Mississippi River water at the mouth of the Illinois.

Q. Doctor, when you are in doubt as a chemist, you remove that doubt, do you, if possible by the aid of bacteriology, if it will remove it?

A. Well, I take into consideration a bacteriologist's views.

Q. And if those views create a condition or supplement a
2434 condition that chemistry fails to disclose, you combine the
two and draw a conclusion, do you not?

A. That depends upon the question involved. If it is one of chemical importance I disregard it.

Q. Take the question of running streams, sewage polluted, you say you accept the views of the bacteriologist that running streams, sewage polluted are not potable? Am I correct in that statement?

A. As applied to the great majority of cases investigated.

Q. Do you make the upper Mississippi an exception to the rule?

A. I cannot make it an exception to the rule, but as long as I am not familiar with the conditions prevailing there, I have no right to apply the rule, any rule, to the conditions existing in that river.

Q. Aside from the Illinois River and the Mississippi River from Grafton, do you apply that rule to any other river or rivers in the world, of the bacteriologists?

A. From a study of conditions of some of the river waters which I have analyzed, I have formed conclusions, taking into consideration the results of bacteriological investigations as well as chemical investigations.

Q. And did you arrive at the potability of the water?

A. Yes sir.

2435 Q. From chemistry or bacteriology?

A. Well, principally from chemistry, but I found that bacteriology supplemented in a measure, the chemical results, so that a conclusion could be formed taking into consideration the bacteriological views.

Q. Now, doctor, if a stream was disclosed to be chemically pure and bacteriologically infected, which conclusion would you follow, a chemical test or a bacteriological test, in arriving at the potability of the water?

A. You say if the water would be chemically pure, and bacteriologically—

Q. Yes, I mean chemically potable. I am not using, when I say "pure" the laboratory purity; I am using purity as defined by you as to potable water?

A. That is confined to the chemical feature of it?

Q. Yes?

A. And adding thereto—

Q. The bacteriological view. If a stream was discovered to be chemically potable, by the aid of chemistry and bacteriology, and contaminated by the aid of bacteriology, what would be your view as to the potability of that stream as a scientific man who has made researches into both fields of learning?

A. It might be bacteriologically impure.

2436 Q. That is an argument?

A. Well, no researches have shown that may be the case.

Q. Now what are your conclusions as a scientific man from the situation such as presented to you by the question, as to whether waters are potable or not?

A. The chemical conditions are usually such in a polluted river that they bear out the bacteriological conditions, and the bacteriological conditions may bear out the chemical conditions, of a sewage polluted river. They usually go together—both pollutions.

Q. I want to ask you a question, doctor, in order to be fair. Are the conditions which I have given in the hypothetical question I propounded to you an unfair hypothesis and inconsistent with the conditions that might exist?

A. Well, there is no limit to the possibilities of the conditions existing.

Q. Well, are they inconsistent, I mean?

A. Well, it is not to my knowledge, that I know, where such conditions exist as you mention.

Q. Then the question is a fair assumption?

A. Well, it is a hypothetical question.

Q. It is a fair assumption; it has nothing that is contradictory in itself, has it?

A. That may be possible.

2437 Q. Now if a condition of that character presented itself to you where a stream was chemically potable and bacteriologically contaminated, what would be your opinion, Dr. Teichmann's opinion as to the potability of the water?

A. If such a condition should exist—I don't know of any—if it should exist, that water would certainly from a general hygenic standpoint, not be considered potable, because the bacteriological pollution would certainly stamp it as unpotable, as not potable.

Q. Then if you accept the authorities in bacteriology that all sewage contaminated streams are not potable, and your analyses disclose the potability of the stream, how can you arrive at the conclusion that a running stream, sewage contaminated becomes potable?

A. The potability there from a general hygienic standpoint—the question of potability will depend upon both the chemical and bacteriological conditions as found.

Q. But assuming that the authorities that address themselves to your intelligence with approval, hold to the doctrine that sewage contaminated streams are not potable, notwithstanding that chemical analyses disclose the potability of the stream. How can you reconcile your position that a running stream such as the Mississippi River above Grafton is potable during the year?

2438 A. The analytical results from the water as I have studied them, the water of the Mississippi River found a few miles above the mouth of the Illinois, allow of no other conclusions than that the water is potable.

Q. Then you eliminate from your conclusion all considerations of the opinion of experts on bacteriology which you adopt in arriving at that conclusion, don't you?

A. I do not, because the study of bacteriological reports on the water from that point, do not justify me in forming a general conclusion from a general hygienic standpoint, a conclusion that the water found in the Mississippi River above the mouth of the Illinois is unpotable. There is no bacteriological evidence to show that it is unpotable from a general hygienic standpoint in conjunction with the chemical potability found.

Q. Then the principle as held by the bacteriologists whose opinions you say you approve is not attainable when applied to the Mississippi River above Grafton as to the non-potability of running streams sewage contaminated?

A. I do not draw that conclusion from my statement.

Q. Isn't that a fact?

A. I cannot draw such conclusions because I haven't made any statement wherein such a conclusion was given.

Q. You approve of the opinions of experts and bacteri-
2439 ologists that hold that all sewage contaminated streams are not potable, don't you?

A. I said that the potability of the water as determined by careful investigation chemically and bacteriologically show that, that from a general hygienic standpoint we can only determine the potability by taking into consideration both factors, chemically and bacteriologically.

Q. Isn't there a class of learned bacteriologists who hold to the view that sewage contaminated rivers are not potable?

A. Yes sir.

Q. Did you not state, doctor, that you adopted those views?

A. I said that the weight of the investigations—

Q. I want to get at what you think, not the weight?

A. The weight of the opinions is favorable to that side, which considers sewage contamination of waters a serious problem.

Q. Well, in adjudicating the opinions of different men and arriving at a conclusion as to the weight of evidence, do you Dr. Teichmann, adopt the principle of those men who hold that sewage contaminated streams are not potable?

A. I do adopt it for all causes where general conditions as I have repeatedly mentioned today, are favorable to the application of such a rule, but they are not favorable to every case.

2440 I do not accept it as a hard and fast rule for every possible case, disregarding entirely the various conditions that should come into consideration.

Q. Do you know of any reason or condition that exempted the Mississippi River from Grafton to St. Paul from being within that rule, if so, what are they?

A. No sir.

Q. Why not?

A. It is possible that the rule may be applicable to the Mississippi River above Grafton, providing that the conditions prevail that will justify its application.

Q. Do you know whether those conditions prevail or not?

A. I don't know, as I said before.

Q. Then if you don't know, why do you make the Mississippi River an exception to that rule that you have accepted?

A. I don't make it an exception. I don't form an opinion.

Q. Does the Mississippi River come within the rule?

A. That is what I cannot tell unless I make an examination of the conditions necessary to form an opinion.

Q. And then not knowing whether the conditions obtain or not in the Mississippi, and being unable to express an opinion as to whether the Mississippi River is an exception to the rule or within the rule, how do you come to the conclusion that the waters of the Mississippi are potable unless you eliminate from your opinion all consideration of bacteriology?

2441 A. The question in this case is not involved, "What are the conditions in the Mississippi above the mouth of the Illinois miles and miles away." I only base an opinion on the conditions as I find them three and five miles above the mouth of the Illinois.

Q. Are you testifying as an expert upon the facts that only apply to this case, doctor?

A. I am testifying to the facts as I found them at the mouth of the Illinois River. What the conditions are hundreds of miles above the mouth of the Illinois on the Mississippi I am not considering. I only ascertained the character of the Mississippi River water three and five miles above the mouth of the Illinois. Is it good or bad? And I find it potable, and I have so expressed it. What it might have been miles and miles above the mouth of the Illinois, is immaterial to my mind in considering the questions involved in the investigation that I conducted these years.

Q. As far as the effect upon this case one way or the other, you don't take that into consideration, do you doctor?

A. Well, it is a question of cause and effect. I find the effect there at the mouth of the Illinois River.

Q. Get my question. As far as the effect it might have upon the determiation of this law suit, you don't take that into consideration in giving your opinion, do you?

2442 A. No. I am only to find out what the character of the water is, of the Mississippi before it meets the Illinois. What it has been miles and hundreds of miles above the mouth of the Illinois, is immaterial in determining the question, "How is the water at the mouth of the Illinois?"

Q. Then as far as your opinion goes to the potability of the water at the mouth of the Illinois, you haven't taken into consideration the bacteriological view of the situation have you?

A. Yes sir, I have.

Q. And have you given it any consideration, any weight, in arriving at that conclusion?

A. Yes sir, I have.

Q. And in view of the fact that you are unable to state what the conditions of the Mississippi River are above Grafton bacteriologically, whether it is the exception or within the general rule, that all sewage contaminated waters are not potable, still you adhere to the opinion that you take into consideration the bacteriological view as well as the chemical, and arrive at the conclusion that the water is potable?

A. Yes, I have examined both conditions chemically and bacteriologically and thereupon formed a conclusion that the
water of the Mississippi is potable, three and five miles
2443 above the mouth of the Illinois.

ADJOURNED until 2:00 P. M. same day, March 31, 1903.

2444 Southern Hotel, St. Louis, Missouri. 2:00 P. M., Tuesday, March 31, 1903. Continuation after recess. Present, the Commissioner, and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMMANN,

resumed the stand for further cross-examination by Mr. Todd and testified as follows:

Q. When did you personally make a bacteriological examination of the waters of the Mississippi at the point indicated in your last answer?

A. I did not make a personal analytical examination. What I meant was that I examined reports—

Q. Well, that is all I want, doctor.

A. Yes.

Q. Did you personally make a bacteriological examination of the waters of the Mississippi three or four miles above Grafton?

A. No sir.

Q. Then upon your personal knowledge, you don't know whether the waters at that point were bacteriologically pure or
not, do you.
2445 A. Well, if you mean personal knowledge based on original analytical researches, I would say "No."

Q. That is what I mean, what you, yourself know?

A. Well, based upon original researches, analytically, I would say "No."

Q. Then what information you have as to the bacteriological condition is based upon what other people have told you and not upon what you yourself know from personal analytical researches, is that correct?

A. From what has been reported by bacteriologists who made examinations at that point.

Q. Now excluding the opinions of everybody and basing your opinion upon your personal knowledge, can you say that the waters of the Mississippi River three miles above Grafton are potable, bacteriologically and chemically?

A. Not if based upon personal analytical investigation of my own.

Q. That is all I want, is your own knowledge.

A. Yes.

Q. So that when you testify as to the potability of those waters, your answer is based upon your personal researches as a chemist?

A. Yes sir, and upon the study of reports.

2446 Q. As a chemist—and you have no personal knowledge from personal investigation as to the bacteriological conditions that prevail at that point, have you?

A. Not as far as personal analytical researches is concerned.

Q. Now, if the information that comes to you second-hand is inaccurate, or not properly founded, your opinion based upon hearsay would not be an opinion that you would put a great deal of credence in, would it?

A. If the bacteriological information that I base the final conclusion on is erroneous, I would certainly modify my views accordingly.

Q. Have you any opinion of bacteriological experts, whose opinion you deem worthy of belief, that hold that the waters of the Mississippi above Grafton are potable waters?

A. The information that I have—

Q. No—opinion of bacteriologists, of accepted standing, whose opinion you adopt, that hold that the waters of the Mississippi above Grafton, are potable?

A. Well, I have the analytical report—

Q. I want the opinion?

A. Of a scientist from which I draw my conclusions—

Q. Now doctor, I didn't ask for reports; I ask you have you any opinion or do you know of any opinion of any bacteriologist who holds that the waters of the Mississippi
2447 above Grafton are potable, and whose opinion you accept?

A. Well, that opinion is embodied in the analytical report as I studied it, from which I draw that conclusion.

Q. I am not asking you for reports. I want the conclusions of a bacteriologist who has made the analytical investigation, who concludes from his analytical investigations that the waters of the Mississippi are potable, and whose opinion you approve.

A. Well, I have no definite conclusion to that effect, because I formed my own opinion from the study of analytical data.

Q. Then you know of no bacteriologists whose views you accept that hold that the waters of the Mississippi are potable above Grafton?

A. No, I form my own opinion from the data.

Q. I didn't ask you about your opinion, doctor?

A. Well, I answer that question "No."

Q. You do not?

A. No.

Q. And notwithstanding that fact and the fact that you personally have never made a bacteriological survey of the waters of the Mississippi above Grafton, you still hold to the opinion that the waters of the Mississippi are potable?

A. From the study of analytical data of the bacteriol-
2448 ogical investigations—

Q. Can't you answer that Yes or No?

A. (Continuing)—I feel justified in answering that question Yes.

Q. Then is it not a fact, doctor, that bacteriologists have condemned the waters of the Mississippi above Grafton?

A. Not to my knowledge.

Q. Is it not a fact that Dr. Ravold, the bacteriologist, a recognized authority in St. Louis upon bacteriology, condemned the waters of the Mississippi as not being potable?

A. Not to my knowledge.

Q. Didn't you hear his testimony here?

A. I heard some of his testimony, but I didn't hear him testify to that fact, that is, in general conclusion.

Q. Assuming that he did so testify, would that have any effect upon your conclusion as to the potability of the waters of the Mississippi at Grafton?

A. I would base my final conclusion on the study of analytical data that have been obtained from bacteriological investigation of the water at that point.

Q. Then you would not regard the opinion of a man who has given this question a great deal of study, as having any weight upon you in arriving at a conclusion as to the potability of the waters of the Mississippi, bacteriologically?

2449 A. I woud give considerable weight to the conclusions of a bacteriologist upon certain analytical data that he is investigating or from which he is drawing his final conclusions, but I would not accept his conclusions unless I would have convinced myself by a personal study of those very analytical data whether in my opinion, when judging the general potability of a water, whether his conclusion would conform with my final conclusion, from a general hygienic standpoint.

Q. Have you given any personal consideration to the bacteriological examinations of the waters of the Mississippi River above Grafton?

A. I have studied the analytical data which were at hand.

Q. Above Grafton?

A. At the point several miles above Grafton.

Q. And were those analytical data sufficient to enable you to pass upon the potability of the waters of the Mississippi for twelve months in the year?

A. These—

Q. Answer the question, doctor, Yes or No?

A. These data were sufficient to my mind—

Q. Yes?

A. To enable a general conclusion from a hygienic standpoint—

Q. To enable you to pass upon the potability of the water of the Mississippi above Grafton for a period of one year?

2450 A. Yes sir.

Q. Covering what period of time were the samples taken from which the data to which you refer were made?

A. They were taken from September, 1899, until October, 1900.

Q. Every day?

A. No sir.

Q. Every week?

A. For about eight months, the samples were collected every day.

Q. And did you make the examination?

A. No sir.

Q. Are you qualified to make examinations bacteriologically?

A. Well, not in general.

Q. Just answer it Yes or No, doctor?

A. Well, no; I say no.

Q. Do you know anything about the reliability of the data except what you get from hearsay?

A. Well it is a matter of personal judgment.

Q. Well, a man could go down there and look at the water, couldn't he, and have a personal judgment as to whether it is bacteriologically free from sewage or not, couldn't he?

A. No sir.

2451 Q. He could not?

A. No sir.

Q. If he has no personal knowledge of the analyses, what is the difference between his position in passing judgment and if he is not competent to examine bacteriologically, what is the difference between passing a judgment in that way—than it would be to have somebody tell him that the waters are not impure, and for him to form an opinion from what somebody told him?

A. Well, he must be able to judge whether the analytical data obtained by personal analytical investigation by another man, whether they have the character of reliability, so that in studying these data that he can himself form an opinion on the data collected by others.

Q. Is there anything in the data itself that shows whether it is reliable or not?

A. Well, it is again a matter of personal judgment.

Q. Is there anything in a personal judgment that will enable a man to tell whether the data is reliable or not, if he is unable to make the analyses himself?

A. Well, he can go very much by the opinion, and the character, and the education and the experience of the man who collected the data.

2452 Q. Then you are adopting the opinion of the man who collected the data instead of the data itself, are you not, doctor?

A. As far as the methods of collecting is concerned, yes sir.

Q. As far as the integrity of the data as derived from analyses bacterially speaking, you have got to rely upon the man who made it?

A. Yes sir.

Q. So that it comes right down to the point that you have got to accept the judgment of some other man before you can pass a judgment yourself, isn't that right?

A. In a measure, yes.

Q. Well, isn't that in a full measure?

A. Well, he won't form an opinion blindly; he will examine those data and from the general course pursued in obtaining those data, together with the personal opinion that he has of the reliability of that man as a scientist, to conform to the opinion.

Q. Well that would leave it to the man's judgment, wouldn't it?

A. Yes, that altogether would make up the judgment.

2453 Q. And all that you have got when you get through with what you have stated, is the judgment of the man himself who made the data?

A. As far as the data themselves are concerned, yes sir.

Q. If I should hand you some data and you did not know the man who made it, could you tell whether the data was correct or not, by the data itself?

A. Well, I may not know him personally, but I may know of him.

Q. No, I don't tell you who made the data. I give you the data made by an unknown, all that you have before you is the data itself, can you look at the data and tell whether that data is to be relied upon or not?

A. I could not, because it would be unfair. The data may be entirely wrong; they may not have been honestly collected, etc.

Q. Then you have got to rely upon the honesty, the ability and the carefulness and experience of the man who collects the data before you can predicate an opinion upon his judgment?

A. Yes sir, I should.

Q. And all that you have that is anyways tangible to base your opinion on is the judgment of the man whose judgment you respect; is that right?

A. Yes sir.

2454 Q. If that man is wrong in his conclusions and analyses, you are wrong in your conclusions, are you not?

A. Not in all cases. He may draw different conclusions from the very data than I would draw—

Q. And by the data to which you are speaking—was that the data that Dr. Ravold introduced in evidence here in connection with his testimony?

A. Yes sir.

Q. Do you draw different conclusions from those of Dr. Ravold?

A. As far as I know, I have drawn certain conclusions from those data which are my own conclusions.

Q. And if Dr. Ravold draws the conclusion from those data that all streams sewage polluted are not potable water or that the Mississippi River, which is sewage polluted, is not a potable water, you disagree with him in his conclusions?

A. I do not disagree with him as far as the application in many cases may be concerned.

Q. I am speaking of this particular case?

A. Well not in general, as I said this morning, I do not draw a hard and fast rule as to this question; it all depends upon local conditions surrounding, in bringing about these questions; they have to be taken into consideration.

2455 Q. Then I say, if Dr. Ravold, up at Grafton, should draw the conclusions from the analytical data which you have inspected, that running water in the Mississippi River which is sewage polluted, is not a potable water during twelve months of the year, you differ with him?

A. If Dr. Ravold meant to apply that to every case analytically—

Q. No, I mean at Grafton.

A. At Grafton as compared with the chemical results, I have already stated that from a general hygienic standpoint, I would consider the Mississippi River water potable.

Q. Doctor, I didn't ask you what you considered?

A. I never considered it alone.

Q. I ask you if Dr. Ravold drew the conclusion that the waters of the Mississippi River were not potable, from the data that you say you have inspected and analyzed, do you differ with him as to his conclusions? Can't you answer that Yes or No?

A. Well, that depends upon the point to which he applies this conclusion.

Q. At Grafton; at the point where the samples were taken, at Grafton?

A. I formed my conclusions—

Q. I didn't ask you that doctor. Do you understand my question?

2456 A. Yes sir, I do.

Q. Then, can't you answer it?

A. I am begining to answer it.

Q. The question is whether if Dr. Ravold drew a conclusion from the data that you say that you have inspected—

A. Yes, I have.

Q. Up there at Grafton, that the water of the Mississippi was not potable, do you differ with him in his conclusions from that data?

A. According to my opinion that the water is potable at Grafton, I do.

Q. You do?

A. Yes sir, I do, viewed from a general hygienic standpoint.

Q. You differ with him then as to his conclusions based upon that data as to the potability of the water?

A. I would from a general hygienic standpoint.

Q. Yes, that is all I wanted to get there. Now doctor, how does that condition of potability bacterially, and chemically obtain four miles above Grafton in the Mississippi River—what is the cause of it, and to what is that condition attributable?

A. That I could only say by an investigation of the character of the Mississippi River during its entire route from 2457 the point where it starts, down to the mouth of the Illinois, which investigation I have not made.

Q. Well, if it should appear that the sewage of St.Paul and Minneapolis and all the other cities above Grafton empty their sewage into the Mississippi River, and that that sewage came from a great many thousands of people, how could you explain the potability of the water at Grafton during the entire year, if those facts, which are assumed, are facts?

A. I would not express an opinion except by my personal investigation of the analytical data that might be presented to me from reliable chemical authorities on the character of that water above a point from where I took the samples.

Q. Well, assuming that this sewage goes into the water?

A. It would still be impossible to answer that question without taking into consideration—

Q. Can you give any explanation from a scientific standpoint why it is that you find the water above Grafton potable during the year?

A. I have not during that investigation given that question any consideration because I did not feel called upon to answer the question.

Q. Why?

A. The question was not involved in the investigation 2458 as outlined by the authorities for whom I carried on this investigation. I was only to ascertain the character of the Mississippi River water a few miles above the mouth of the Illinois River. That was all.

Q. So that you are unable to give an opinion or to express a reason why the sewage contaminated waters of the Mississippi are purified and rendered potable during the entire year, when it reached three miles above Grafton?

A. It would be unfair for me to give an opinion on that question without personal investigation and study of analytical data.

Q. You have no opinion then as to how this condition above Grafton is obtained?

A. Nobody could form a fair opinion.

Q. I am not speaking of anybody doctor, I am asking for Dr. Teichmann's opinion?

A. Well, I have no opinion.

Q. You have no opinion?

A. On that subject.

Q. And the situation that presents itself of the potability of the water above Grafton, is a condition that you have no explanation in your mind to offen for?

A. I didn't study it and therefore have no opinion to express.

2459 Q. Have you any ideas on the subject, doctor, as to why that water is potable for the year around, above, Grafton?

A. I would not form any ideas without a thorough investigation.

Q. Does the theory that running waters purify themselves of sewage contamination, running over the course from St. Paul down to Grafton, appeal to your judgment as an experienced man upon water-courses?

A. I could not express an opinion without previous investigation.

Q. Now doctor, have you examined—what is the condition of the waters of the Missouri River above its mouth, as to potability?

A. I consider the water potable at Fort Bellefontaine, the station in the Missouri river where we collected samples of water.

Q. Where is Fort Bellefontaine, doctor?

A. Bellefontaine is five miles above the mouth of the Missouri.

Q. Is that water potable all the year around?

A. More or less potable all the year around?

Q. Is it more or is it less?

A. That varies according to the seasons.

2460 Q. Now when you use the word potable, do you compare the word "potable" as "potable," "less potable" and "least potable" or do you classify it as "potable" or not "potable?"

A. In general I would classify it as potable or not potable; but the potable water may differ very much in its degree of potability. One water may be much better than another water and both may be potable.

Q. During a year how many months of the year are the waters of the Missouri potable and how many months of the year are the waters of the Missouri not potable?

A. I would consider the water found at Fort Bellefontaine station potable throughout the year.

Q. Throughout the year?

A. As I said, to a varying degree.

Q. Are you acquainted with the cities that empty their sewage into the Missouri River above Bellefontaine?

A. Somewhat, yes sir.

Q. Will you name to me the cities that empty their sewage into the Missouri River?

A. You mean all the cities that empty their sewage into the Missouri River?

Q. Yes?

2461 A. I could not give you that list, because there are a great many. It is a very long river.

Q. Well, beginning at Sioux City, that empties its sewage into the Missouri, does it not?

A. I believe it does.

Q. Omaha empties its sewage?

A. Yes sir.

Q. Omaha has large packing industries there, has it not?

A. Yes sir.

Q. And large distilling interests in Omaha?

A. Yes sir.

Q. And across the river from Omaha is the town of Council Bluffs, which is quite a manufacturing town, is it not?

A. I understand it is.

Q. They empty their sewage into the Missouri River do they not?

A. I believe they do, yes sir.

Q. And coming down a little bit further, is the town of St. Joseph or St. Joe; that empties the sewage into the Missouri River, does it not?

A. Yes sir.

Q. And Leavenworth, Kansas, quite a large city, empties its sewage into the Missouri?

A. Yes sir.

2462 Q. And Atchison also, and Kansas City?

A. Yes.

Q. That is a city of considerable size, is it not?

A. Yes.

Q. Great industries in the packing business, and slaughtering business there?

A. Yes sir.

Q. It has distilleries too?

A. Yes sir.

Q. And other manufacturing institutions, and the sewage of that city empties into the Missouri?

A. Yes sir.

Q. And then the towns that lie along both sides of the River in Kansas—

MR. JEFFRIES: I object to all the questions and move that they, together with the answers thereto be stricken out as far as the same refer to the emptying of the sewage of the various cities into the Missouri River, for the reason that the same is incompetent and irrelevant, and has no bearing upon the controversy here involved, and for the further reason that those towns situated upon the Missouri River discharge their sewage into a natural water flow, and flow into the water shed tributary to the Missouri River, while the question here involved, is that the sewage from Chicago is carried over 2463 from one watershed into another from the Chicago River or Lake Michigan rather, into the watershed of the Illinois River and thence into the Mississippi.

Q. And then the towns that lie along both sides of the river in Kansas, and the tributaries of the Missouri, empty their sewage into the Missouri River, do they not?

A. Yes, some do.

Q. And the sewage of Jefferson City, the pride of Missouri, empties its sewage into the Missouri River, does it not?

A. Yes sir.

Q. Now, doctor, are there any other cities that you know that I have not enumerated that empty their sewage into the Missouri River?

A. Yes sir, I think you have ommitted Herman, Missouri and St. Charles, Missouri.

Q. Doctor can you explain to me why the Missouri River at Bellefontaine is potable when all these cities and towns that have been mentioned here empty their sewage into the Missouri River?

A. First of all it depends very much upon the amount of sewage which these cities discharge into the Missouri River. It depends furthermore upon the volume of water in the Missouri River. It depends also upon the velocity of the flow.
2464 It depends also upon the general conditions of the course of the Missouri River; it depends largely upon what accessions of soil in the form of clay and silt the Missouri River takes up along its winding course, with innumerable curves and bends, drags along into the river, and what effect sedimentation of this enormous quantity of soil which is by the erosions of the land carried into the water will have on the sanitary character of that water.

Q. Doctor, does a stream running east and west purify itself any better than a stream running north and south?

A. I do not see any difference there.

Q. What conditions obtain in the Missouri River for its purification that do not obtain in the Mississippi River above Grafton?

A. The Mississippi above Grafton I am not familiar with except at a point from three to five miles above the mouth of the Illinois, so I could not make a comparison there.

MR. JEFFRIES: We object to the question for the reason that it is incompetent, irrelevant, and has no bearing upon the case.

Q. MR. TODD: What conditions obtain in the Missouri River that do not obtain in the Illinois River?

A. There are various conditions. The volume of water in the Missouri River is generally larger. The course that the Missouri river takes is one of a great many bends and 2465 curves, much more so than the Illinois River does. The quantity of suspended matter as found by the analyses of the waters from the two rivers is much larger in the Missouri River than it is in the Illinois River. There are, as I have already said, enormous accessions of soil swept along the course of the river from the shores of the river into the Missouri River. This is not the case in the Illinois River.

Q. What effect has suspended matter in water upon the purification of sewage pollution?

A. That depends very much upon the character of the suspened matter.

Q. Does clay in suspension act as a purifier?

A. Heavy sediments of clay will produce at such points along the river where the velocity is slow along the shores of the river and not in the channel, will produce—particularly if there are many bends and curves, considerable sedimentation along the banks. The Missouri River is a river that is very poorly regulated; it is a river whose banks often over-flow.

Q. What do you mean by poorly regulated, doctor?

A. Well, I mean by the Government; it is a river that is practically being abandoned, and there is considerable overflow at times of high water and this overflow will cover vast areas of land sometimes.

Q. Does that help the purification?

A. Yes sir, it does.

2466 Q. In what way?

A. Because sedimentation according to the accepted axiom of modern science will assist materially in purification.

Q. What is the area of the land overflowed by the Missouri River that you take into consideration as affecting this purification by the process of sedimentation?

A. I cannot give you any accurate data on that point.

Q. Can you approximate it?

A. No sir.

Q. Where, along the Missouri River do those conditions prevail?

A. They prevail from my own observation along the Missouri River between Kansas City and St. Louis.

Q. The entire course?

A. Well I haven't examined the entire course, but at such points where I examined it I personally convinced myself of it.

Q. And to what extent, how far from the thread of the stream does the river overflow?

A. Well, that varies greatly.

Q. Well, approximately as you observe it?

A. I have seen at places along the route of the Missouri River, I have seen as much as 40 or 50 acres overflowed 2467 on one side of the stream.

Q. Have you ever seen as much as ten square miles overflowed?

A. Not to my recollection.

Q. Between Kansas City and St. Louis?

A. It might have been more than ten square miles that I have seen, but I couldn't say positively that it was that much.

Q. Well, how many acres do you think it was?

MR. JEFFRIES: Forty or fifty acres at many places.

MR. TODD: Forty or fifty acres that you saw overflowed, would that assist to any material extent in the purification of the Missouri River?

A. Since these conditions prevail all along the route between Kansas City and St. Louis, from information that I have I should think it would have a considerable effect.

Q. Do you consider that a great effect in the purification of the Missouri River—these sedimentation beds operated by the overflow of the banks?

A. Yes sir.

Q. In what way doctor, does that obtain. Just describe how that is effected?

A. Simply that these periods of rises, causes the water when it overflows like that on its banks, the velocity is reduced considerably. At some places these points of sedi- 2468 mentation are covered with water that stagnates for some time, and the natural processes of sedimentation there will drag down to the bottom of those sedimentation beds, a great deal of organic matter and this organic matter will undergo nitrifying processes of purification more rapidly because of nitrifying organisms, so-called bacteria, that perform this oxidation work in the soil.

Q. Is there anything that you regard as beneficial in the purification of the Missouri River in these overflow places for sedimentation?

A. I consider them beneficial.

Q. Is there anything else more beneficial for the purification of that stream than that?

A. There may be additional benefits from the general chemical character of that stream between Kansas City and St. Louis.

Q. Has it got a general chemical character peculiar to itself?

A. It has a character of great stability.

Q. Is that a chemical characteristic,—stability?

A. Yes I should define it as such.

Q. What do you mean by stability, doctor?

A. Stability, in contradistinction from instability, would
2469 be that the processes of purification have reached the
stage where the final product of the nitrifying cycle, that is, the oxidation of the free ammonia to nitrites, and nitrites to nitrates, has reached a stage so that it is largely completed, as is always evidenced in the Missouri River between those points that I have mentioned, by low nitrites, and uniformly low nitrites between Kansas City and St. Louis and comparatively high nitrates.

Q. Doctor, do you know how far below Sioux City, after the discharge of the sewage from Sioux City, the water becomes purified and potable?

A. No sir.

Q. Do you know how far below Omaha, and Council Bluffs the water becomes purified and potable after the sewage has been emptied into it?

MR. JEFFRIES: I object to all questions of that character for the reason that they are incompetent and irrelevant and have no bearing on the issues in the case.

MR. TODD: How far below Council Bluffs and Omaha, do the waters of the Missouri become purified and potable after the sewage is emptied into it at those places. Do you know?

A. As regards the point of purification; that question could not be answered.

Q. Why, doctor?

2470 A. Because the conditions are such in the river that while the water in the channel below Omaha might show certain chemical improvements after the sewage of Omaha has been discharged into the river, the water running along the shore line wouldn't show that to that extent.

Q. Why?

A. Because it is a well known fact that the sewage as it is discharged into the rivers, in most of the cities, is discharged on the shore, right from the shore. It flows along the shore where there is supposed to be a current of less velocity than the current in the channel, and this sewage may appear in this shore water, the shore current, whereas the channel current is entirely different water.

Q. It ultimately gets into the channel, doesn't it?

A. Until at high stages of the river when flood water comes down. It is a matter of course that the flood water will sweep out and push out the organic matter that has been in a more quiescent state along the shore and sweep it out into the channel and that will bring higher results again.

Q. Wouldn't the serpentine course of the Missouri River serve to get the sewage into the channel?

A. Well now, it has been demonstrated by careful investigation—

2471 Q. I want to know what you think, doctor, not anybody else.

A. Well, not necessarily, no sir.

Q. It would not?

A. No sir, my observations—

Q. Wouldn't that be purified twenty miles down from Omaha?

A. That would be impossible for me to say because of the facts that I have mentioned.

Q. What are they?

A. The conditions that the sewage may run along the shore current and take some time before flood water may sweep out the sewage and flush it into the channel. As long as that stream of flood water wouldn't come, the channel water may show an entirely different chemical character than the shore water.

Q. Well, if it remains along the shore, say for a week, wouldn't the process of purification take place?

A. That is hard to tell; it might take months.

Q. As a kind of septic tank?

A. It might take months.

Q. Months?

A. Yes sir.

Q. Wouldn't all the impurities be destroyed before a month?

A. No sir, not necessarily; it would depend upon the character of the sewage very much, that would be discharged 2472 into the river.

Q. If the sewage should be placed into the channel would it take any longer to purify it in the channel than it would along the shore on the banks?

A. Sometimes it would and sometimes it wouldn't. It depends upon the conditions.

Q. Why, and what conditions?

A. Because it would depend somewhat upon the character of the water and it would depend upon the velocity of the stream, and it would depend upon the character of the sewage being flushed from the shore into the channel.

Q. Well, assuming that the same condition of water exists in the channel as exists along the shore, and assuming that the same sewage that was placed along the shore was placed along the channel, would the fact that the sewage entering the channel serve to purify it any quicker?

A. It is not likely—

Q. Than it would along the shore?

A. It is not likely that such a condition would prevail.

Q. Assume that it does prevail.

A. All investigations show that it does not.

Q. What?

A. All investigations and researches by scientists show 2473 that such a condition does not prevail.

Q. We will assume that it did prevail.

A. Well, what then, if I may ask.

Q. Would the sewage purify quicker in the channel than it would along the shore?

A. No sir, it would not.

Q. And what are the conditions along the shore that prevents the purification of sewage, that do not exist in the channel?

A. I say that the conditions along the shore are usually, not always more favorable to a gradual purification of the sewage, than they are in the channel.

Q. Then, if the sewage of Omaha entered the channel in any way, it would take how long for it to purify?

A. That is a difficult matter to determine.

Q. Would it take thirty days?

A. I couldn't say.

Q. Well, if it takes thirty days along the shore, and the conditions along the shore are more favorable for its purification than in the channel, it would take longer in the channel wouldn't it, than it would along the shore?

A. I couldn't say.

Q. Why, doctor?

2474 A. Because there are so many conditions to be considered that I cannot determine that point.

Q. Well if the conditions were the same, wouldn't the sewage in the channel take longer than along the shore?

A. It would take longer for the sewage in the channel to purify than it would if it remained in a quiescent state on the overflowed banks along the shore.

Q. What conditions exist in the channel of the Missouri River that would facilitate the purification of the sewage?

A. The conditions in the channel of the Missouri River are such that usually when the sewage of the cities is flushed into it into the channel, that it has previously undergone a certain stage of preliminary purification along the shores in the sediment of the banks which are overflowed at those points in this poorly regulated river.

Q. Do you know that as a fact, doctor, or as a theory?

A. Well, the general character of the river proves that.

Q. Do you know that statement to be a fact or a theory?

A. That conclusion is justifiable from the chemical character.

Q. I didn't ask you about whether the conclusion was justifiable or not. Do you personally know that statement to be a fact or theory, of your own knowledge?

A. I have a right to assume it as a fact.

2475 Q. You can answer it as many times as you want to, but you are going to answer that question if it takes all afternoon. *Do you know of your own knowledge* whether that statement is a fact or a theory?

A. That is from my own knowledge, from a careful study of conditions.

Q. Is it a fact or is it a theory?

A. I consider it a fact.

Q. Do you know that it is a fact?

A. I have a right to take it for a fact from the investigation.

MR. TODD: I move to strike out all his reasons that are not responsive to the question.

Q. Do you know that as a fact or a theory?

A. My experience justifies me in saying that I do know.

MR. TODD: I move to strike out the answer as not responsive.

Q. Do you know of your own knowledge?

A. As I said, I do know.

Q. That it is a fact or a theory?

A. As I said I do know that it is a fact.

Q. What are the places along the Missouri River at Kansas City or Council Bluffs, that you have personally investigated to accertain that fact?

2476 A. The analytical data would suffice.

Q. I didn't ask you about the data. I asked you about the place, the locality.

A. I have obtained it from the analytical data from those points.

Q. Were you ever on the ground, doctor?

A. Yes sir.

Q. Did you see the sewage of the city?

A. At what points do you ask me, where from?

Q. Have you seen the sewage of Omaha and Council Bluffs when it entered the Missouri?

A. No sir.

Q. Then can you state at that point that it is a fact or a theory?

A. At that point I could state it is a theory.

Q. At Kansas City, have you witnessed the sewage as it empties in the Missouri River?

A. I have been in Kansas City and investigated the conditions there, but I haven't seen the sewers myself, no sir.

Q. Well, then is it a fact or a theory as pertaining to Kansas City?

A. It is a theory justifiable from analytical data obtained.

MR. TODD: I move to strike out the latter part of the 2477 answer as not responsive.

MR. JEFFRIES: The witness has a right to explain when he answers in a passing way.

MR. TODD: I don't deny his right to explain. I simply want to reserve my rights in the record.

Q. As to Kansas City, have you any personal knowledge based upon observation as to how the sewage enters the Missouri River?

A. No sir.

Q. Now don't you see by answering "No" how easy we get along. As to Leavenworth, Kansas and St. Joseph, have you any personal knowledge as to how the sewage enters the Missouri?

A. No sir.

Q. Now what place along the Missouri River have you any personal knowledge as to how the sewage enters the river?

A. I haven't seen those sewer outlets with my own eyes.

Q. Then the statement that you made in regard to how the sewage enters the river and remains along the banks instead of entering the channel is a theory and not a fact personally known to you?

A. If you define it as personally known to me, I say that it is a theory.

2478 Q. Now if the theory, instead of being that the sewage was along the bank, should be a theory that the sewage enters the channel, how long would it take that sewage to become purified?

A. That again would be difficult to answer because it would depend upon the various conditions and the various circumstances that would have to be taken into consideration.

Q. What conditions and what circumstances would you take into consideration in order to answer that question scientifically?

A. First of all, the character of the sewage, the character of the manufacturing refuse going into the sewage—

Q. What do you mean by the character of the sewage?

A. The character, because the sewage may vary very much.

Q.. What do you mean by the character of the sewage?

A. Well I mean different characters. There are all kinds of material in the sewage, that justify and lead to the distinction of sewage of various kinds.

Q. What are the different kinds of sewage?

A. There is the sewage of fecal discharges; there is the sewage from the manufacturing establishments, from factories and slaughterhouses, from gas works, which is all discharged in that way and embodied in sewage. There are the washings from the kitchen, there is the dirt and dust in the street
2479 that is swept into the sewers by street sprinkling, or heavy
rainfalls, etc., that will give a varying character to the sewage constantly.

Q. Well, the character of sewage such as you find would obtain at Kansas City, Missouri, wouldn't it?

A. Well, I presume that the conditions would differ somewhat there.

Q. In what respects?

A. Well, because they are different cities.

Q. The fecal discharge would be the same, wouldn't it?

A. Well, I don't think it would.

Q. In what way would it differ from other cities?

A. Because much or a considerable percentage of the sewage of Kansas City don't go into the sewers at all.

Q. How about Omaha?

A. At Omaha again it depends upon how much sewage goes into the sewers.

Q. Well whether it is much or little, it has the same characteristics, hasn't it?

A. Well, it may if the same conditions prevail in both cities.

Q. What do you mean by the same conditions, doctor?

A. Well, one city may have a great many more slaughter houses, a great many more manufacturing establishments

2480 of one kind than the other. One city may have thousands of cess-pools and the other city may not, where the sewage is detained.

Q. But that relates to quantity, not to quality, doesn't it?

A. Well, but the quantity has a great deal to do with the effect that the sewage pollution will have on the water of the river.

Q. Well, assume that the quantity of one city is of a given amount, take Omaha and Council Bluffs, and that sewage is poured into the channel. How long would it take that sewage to purify itself in the channel?

A. That is very difficult to say.

Q. Have you any opinion upon it based upon scientific data?

A. Not as regards the city of Omaha.

Q. Have you any opinion in regard to Kansas City based upon scientific data?

A. No sir.

Q. Have you in regard to St. Joseph or Leavenworth, based upon scientific data?

A. No sir.

Q. Have you any opinion in regard to any of the cities located upon the Missouri River based upon scientific information?

2481 A. Well, what kind of information?

Q. As to how long it will require sewage to be purified that is emptied into the channel?

A. No, sir.

Q. And can you give any reason why this sewage becomes purified and the water rendered potable when it gets to Bellefontaine?

A. Yes, I have a reason why the water at the point of Bellefontaine is potable, based upon investigations I made of the Missouri River.

Q. What are those reasons, doctor?

MR. JEFFRIES: I object to the question because it is a repetition.

A. The great length of the river, its many curves and bends, its many sedimentation beds along its course, and the long time water takes to flow all this distance from Kansas City.

Q. What length of time, doctor?

A. According to the volume of water and the stages of the river.

Q. Give us some approximate idea in days?

A. There would have to be made a distinction between the velocity of the channel of the river, near the channel, and the velocity along the shores where the water frequently is
2482 impeded by flowing over the banks, and it almost stagnates, and that water requires flood water from the upper valley to flush it out and send it down the river.

Q. What is the distance from Omaha and Council Bluffs to Kansas City?

A. From Omaha and Council Bluffs by river?

Q. In going from Council Bluffs to Kansas City?

A. I have the data right here, I can tell you in a moment.

Q. I would like to have that in the record.

A. The distance from St. Louis to Omaha by the water line of the Missouri River is 676 miles; from St. Louis to Omaha.

Q. How much to Kansas City doctor?

A. From St. Louis to Kansas City it is 403 miles.

Q. How far is it from Omaha to Kansas City?

A. The distance from St. Louis to Omaha being 676 miles, and the distance from St. Louis to Kansas City being 403 miles, would make the distance 273 miles between Omaha and Kansas City.

Q. What is the character of the sewage, doctor, that empties into the Missouri River at Kansas City?

A. The character of the sewage entering the Missouri River at Kansas City is that of the city, a sewage very high in percentage of refuse matter from slaughterhouses and rendering establishments, and it contains 60 per cent. of the
2483 sewage of Kansas City as discharged into the river. This sewage of course includes the fecal matter—it includes

all the dirt in the streets as swept into the sewers from rainfall or from street sprinkling.

Q. How about the slaughterhouses, doctor?

A. I say that the high percentage comes from the slaughterhouses.

Q. How many slaughterhouses are there in Kansas City?

A. That I don't know. There are a very large number.

Q. It is a vast amount of sewage, isn't it, that enters the river at Kansas City from slaughterhouses and other manufactories?

A. There is considerable sewage entering from that source, yes, sir.

Q. What is the character of that sewage as to bacteria?

A. That I am not prepared to state. I could not say so.

Q. Is the refuse of the slaughterhouses more pregnant with bacteria than the fecal discharge?

A. From a general standpoint, I think not.

Q. Does that sewage from Kansas City purify itself in the Missouri in going 400 miles?

MR. JEFFRIES: I object to the question because it is immaterial and irrelevant.

2484 A. The chemical analyses of samples of water taken at Fort Bellefontaine show that whatever water pollution—

Q. Can you answer that, yes or no, doctor?

A. I am answering it, but it requires an explanation.

Q. Answer it first and explain afterwards?

Q. (Question repeated.)

A. Whenever sewage pollution has taken place from the sewage of Kansas City, that sewage pollution has to such an extent disappeared that when the water reaches Fort Bellefontaine, after a run of 403 miles, that water is potable at Fort Bellefontaine.

Q. What is the velocity of the waters of the Missouri, the main velocity between Kansas City and St. Louis?

A. Well, I couldn't tell you what the amount of the velocity is; I haven't got the data with me.

Q. Is the current in the Missouri River swifter than the current in the Illinois?

A. That depends upon the river stage, the volume of water.

Q. Well, at a normal stage?

MR. JEFFRIES: I object because it is immaterial.

THE WITNESS: At a normal stage the water in the channel?

Q. MR. TODD: I mean the normal stage in the Missouri and the normal stage in the Illinois.

A. Well, it is my opinion that it is slightly swifter.

2485 Q. In what?

A. And on such occasions when the Missouri River is high, but when the Missouri River is low of course the current is sluggish and slow.

Q. But when the Missouri River is low and the Illinois River is low, how do the velocities of those two streams compare?

A. I think they would be about alike.

Q. Isn't it a fact, doctor, that the velocity of the current of the Missouri River is much swifter than that of the Illinois?

A. Well, at low stages I should think they would be more alike.

Q. I mean at similar stages?

A., At similar stages I think that the Missouri River is for a larger time higher, and that the velocity exceeds as I said already, that of the Illinois River, of the channel always of the channel, not the shore water.

Q. I am speaking of the channel of the Illinois and Missouri. How swift is the current in the channel of the Missouri River?

A. Do you mean the average?

Q. Yes, the average?

A. The average would be three miles, from three to
2486 three and one-half miles.

Q. Per hour?

A. Yes, sir.

Q. What is the average current in the Illinois River?

A. Well, that depends very much upon the back water at the mouth of the Illinois.

Q. Well, under normal conditions, under similar conditions with the Missouri?

A. There are times when the upper Mississippi River is very high, and the volume of water coming down is so large that the velocity of the current in the Illinois River for more than 50 miles upward is greatly impeded, so that it is almost difficult to form an average there.

Q. For how long a period does that exist?

A. It may be.two miles and it may be more.

Q. I mean in time; how much time during the year does that condition exist in the Illinois?

A. Well—

Q. Approximately, six months in the year?

A. I couldn't tell you.

Q. Three months?

A. I haven't made any measurements of the Illinois River.

Q. Well, what is the velocity of the current of the Illinois
2487 River?

A. Well, I have been at times on the Illinois River, when the current was one mile; and then again when it was declared to be two miles an hour, but not from my own measurements or investigation.

Q. Do you know of it ever being over two miles an hour?

MR. JEFFRIES: I object, because the witness has already said he didn't know.

A. I think so.

Q. MR. TODD: How much faster than two miles an hour have you known the current to be?

A. Well, at times, at high water, I have known that it was three miles an hour.

Q. In times of high water in the Missouri how fast is the current?

A. The current can go up at high water, to three and a half miles and possibly four miles.

Q. Four miles an hour?

A. Yes, sir.

Q. When the current in the Missouri is four miles an hour and the sewage of Kansas City entering into the Missouri river, will that sewage purify itself before it reaches St. Louis?

MR. JEFFRIES: I object to the question because it is immaterial and doesn't tend to prove any issue in the case

2488 and because it assumes a fact which has not been proven in the evidence.

A. It is hard to tell; it depends entirely upon the conditions.

Q. Will the sewage from slaughterhouses purify itself in running streams, purify itself in four days, doctor?

A. That is a question that would require a test to be made and investigations would have to be made to establish that.

Q. Have you made tests sufficient to answer that question?

A. No, sir.

Q. Then how can you state that the waters of the Missouri River all the time are potable, in view of the fact that when the current of the river is four miles an hour, and it is only 403 miles from Kansas City to St. Louis, which at that rate would be four days for the sewage to get from Kansas City to St. Louis that the water is potable?

A. I can only form the conclusion that the water is potable, from the chemical analyses performed upon the water taken from the Missouri River at Fort Bellefontaine, and the water was potable.

Q. Have you ever analyzed waters taken from the river at Bellefontaine when the current of the river was four miles an hour?

2489 A. Yes, sir; very likely.

Q. Have you?

A. Well, I have the data to find out on which days when samples were taken, such was the case, but I haven't got it at hand just now. I could ascertain that fact. Very likely that did occur because we analyzed samples taken from Fort Bellefontaine daily from January until October, 1900.

Q. Then, if your analytical data is correct, does it not justify the conclusion that the sewage would purify itself in running waters in four days?

A. Not as such.

Q. Why, doctor?

A. Because it all depends upon the varying conditions and the circumstances prevailing along the route of such river which must be considered in determining the question whether or not sewage running such a distance will purify itself.

Q. If your analytical data is correct, wouldn't it justify the conclusion that when the current of the river is four miles an hour that it will purify itself in running a distance of 403 miles?

A. My data wouldn't enable such a conclusion.

Q. Would your data enable you to draw any conclusion as to how long or how far it would require in order to purify its original stream?

2490 A. No, sir.

Q. It might be a less time than four days that the sewage would purify itself in running waters, might it not?

A. Not usually with the conditions as they prevail in the various rivers.

Q. In the Missouri River I am speaking about now?

A. I cannot draw the conclusion that sewage will purify itself in four days running.

Q. Why, doctor?

A. Because it cannot be ascertained whether it came down in four days.

Q. How long would it take water to come from Kansas City to St. Louis, running at the rate of four miles an hour?

A. I can only make an estimate of the current in the channel.

Q. Well, in the current?

A. The regular channel, how long it would take channel water to come down at that rate?

Q. That's what I mean?

A. Well, four days as you say.

Q. Now, if this sewage should get into the channel, is there any reason or any law known to you which would preclude that sewage from coming along with the rest of the channel water down the river to St. Louis?

A. If the quantity of sewage was very large when it
2491 would get into the channel, and the current very swift,
the chances are it would be carried a very long distance before having undergone sufficient oxidizing processes to call it potable.

Q. What quantity of sewage would you think would be necessary to carry it 400 miles in the channel?

A. Well, the sewage itself in being carried that far, if it is in the channel entirely, it will take much longer to purify it.

Q. Does the quantity of sewage in the channel have anything to do with its purification?

A. Yes, very much so.

Q. In what way, doctor?

A. Because the more sewage you discharge into the channel the more will that sewage prevail in the channel and the natural processes of purification will be so much slower. There is so much more material to decompose, to disintegrate, to disorganize, and to render soluble, and to prepare in the proper form and in the proper condition for the aerobic bacteria to finish the processes of purification.

Q. Well, now, if the sewage goes into the channel at Kansas City, in any large quantities from the slaughterhouses there, wouldn't it be completely destroyed by the time that it got to St. Louis, if it only took four days for it to go?

2492 A. It would depend very much upon the quantity of the sewage that would go into the river. It would depend upon the weather conditions, whether it was warm weather, that would facilitate the processes of oxidation, etc., and there would be a great many circumstances that would go into consideration to determine whether that sewage after running four days at four miles an hour would purify itself. It would depend very much upon the various circumstances.

MR. JEFFRIES: I move to strike out all the testimony in reference to the water in the Missouri River, which has been introduced for the reason that it is immaterial and has no bearing upon the issues in the case, and I move to strike it out for all purposes except as to the effect it might have upon the competency of the witness.

MR. TODD: What character of sewage will purify itself most rapidly, slaughterhouse sewage, that is the refuse from slaughterhouses, or what is known as household sewage?

A. Household sewage varies.

Q. I mean—

A. If you mean fecal matter—

Q. Yes, fecal matter.

A. You mean fecal matter?

Q. Yes, and the urine?

2493 A. The slaughterhouses refuse is more apt to deposit itself and disappear in the sludge at the bottom of the river. The fecal matter, however, is more apt to remain in the floating part of the water, and then the fecal matter, I mean principally the fecal matter in solution, that is the urine, which forms a very large component part of this matter; that of course being in solution would show a different character than the refuse from slaughterhouses.

Q. Now, doctor, returning to the original question, which one will purify or oxidize more quickly, that from the slaughterhouse or from the household, including fecal discharge?

A. That is difficult to determine, which will purify itself quicker.

Q. Which would oxidize and disappear?

A. I couldn't tell you.

Q. Haven't you, as a chemist, given that question any consideration?

A. I have endeavored to obtain all the information I could possibly get on that subject.

Q. I am not asking you what other people have told you. I cannot cross-examine those other gentlemen you are talking about. I have got to address myself to you, doctor?

A. Yes, sir.

Q. Have you, Dr. Teichmann, investigated that phase 2494 of the question so as to be able to give a scientific answer?

A. I haven't made any special researches to determine whether the fecal matter or slaughter sewage will be decomposed more rapidly.

Q. What are the principal constituents of slaughterhouse sewage?

MR. JEFFRIES: If you know?

A. Well, such refuse—

MR. TODD: Well, do you know, doctor?

A. Yes, sir.

Q. What are they?

A. Such refuse as are usually thrown away.

Q. Well, chemically speaking?

A. Well, organic matter.

Q. What kind of matter?

A. Organic matter of animal origin.

Q. Well, how are they chemically spoken of, doctor?

A. Well, they are compounds, composed of carbon, nitrogen, hydrogen and oxygen.

Q. Well, aren't all elements nearly composed of carbon, oxygen, hydrogen and nitrogen?

A. Those are the elements, yes, sir.

Q. Isn't nearly everything in nature composed of one or more of those elements?

A. They are very abundant in nature.

2495 Q. I was taught that in chemistry?

A. Yes, they are very abundant in nature.

Q. Now, is that the best answer that you can give to my question as a scientific man, that the chemical characteristics of the sewage of slaughterhouses are composed of hydrogen, nitrogen, oxygen and carbon?

A. Compounds principally.

Q. What compounds?

A. Well, what we call organic compounds.

Q. Well, the organic compounds are divided into what?

A. Into innumerable classes.

Q. Name them—you needn't scare us now, we can stand a little more of it. Just give me the names.

A. Well, say albuminous compounds.

Q. What other compounds?

A. Well, various others.

Q. Well, can you name them?

A. Then other elements would come into consideration.

Q. Let us stick to the compounds, doctor, just name them.

A. I think albuminous compounds cover them principally.

Q. Is that the best answer you can give to the question?

A. Yes, sir.

Q. What are the chief things in household sewage?

2496 A. Now, do you mean simply the washings from the sinks?

Q. The chemical constituents?

A. Or do you mean the fecal matter?

Q. Everything—all?

A. Well, various compounds of organic character.

Q. What are they, doctor? Just name them?

A. Well, the urine—

Q. Well, let us take the urine, what are the chemical compounds of the urine?

A. There are a great many compounds represented in urine.

Q. Well, what are they?

A. Well, sodium chloride is one.

Q. Well, what are the others?

A. There are several others.

Q. Just name them?

A. Uric acid, urea.

Q. What others?

A. There are several other organic compounds.

Q. Can you recall them now?

A. You might include some other salts that appear in the urine sometimes.

Q. Is that all that you can name?

A. Well, I think it is sufficient.

Q. Well, what are in the feces?

2497 A. The feces are also composed of organic compounds principally.

Q. What are they?

A. Formed from the elements that I have already mentioned, carbon, nitrogen, hydrogen and oxygen, together with other compounds represented and coming from other elements.

Q. To be specific, what chemical elements or compounds are in the feces different from those four compounds of nitrogen, hydrogen, oxygen and carbon?

THE WITNESS: Now, Mr. Todd, I have anwsered a great many of these questions and I have passed an examination on the elementary principles of chemistry, when I graduated from the university. As I testified, I have been an instructor of chemistry in a medical college of St. Louis. I am supposed to know a great many things that are necesary for any man, a chemist, to pass an examinaton, and to furthermore act as an instructor. I think that after having answered questions like that officially, that I am entitled to the privilege of refusing to answer further questions that I have answered a long time ago when I qualified myself as a chemist.

Q. Doctor, in the question that I asked you that you object to answering, all you have to say is, "I decline to answer." And there will be no argument between us. You understand I
2498 mean no discourtesy by the questions that I ask you. I
have in view questions that I want to ask you. I ask you these questions for the purpose of basing the other questions which I have in view to ask you.

THE WITNESS: I understand your motive as not at all being personal; but when I am asked questions, "What are the chemical constituents of urine," and I answer that question, and it goes on, "What are the chemical constituents of feces and such things," it is practically interrogating me on knowledge that every chemist ought to possess. It is fundamental knowledge. I think I will have to be excused from answering that question. I have given my reasons.

Q. Mr. TODD: The Supreme Court takes no judicial notice of chemistry or the chemical constituents of feces, except as testified to under oath by a competent chemist, and I want to get this in the record.

Q. Is it not a fact that the most important element that enters into this investigation is the feces and urine of animal or man?

MR. JEFFRIES: I object because it is an argument with the witness. You can ask him all the questions you please, but when you ask him as to his judgment upon this litigation, it is arguing the question with him.

2499 Q. MR. TODD: Is it not a fact that in the contamination of streams the most important elements entering into the question of pollution are the elements which are known as feces, or urine of man or animal?

A. I have answered that question, in so far as stating what the number of elements are that form the compounds that causes that.

Q. You don't get my question.

A. What is called the formation of feces. That ought to be sufficient.

MR. TODD: I object to the witness passing upon the competency of my question.

Q. (Question repeated.)

A. Yes, I have answered that question.

Q. Now, what are the chief compounds in feces? Answer that?

A. Now, I will answer that in one general answer—carbonaceous and nitrogenous compounds.

Q. Are those general compounds divided into individual compounds?

A. They are represented by a number of organic compounds, yes.

Q. What are those compuonds?

A. The chief compounds are carbonaceous and nitrogenous compounds.

2500 Q. I mean, doctor, have they any other name?

A. Of various kinds. It shouldn't be necessary to answer a question in detail as if—

Q. What are the names of those compounds?

A. Now, as I said before, when I answered the previous question—

MR. JEFFRIES: Go ahead and answer that question.

A. I refuse to answer that question.

THE COMMISSIONER: Doctor, the Commissioner cannot compel you to answer, but there are processes by which you could be compelled to answer. It is a fair question. It will be better for you to answer it.

A. I have already answered that question intelligently, and that ought to be sufficient.

MR. TODD: Do you want to pass upon the questions that are asked you as to whether you will answer them or not, doctor?

MR. JEFFRIES: That is an objectionable question, and I will permit him to answer without objection.

A. I will refuse to answer the question, as I said before.

MR. TODD: Do you refuse to answer any further questions in regard to the component elements or chemical elements of feces?

A. No, when they are embodied in general terms sufficient to answer questions, I shall not refuse.

2501 Q. Do you refuse to answer the questions that pertain particularly to the component elements?

A. I have mentioned the component elements represented by the compounds classed in the way I have mentioned.

Q. (Queston repeated.) Is that the only answer you will give to that quetsion, doctor?

A. Yes, sir.

Q. And you refuse to go into further details?

A. No, not exactly; it depends upon the nature of the question.

Q. The question is to name the important compounds in feces?

MR. JEFFRIES: As many as you can.

A. I named those.

Q. MR. TODD: And is the answer that you made, the only answer that can be made by a chemist to that question?

A. I consider that answer a sufficient reply to the query made.

Q. Have these compounds any names different from the names you have given?

A. Certainly.

Q. What are they?

MR. JEFFRIES: Name them.

A. No, I won't name them; I refuse.

Q. MR. TODD: You refuse to answer that question, do you?

2502 A. Because I have answered that question already.

Q. Is that the best answer you will give to that question and the only one?

A. Yes, sir.

Q. Doctor, from the known composition of slaughterhouse sewage and household sewage, which in your opinion will oxidize, or purify itself more rapidly?

A. It is difficult to determine.

Q. Have you any opinion upon the question?

A. No, sir.

Q. In your examination at Fort Bellefontaine, did you find albuminoid ammonia in the waters of the Missouri River?

A. Yes, sir.

Q. Was it high or low?

A. It varied considerably according to the data received.

Q. What was it mostly, high or low?

A. The albuminoid ammonia in comparison with the free ammonia was considerably high.

Q. What does that indicate, doctor?

A. That indicates contamination of organic matter.

Q. Does it indicate anything else?

A. That could only be determined by taking into consideration other chemical ingredients found in the water.

Q. Does it indicate anything of itself?

2503 A. That depends upon whether the albuminoid ammonia was found in suspension or solution.

Q. If in suspension, there was more than in solution, what does that indicate of itself?

A. If there was more in suspension than there was in solution, it would indicate organic matter due to the contamination of vegetable origin.

Q. Why not animal origin, doctor?

A. Because the organic contamination of animal origin is more represented in the albuminoid ammonia in solution.

Q. Why?

A. Because the organic matter of animal origin that is found in solution in the albuminoid ammonia will represent to a large extent the pollution of animal origin in soluble forms.

Q. If the albuminoid ammonia is in solution instead ot suspension to a high degree, what would that indicate?

A. Well, that will enable the conclusion that the origin ot the organic matter may be more from animal sources.

Q. In what condition would you find the albuminoid ammonia from the sewage of slaughterhouses, in suspension or solution?

A. Well in both, very likely.

Q. Which would prevail the more largely?

A. In suspension.

2504 Q. In what condition did you find the albuminoid ammonia in the Mississippi River at Bellefontaine?

A. You mean in the Missouri River?

Q. Yes, I mean in the Missouri River?

A. I found considerable high albuminoid ammonia.

Q. Was it in suspension or in solution?

A. Partly in suspension and partly in solution.

Q. Which more?

A. At times the albuminoid ammonia in suspension would be larger than the albuminoid ammonia in solution, and at other times the reverse would show.

Q. If that is true, how would you distinguish between the albuminoid ammonia of vegetable and animal origin?

A. The distinction could be made from that point of view, that the organic matter in suspension is very largely composed of such matter as is of vegetable origin.

WILLIAM C. TEICHMANN.

Adjourned until ten a. m., Wednesday, April 1, 1903.

2505 Southern Hotel, St. Louis, Missouri, 10:00 a.. m., Wednesday, April 1st, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN, resumed the stand for further cross-examination, by Mr. Todd, and testified as follows:

Q. Doctor, is the albuminoid ammonia found at Bellefontaine, Missouri, in solution or suspension?

A. It varies. For a larger part of the time the albuminoid ammonia in the water from that point appears to be in suspension and the smaller part in solution, but there are times when the albuminoid ammonia in suspension is less than the albuminoid ammonia in solution.

Q. What is albuminoid ammonia, doctor?

A. Now Mr. Todd, I would like to make a statement regarding—

Q. Just answer my question, doctor, and at the conclusion you may make any statement you desire.

A. I beg your pardon; what is the question?

Q. What is albuminoid ammonia?

2506 A. Albuminoid ammonia is the product of a distillation process with a chemical called potassium permanganate; it is the ammonia that is received as the distillate from the distillation of the sample of water with this chemical—potassium permanganate.

Q. What is the origin of albuminoid ammonia?

A. Organic matter.

Q. Is that organic matter from animal or vegetable origin?

A. It may be from animal and it may be from vegetable origin.

Q. When albuminoid ammonia is found in water, whether in suspension or in solution, is there any marked characteristic of the albuminoid ammonia so found that enables a chemist to determine whether it is from vegetable or from animal origin?

A. A number of responsible chemists endeavord—

Q. Well, just give me your opinion, doctor. I don't want the chemists; I can't cross-examine them.

A. Well, it is the custom to make a distinction there in the manner in which the ammonia distills over in the distillation apparatus, and in the amount of what we call oxygen consumed found, that is, organic matter estimated by the so-called Kugel oxygen consumed process.

Q. I will put the question in another way, doctor. Is albuminoid ammonia which is derived from animal origin
2507 identical with the albuminoid ammonia which is derived
from vegetable origin?

A. Well, since what we call albuminoid ammonia is a product of distillation, the distillate itself would not enable a distinction unless other points are considered in determining whether it may be of vegetable or animal origin.

Q. Then albuminoid ammonia derived from vegetable is the same ammonia that is derived from animal?

A. Well, as a product of the distillation it is the same.

Q. There are no identifying characteristics of albuminoid ammonia when it is found, that will enable the chemist to say whether that ammonia came from vegetable or animal origin, is there?

A. Not if he bases his opinion solely on the product of distillation.

Q. I am talking about albuminoid ammonia, now as such.

A. Yes sir.

Q. Distinct from everything else.

A. Now, Mr. Todd, I would like to make a statement regarding my refusal yesterday to answer a question—

MR. TODD: I submit that the proper time for that is on rebuttal.

THE WITNESS: (Continuing) I was under a mental strain at that time and had become very nervous owing to

2508 two days cross-examination and somewhat irritated, and therefore refused to answer a question. I realize that the question was justifiable since it was connected with fundamental principles involved in this investigation and litigation, so that I wish to say that I have reconsidered my refusal and am willing to answer that question as it is my duty to do so.

Q. Now, doctor, when you find albuminoid ammonia in water, the albuminoid ammonia may be attributable to vegetable or animal matter origin?

A. Yes sir.

Q. And is there anything in the albuminoid ammonia itself that will enable the chemist to ascertain whether it came from animal or vegetable origin?

A. No sir, not in the analytical product, itself.

Q. In the Missouri River you found albuminoid ammonia in solution and in suspension?

A. Yes sir.

Q. In different degrees?

A. Yes sir.

Q. When albuminoid ammonia is found in suspension, does that indicate whether it is of animal or vegetable origin?

A. Well, that could not be determined from the analytical product itself.

2509 Q. If albuminoid ammonia was in solution, would that indicate whether it was from vegetable or animal origin?

A. Not if determined as found from the analytical product itself.

Q. When you find albuminoid ammonia in solution and in suspension, does that indicate whether the albuminoid ammonia is from animal or vegetable origin?

A. Not if viewed from the analytical product itself.

Q. In the process of purification albuminoid ammonia, whether in suspension or solution, changes to free ammonia does it not?

A. Well, what we call free ammonia there, is also the analytical product received from the distillation process, without the addition of the permanganate solution; when we add permanganate solution to the water and distill it, then we get albuminoid ammonia, so they just classify two kinds of ammonia,—we call the first free ammonia, but it is not free ammonia as such.

Q. Well, albuminoid ammonia is nothing more than albuminoid substances found in the water, is it not?

A. Well, it is supposed to represent what is in the water as organic matter either of vegetable or animal origin.

Q. Known as albumen?

A. Yes sir.

Q. Or related to it?

2510 A. Yes sir.

Q. Then when this albumen which we denominate albuminoid ammonia becomes disintegrated by bacteria, or oxidation, it gives what is known as free ammonia, does it not?

A. Yes—well, carbonate of ammonia, by the action of the bacteria in the water, carbonate or chloride of ammonia is supposed to be formed there.

Q. But the basis of the free ammonia is the albuminoid ammonia or the albumen in the water?

A. Yes sir.

Q. Then when the free ammonia by similar process of oxidation or bacteria, is broken up, it results in what is known as nitrites?

A. Yes sir.

Q. And the nitrites by a similar process, change into what is known as nitrates?

A. The final product of the cycle of nitrification.

Q. Nitrates?

A. Yes sir.

Q. So that in the beginning is what is known as albuminoid ammonia or albumen in the process of fermentation or purification?

A. Yes, probably carbonate of ammonia and chloride of ammonia, but including of course these albuminous compounds.

2511 Q. Now albuminoid ammonia is present in the sewage from slaughter-houses and fecal discharges from man and animal, is it not?

A. Yes sir.

Q. It is also found in the decomposition of vegetable matter?

A. Yes sir.

Q. It manifests itself—pollution from vegetable or animal matter manifests itself in water in what is known as albuminoid ammonia?

A. That is—well it manifests itself in the analysis of the water as albuminoid ammonia, yes sir, representing that organic matter.

Q. Albuminoid ammonia evidences the presence of vegetable or animal pollution?

A. Yes sir.

Q. Albuminoid ammonia appears in suspension or in solution in waters does it not?

A. Yes sir.

Q. When it appears in suspension what does that indicate, vegetable or animal origin?

A. Well since most of the albuminoid ammonia of animal origin is generally supposed to be contained in solution the conclusion is drawn that much of the vegetable organic
2512 matter in the waters being insoluble, this latter would be represented in the suspended matter, and the general conclusion is that in suspended matter, when there is high suspended matter present, that this suspended matter is largely of a vegetable character, but not altogether. There may also be a solid matter of animal origin in that water and found in suspension.

Q. Doctor, as a chemist, do you enunciate that as a principle, of chemistry, which you yourself, by your analytical investigations have established,—that albuminoid ammonias in suspension indicate vegetable origin and albuminoid ammonias in solution indicate animal origin?

A. I said that they may be present in both; not altogether, in one.

Q. If they are present in each class, suspension or solution, how are you able to differentiate between albuminoid ammonia which is of vegetable origin and the albuminoid ammonia which is of animal origin?

A. Because I take into consideration the oxygen consumed results, the oxygen consumed results enable in a measure an opinion as to the vegetable or animal origin, or whether the vegetable or animal matter prevails in that albuminoid ammonia.

Q. Doctor, is chemistry an exact science

A. It is supposed to ascertain facts only, and therefore is an exact science.

2513 Q. It is generally accepted among scholars as an exact science, is it not?

A. Yes sir.

Q. Almost on a par with mathematics, in its exactness?

A. Yes sir.

Q. Is there anything in chemistry and has there been an established principle that albuminoid ammonia when found in suspension or in solution in running waters, that it can be accurately and definitely ascertained whether that albuminoid ammonia originates from animal or vegetable origin?

A. Some of the greatest authorities are willing to draw conclusions by comparing the albuminoid ammonia results analytically, and the oxygen consumed results analytically, are willing to form conclusions—general conclusions, as to the prevailing character of that albuminoid ammonia, whether it is of animal or vegetable origin. Such authorities as Leffman, for instance, Leffman and Beam, and Professor Drown, in a measure, lay a certain stress on this distinction to be made in judging whether it is of vegetable or animal origin.

Q. Does he hold that albuminoid ammonia of vegetable origin is found in suspension rather than in solution?

A. Leffman and Beam hold that when certain observations are made as to the way in which the ammonia distills over from the original flask in which the water is contained,
2514 into the tubes, that when this ammonia organic matter
comes over—I mean organic matter is found to be high, according to the oxygen consumed process of the Kulel method by which organic matter is determined, that would indicate vegetable origin. If the organic matter however, as ascertained by oxygen consumed power, is low, with the high albuminoid ammonia, he ventures to say that it indicates animal origin.

Q. By indicating, do you mean demonstrating?

A. Yes, I construe that—

Q. Is it a chemical demonstration?

A. Yes sir, according to his own statement in his book on "Examination of Waters."

Q. Do you as a chemist enunciate the principle that albuminoid ammonia in suspension demonstrates the vegetable origin of the albuminoid ammonia?

A. Not if viewed from the analytical product of the albuminoid ammonia in the distillation process itself. Only by comparing the results with those obtained from the oxygen consumed test as Professor Leffman advises in his book, in which he draws these conclusions.

Q. (Question repeated)?

A. As I said, not if viewed from the sole analytical product of albuminoid ammonia as received by distillation.
2515 Only, I said, could we look for vegetable origin in the oxygen consumed power as obtained by the so-called Kulel oxygen consumed process by comparing the results, could we look for vegetable origin there, if the results justified it.

Q. Then albuminoid ammonia in suspension does not demonstrate whether it is of vegetable or animal origin in itself, does it?

A. Not if you take the albuminoid ammonia analytically, the result by itself.

Q. By itself?

A. You could not tell, no sir.

Q. And does the albuminoid ammonia in solution demonstrate its animal or vegetable origin?

A. In a measure only, if the general analytical result and the oxygen consumed results are taken into consideration. It is by comparing the general analytical results, estimation of other characteristic ingredients of sewage, that one would be justified in drawing a definite conclusion.

Q. Are not the vegetable substances mostly in solution?

A. Well, that cannot be determined. There are vegetable matters in solution and vegetable matters in suspension; vegetable matters that are indissoluble in water, that will remain in this suspended matter accordingly; whereas, there are
2516 other vegetable matters that may by chemical process be partly converted into soluble compounds which would be represented in the ammonia in solution.

Q. What are the substances of vegetable origin which yield albuminoid ammonia?

A. Well, there are multitudes—plants, leaves from the trees, wood. The plants that are connected with the soil that is washed into the rivers.

Q. The chemical compounds, doctor, I mean, what are the chemical compounds?

A. The chemical compounds, well, that depends upon the vegetable matter itself. There may be a great many of them. For instance the different vegetable plants, different vegetable growths will all have different chemical constituents.

Q. Does albuminoid ammonia from animal origin appear in solution and in suspension in water?

A. Yes, it may.

Q. Does albuminoid ammonia from vegetable origin appear in suspension and in solution in water?

A. Yes sir.

Q. Now will you tell me how you can ascertain and differentiate the origin of albuminoid ammonia as to whether it is vegetable or animal origin when found in water in suspension or solution?

2517 A. As I said, professor Leffman—

Q. I would prefer doctor, to have Professor Teichman. I can't cross-examine Professor Leffman.

A. Well, I take the result of the distillation for albuminoid ammonia and I watch the distillation process in itself to notice whether the ammonia comes over rapidly or whether it comes over slowly. I then take the oxygen consumed results and see whether they are high or low as compared with the albuminoid ammonia results. If the albuminoid ammonia found is low—well, that in itself would show low albuminoid ammonias. If the albuminoid ammonia is high, and the oyygen consumed is low, that would indicate in accordance with the opinions of authorities that the conclusion is justified that the albuminoid ammonia is prevailingly—not altogether—but prevailingly of ammonia origin.

Q. Have you ever analyzed the waters of swamps?

A. Yes sir.

Q. Is the albuminoid ammonia high or low in the waters of swamps?

A. The albuminoid ammonia may be high.

Q. And if the albuminoid ammonia is high, what does it indicate?

A. It indicates pollution by organic matter.

2518 Q. Of vegetable or animal origin?

A. If the result of the analysis of that same water for oxygen consumed is taken into consideration and also the result obtained for nitrites and chlorines—if all the other results show low figures, and only the albuminoid ammonia figure shows high, the albuminoid ammonia can in such a case be ascribed to vegetable origin. Professor Drown, one of the leading authorities, enunciates that opinion in his famous report to the State Board of Health of Massachussets.

Q. Can you tell from the presence of nitrites whether the nitrites come from vegetable or animal origin?

A. I would only take the general results of the entire analysis and certain local conditions as they are prevailing at the point where the sample is taken. After considering all these circumstances, the nitrites would form part of the basis from which the conclusion may be drawn that this water may be of sewage origin.

Q. That is, if you knew independent of chemistry that the water was sewage contaminated from the sewage of man or animal, then the nitrites appearing there, you would draw the conclusion that they came from animal rather than vegetable origin, is that correct?

A. Yes sir.

2519 Q. If you didn't know the origin, but only had the nitrites to go upon, could you tell whether it was of vegetable or animal origin?

A. No sir, not if I took the nitrite results by themselves, I could not do it.

Q. It is impossible then to ascertain from nitrites per se, whether they come from vegetable or animal origin?

A. Yes sir, you are right there.

Q. In free ammonia, if you don't know the origin, is it possible to tell whether it comes from animal or vegetable origin?

A. That depends upon the general analytical results.

Q. Give me an example, doctor, wherein you can tell whether free ammonia comes from vegetable or from animal origin, in the absence of any knowledge outside of chemistry?

A. When the general analysis shows certain corresponding conditions, I will say high nitrites, and high chlorines—

Q. I am asking about free ammonia, doctor. I will get to that later.

A. (Continuing)—and high free ammonia, when those three go together, the general rule is to consider the pollution there of sewage origin. High nitrites, high chlorines, and high ammonias going together indicate sewage pollution.
2520 That is, it has been established as an axiom of sanitary science by the investigations conducted under Professor Down for the Massachusetts State Board of Health.

MR. TODD: I move to strike out the answer as not responsive, and ask to have the question read again.

MR. JEFFRIES: I think he gave you the example that you called for.

Q. (Question read).

MR. TODD: I withdraw my motion to strike out. I had another question in mind.

Q. Can you tell by the presence of free ammonia in itself, whether it is of animal or vegetable origin?

A. No sir.

Q. Can you tell of nitrites in itself, whether it is of vegetable or animal origin?

A. No sir.

Q. Can you tell of nitrates in itself, whether it comes from vegetable or animal origin?

A. No sir.

Q. Nitrates come from nitrites?

A. Yes sir.

Q. Nitrites from free ammonia?

A. Yes sir.

2521 Q. Free ammonia from albuminoid ammonia?

A. Well, yes, you may consider it that in your interpretation.

Q. Then in order to ascertain whether the nitrites, nitrates and free ammonias are of vegetable or animal origin, you must ascertain first as to whether or not the albuminoid ammonia is of vegetable or animal origin, mustn't you?

A. No sir, not if you take the nitrites and the chlorines and the free ammonias together, it is not necessary then to determine whether the albuminoid ammonia is of vegetable or animal origin.

Q. What does high chlorines in a river indicate, doctor?

A. High chlorines in a river by themselves, you mean?

Q. Yes.

A. They may indicate sewage pollution and they may indicate the passing of the river through a deposit of salt in the geological structure.

Q. So that it is uncertain, is it not, what it indicates?

A. Yes sir for chlorines alone.

Q. Chlorines alone?

A. Yes sir.

Q. Chlorine is the only element entering into water from sewage that does not change its form, is it not?

A. Well there are constantly chemical changes going on; 2522 salts are being formed in the rivers.

Q. I know, but chlorine does not ever loop into something else like nitrites into nitrates, does it?

A. No, not in that form, because the chlorine there is supposed to be present in the form of sodium chloride and that is a salt in itself, which is fixed.

Q. Fixed?

A. Yes sir.

Q. Now in Kansas City there is a great amount of sodium chloride going into the Missouri River, isn't there?

A. Yes sir.

Q. There is a great amount at Council Bluffs and Omaha, and Leavenworth, Kansas, and all the towns that empty their sewage into the Missouri River, this sodium chloride is coming into the river from the sewage, is it not?

A. Well, I would make a distinction there, between high chlorines coming from the Kaw River or the Kansas River—

Q. I understand that.

MR. WOERNER: Wait a minute. Just finish your sentence.

A. (Continuing) You see I distinguish there between the chlorines found in the Missouri River above Kansas City, and above the junction of the Kansas, or Kaw River with the Missouri and the chlorines below.

MR. TODD: I move to strike out the answer, and ask to
2523 have the original question read.

Q. My question, doctor, is this. Does the sewage from all the cities upon the Missouri River entering into the Missouri River carry with it sodium chlorides?

A. Yes sir.

Q. That is the point I make.

A. Yes, they do.

Q. And in addition to that you have testified about the Kaw River?

A. Yes sir.

Q. Can you as a chemist, distinguish the sodium chloride which comes from sewage from the sodium chloride which comes from the salt beds of the Kaw River as you have testified?

A. No sir, not chemically, no sir.

Q. Did you take into consideration in drawing your conclusions as to the conditions of the Missouri River, as to its potability, the sodium chloride which entered that river from the sewage of all the cities along it?

A. In a measure, yes.

Q. In what measure, doctor?

A. Well, there is a certain amount of chlorine found in the Missouri River above the mouth of the Kaw River, that is true the analyses show that, and also a certain amount of chlorine is found in the Missouri River after the Kaw River emp-
2524 ties into the Missouri River.

Q. And when it got to Bellefontaine, were you able to state what percentage of the chlorine which you there found, came from sewage, and what percentage came from the Kaw River?

A. No sir.

Q. Whether the percentage from the sewage was larger than the percentage that came from the Kaw, are you able to ascertain chemically?

A. No sir.

Q. So that the presence of chlorine which you discovered by your analyses in the waters at Bellefontaine, you cannot state whether the greater proportion came from sewage or not, can you?

A. The conclusion is justified there that since the chlorines are uniformly—the average chlorines uniformly higher between Kansas City and Bellefontaine, than they are between Omaha and Kansas City, the conclusion is justifiable that since as much as 100 parts per million or five and six times as much chlorine is found in the Kaw River, that the Kaw River certainly is responsible for the high chlorines prevailing between Kansas City and Bellefontaine as compared with the chlorines between Omaha and Kansas City.

Q. Where does the Kaw River enter the Missouri River, 2525 above or below Kansas City?

A. It is practically between Kansas City, Missouri and Kansas City, Kansas. It enters the Missouri River above Kansas City, Missouri.

Q. What is the size of the Kaw River, doctor?

A. Well, I could not tell you.

Q. What is the volume of water?

A. I have no data at hand just now.

Q. Compared to the waters of the Missouri?

A. I have no data at hand just now to answer that.

Q. Have you ever had any data at hand?

A. No sir.

Q. Then if the size of the Kaw River was smaller than the Missouri River in comparison with the Missouri River, would not the high chlorines in the Kaw River go down when it reached the Missouri?

A. Yes sir, it would—they would.

Q. Wouldn't it have but little effect upon the Missouri if the Kaw River was comparatively a small creek or stream?

MR. WOERNER: In what respect?

MR. TODD: In comparison with the Missouri River.

MR. WOERNER: You mean as to chlorines?

MR. TODD: As to chlorines?

A. The analyses that I have made of the Kaw River and 2526 the Missouri River at the same time show a remarkable reduction in the chlorines, as compared with the Missouri and the Kaw after the two rivers meet. That is the Kaw River chlorines showing 100 parts per million. The Missouri River, after the Kaw river discharges into the Missouri, the Missouri River may show not more than 24 parts per million of chlorine.

MR. WOERNER: And how much above the Kaw?

A. And above the Kaw it might show 16. That would show an increase in the chlorines of the Missouri River resulting evidently from the mixing of the two rivers.

Q. MR. TODD: How far below the entrance of the Kaw into the Missouri were your samples taken?

A. Now they were taken several miles below Kansas City, Missouri.

Q. Several miles below?

A. Several miles. I cannot think of the exact number just now. It is in the record.

Q. You had your samples taken in the Kaw River?

A. Yes sir

Q. The size and volume of the water in the Kaw River you don't know?

A. No sir.

Q. And never did know?

A. No sir.

2527 Q. Then the next place that you took samples was below Kansas City?

A. Yes sir.

Q. And you instituted a comparison between the Kaw River and that point below Kansas City, did you?

A. Yes sir.

Q. That point below Kansas City had received the sewage of Kansas City in addition to the volume of water from the Kaw River, had it not?

A. Yes sir.

Q. Did you take a sample above Kansas City?

A. Yes sir.

Q. In the Missouri River?

A. Yes sir.

Q. How far above Kansas City was the sample taken?

A. It was taken half a mile above the waterworks of Kansas City.

Q. How far is that from the Kaw River?

A. Well, that I cannot tell you exactly.

Q. Well, approximately, doctor?

A. I think it is several miles.

Q. In your opinion at that point above Kansas City, do you believe that the waters of the Kaw River had completely mixed with the waters of the Mississippi?

2528 A. You mean the Missouri?

Q. The Missouri.

A. Well, that I couldn't say because I haven't made any observation to that effect.

Q. Do you know whether the samples taken above Kansas City were taken nearer the shore where the Kaw river enters the Missouri River or in the channel or nearer the opposite bank?

A. The waters were collected by my collector and the orders were for him to collect all the samples, to take the samples from the channel.

Q. Do you know whether that was done?

A. Well, I think it was; I considered the collector reliable, and that he did so.

Q. Has there any evidence been introduced on the record on that point, doctor; I don't know I am asking for information.

A. I don't think that question has been asked the respective collectors, but the collector himself has testified that he collected the samples and where he collected them.

Q. Now doctor, if that sample was taken—The Kaw River enters the Missouri from the North shore, dosen't it?

A. The Kaw enters it coming from the west.

Q. If that sample was taken two or three miles below the Kaw River near the west shore of the Missouri River, it would be mostly Kaw River water, wouldn't it? 2529

A. Well, that would depend upon the volume of the Kaw River on those days as compared with the volume of the Missouri River.

Q. Would the Kaw River waters commingle completely with the Missouri River three miles below its entrance into the Missouri River at the point where the sample was taken?

A. That I couldn't tell. I haven't made any observations of that kind.

Q. Where was this sample taken between the mouth of the Kaw River and Kansas City, Missouri. I want to localize that place, doctor?

A. Well now the samples to my knowledge were collected only above Kansas City, Missouri.

Q. Let me ask you a question there. Was the sample that was taken above Kansas City, Missouri taken below the mouth of the Kaw River?

A. No sir, above the mouth of the Kaw River.

Q. Above the mouth?

A. Yes, a half mile above the waterworks which are located above the Kaw River and above Kansas City, Kansas.

Q. Above Kansas City Kansas?

A. Yes sir.

2530 Q. I had it wrong; I thought it was below the mouth.

A. No sir.

Q. Now you took a sample in the Kaw River before it empties into the Missouri?

A. Yes sir.

Q. You took a sample in the Missouri River above the point where the Kaw River enters the Missouri?

A. Yes, and above Kansas City, Kansas and the waterworks.

Q. That is the one I mean. The one above Kansas City, Kansas, is above the entrance of the Kaw River into the Missouri.

A. Excluding all the sewage from Kansas City, Kansas, and Kansas City, Missouri and excluding the Kaw River.

Q. Let me get those points located, doctor. That's what I want to get; then we will get at the other.

A. Yes sir.

Q. The Kaw River is above Kansas City, Missouri?

A. Yes sir.

Q. And is below Kansas City, Kansas?

A. Yes sir.

Q. And its confluence with the Missouri River is between those two cities?

A. Practically, yes sir.

2531 Now one sample was taken in the Kaw River above Kansas City, Kansas, in the Kaw River, the only sample?

A. Yes sir.

Q. Now did you take a sample above Kansas City, Missouri and below the entrance of the Kaw River in the Missouri River?

A. No sir.

Q. Then you took a sample below Kansas City, Missouri?

A. Yes three samples altogether.

Q. Now the sample that you took above the Kaw River in the Missouri River; does that show high chlorines?

A. It showed on the day of collection, one day it showed 16 parts per million.

MR. WOERNER: Is that the highest?

A. No, it showed higher yet on another occassion.

Q. MR. TODD: On the day that sample was taken, was the sample taken in the Kaw?

A. Well, it couldn't have been taken on that same day; it is either on the preceding or the following day if not on the same day. I couldn't recall at this moment.

Q. The sample taken in the Kaw showed high chlorines, didn't it?

A. Yes, on one day 100 parts per million of chlorine.

Q. Now after the Kaw River entered the Missouri and before it reached the sewage of Kansas City, Missouri,
2532 you didn't take a sample at that point then, did you?

A. Yes, that was the only sample taken in the Kaw River, it was taken at Argentine, Kansas.

Q. No, in the Missouri before the sewage of Kansas City, Missouri entered the Missouri River, you didn't take a sample above Kansas City and below the mouth of the Kaw?

A. No, I did not.

Q. Now if the Kaw is a small stream in comparison with the Missouri River, the waters of the Kaw becoming commingled with the waters of the Missouri, the chlorine would be reduced considerably, wouldn't it?

A. Yes the analytical results of those days showed that.

Q. Then if that be true, the sewage from Kansas City, immediately below Kansas City at the point that you took the next sample would add considerably to the chlorine of the Missouri River, wouldn't it?

A. If the Missouri River would be low on that date of collection, naturally the quantity of chlorine coming from the Kaw River would have a smaller volume of water to mix with and the chlorines would show high at the point below Kansas City, but if the volume of water was large and the stage of the river high, was very high, the stage of the Missouri on the day that
the samples was taken, the quantity of chlorine coming
2533 from the Kaw river on that day would mix with so much
water that the result would show low, and the chlorine
does that

Q. How about the chlorine that comes from the sewage of Kansas City?

A. That would apply in the same way as the chlorines coming from the sewage.

Q. What fraction of increased chlorines below Kansas City, is due to the Kaw River and what became of the sewage of Kansas City, on those days that samples were taken?

A. On those days that samples were taken, one day showed the chlorines above Kansas City to be, I believe, 16. I have not got the data at hand just now. I am speaking from memory I am not positive that I am correct.

Q. I would just as soon have the proportions, doctor, as the actual data.

A. And the Missouri River below Kansas City showed 24 parts per million of chlorine, which showed an increase of one-third in the chlorine, from 16 parts per million, to 24 parts per million.

Q. That one third increase is due to what, the Kaw River, or the sewage of Kansas City?

A. Well since on that day the Kaw River showed very high chlorines, I don't know whether it was 80 parts per million
or 100 parts per million on that day, the conclusion could
2334 be drawn that so much chlorine coming from the Kaw
river into the Missouri River would affect the quantity of
the chlorine found in the Missouri River below Kansas City.

Q. Suppose that the Kaw River only emptied about 200 cubic feet of water per second into the Missouri River; would that conclusion be justified?

A. That would depend upon the volume of water in the Missouri River; the relative proportion of the dilution there.

Q. Then, in order to draw that conclusion, isn't it necessary to know the volume of water in the Kaw River as well as the volume of water in the Missouri River?

A. It would certainly enable definite conclusions.

Q. In the absence of the volume of water in the Kaw River, and the volume of water in the Missouri River, is the conclusion based upon proper facts?

MR. WOERNER: There wouldn't be any river under those circumstances.

MR. TODD: In the absence of the known volume in the Missouri and the known volume in the Kaw, can you draw a conclusion, and are you justified in drawing a conclusion such as you have?

A. Yes, I think I am, because if there is such a tremendous
2535 amount of chlorine found in the Kaw River there, and the Kaw River empties into the Missouri River, the chlorine has got to show in the Missouri River, and it is a natural conclusion to be drawn, that the chlorines found in the Missouri River must increase as the result of the discharge of water from the Kaw River showing such enormous quantities of chlorine as on the two days when samples were collected from the Kaw, 80 parts per million of chlorine per million on one day and 100 parts per million on another day.

Q. Doctor, in the absence of the known volume of the Missouri and of the Kaw, do you take into consideration the sewage contamination from Kansas City, Missouri, and Kansas City, Kansas, as to the chlorines?

A. Well, I did not in this case.

Q. Wouldn't it have been fair to have done that?

A. I admit that a definite conclusion could have been drawn if the quantity of chlorine coming from the sewage into the river could have been ascertained, but that was an impossibility, and on the other hand, the Kaw River showing such tremendously high chlorines, I considered it a natural conclusion that there must be some effect of the high chlorines in the Kaw on the increase in the Missouri River.

Q. Then drawing your conclusions you eliminate the

2536 volume of water in the Kaw, the volume of water in the Missouri and the sewage of Kansas City?

A. As I said, I based conclusions that I drew on the high chlorines in the Kaw River which had to go somewhere, and to show their effect on the Missouri River.

Q. Did you eliminate those three elements that I speak of in arriving at your conclusion?

A. I say that more accurate conclusions could have been drawn if all those facts could have been ascertained, and in conjunction with the fact of those high chlorines in the Kaw River, should have been taken into consideration

Q. My question is, did you eliminate those three essential facts from your opinion or conclusion; did you not?

A. Yes sir.

Q. In order to ascertain whether the chlorines below Kansas City are there from the Kaw River, wouldn't it be absolutely necessary to know the volume of the Kaw, the volume of the Missouri and the amount of sewage discharged from Kansas City?

MR. WOERNER: One moment, Mr. Todd, if you will permit the interruption.

MR. TODD: Surely.

MR. WOERNER: I would like you to say, when you say 2537 it is necessary to know, just whether you mean the precise quantities of water in each or whether the witness could make a determination from his general knowledge of the water in those two streams.

MR. TODD: I will ask him if he has any general knowledge.

MR. WOERNER: I wish you would.

MR. TODD: I have already asked him and he said he had not.

MR. WOERNER: That is the point I am getting at. What I am getting at is this. When you say you know what the volume of the water is in the Kaw River, the witness interprets that as understanding it: Do you know the amount of cubic feet going in there, but I understand he is not absolutely without knowledge as to the volume of water in the Kaw river or in the Missouri River.

MR. TODD: I will find that out.

MR. WOERNER: I wish you would.

MR. TODD: Doctor, do you know the volume of water in the Kaw River.

MR. WOERNER: Did you ever see it?

A. Yes, sir; I saw it.

MR. WOERNER: Why don't you say so?

MR. TODD: Do you know the volume of water that enters the Missouri River at the mouth of the Kaw?

A. No, sir; I do not.

2538 Q. Do you know the volume of water in the Missouri River above Kansas City, Missouri?

A. Yes, sir.

Q. What is the volume of water?

A. Well, the volume of water varies considerably, it may be 100,000 cubic feet and it may be 600,000 cubic feet per minute. It just depends upon the conditions in the upper Missouri River valley, which is a very long valley.

Q. You have no accurate data as to the Kaw?

A. No, sir; I have not.

Q. Have you any accurate data as to the volume of sewage that enters the Missouri River from Kansas City, Missouri and Kansas City, Kansas?

A. No, sir; except that I have ascertained from the city engineer of the City of Kansas, that only 60 per cent. of the population drains sewage into the river directly.

MR. JEFFRIES: You said the City of Kansas.

A. I mean Kansas City, Missouri.

Q. MR. TODD: Do you have any accurate knowledge as to the volume of that sewage based upon that percentage?

A. No, sir; not just at hand, but it could be estimated, based on the water supply.

Q. Have you knowledge sufficient so that you could take that amount of sewage into consideration in order to ascertain the percentage of chlorine pollution in the Missouri below Kansas City? 2539

A. No, sir; I cannot.

Q. In order to draw a conclusion as to whether the chlorine below Kansas City, comes from the sewage of Kansas City Missouri, and Kansas City, Kansas, or from the Kaw River, isn't it important to know the volume of the Kaw and the amount of sewage discharged into the Missouri from Kansas City, Missouri, and Kansas City, Kansas.

A. It would enable an absolutely accurate estimation.

Q. Your conclusion, then, is not accurate, is it?

A. Well, I consider it an approximation.

Q. Well, doesn't a conclusion that you could call approximate, in the absence of those two elements that I have spoken of —it isn't a conclusion that you would call approximate, is it, doctor, in the absence of those two elements that I have spoken of—the Kaw and the sewage from Kansas City?

A. I would call it only an approximation because of the natural conclusion that the Kaw River having so much chlorine, the chlorine in the Missouri River must be increased somewhat.

Q. Well, if the Kaw River was only a river of two or three hundred cubic feet per second, emptying into the Mis-
2540 souri, the volume as you have indicated, wouldn't that dilute the Kaw River so much as to make a great reduction in the chlorines of the Kaw as manifested in the Missouri River?

MR. WOERNER: You mean, wouldn't it dilute—

A. The chlorines in the Missouri?

MR. TODD: No, the chlorines in the Kaw, flowing into the Missouri would be reduced by dilution?

A. Yes, sir.

Q. Enormously, wouldn't it?

A. Yes. Those very analyses that I presented show that they are reduced from 100 in the Kaw to 24 parts per million in the Missouri, which is an enormous dilution.

Q. Can you state what proportion of the increase of chlorines below Kansas City is due to the Kaw water, and what to the Kansas City sewage?

A. No, sir; I cannot.

Q. Do you know whether 90 per cent. of it is due to sewage or not?

A. I don't know.

Q. Now, if you don't know what proportion is due to sewage in your analyses at Bellefontaine, can you ascertain there what proportion of the chlorine is due to sewage contamination and what to the Kaw River?

A. As I already said, that since the Kaw River showed 2541 chlorines varying from 80 to 100 parts per million on two particular days, and since these chlorines go into the Missouri River, if the Missouri River is not high the ratio of dilution would be small of that chlorine in the Missouri River and the Missouri River chlorines between Kansas City and Bellefontaine, would show an increase. The lower the Missouri River would be, the higher would be the increase in chlorines from the Kaw River chlorines. The higher the Missouri River would be of course, the lower the chlorines would be. Now, on those few days that samples were collected from the Kaw River and the Missouri River at Kansas City, the Missouri River was high and the dilution was great so that the increase was only one-third, no matter where that increase came from, the increase was very small but the conclusion could be drawn from the conditions prevailing in the Missouri River at times of low stage when the high chlorines of the Kaw river wouldn't find much water in the Missouri River for dilution, so that the chlorines of the Kaw River must of necessity then, affect the chlorines of the Missouri River and show high, and they showed very high at times at Bellefontaine. They showed as high as 35 and 36 parts per million.

Q. Wouldn't the same condtions obtain if the sewage discharge of Kansas City into the Missouri River when it 2542 was low, would be evidenced by high chlorines, and when high, by low chlorines?

A. Yes, it would depend upon the stage of the river and the volume of the water.

Q. Why is it, in your conclusions, doctor, you do not take into consideration the sewage of Kansas City?

A. Because such high chlorines as found in the Kaw River and that water discharging into the Missouri River, those chlorines must go somewhere. They are in the water and just according to the stage of the Missouri River they must increase the chlorines of the Missouri River proportionately. As I said, it may be that the Missouri River is so high that the dilution of the chlorines of the Kaw River in the Missouri is so great that the effect may be very slight if noticeable at all. It depends upon the volume of water coming down the Missouri River.

Q. Doctor, why didn't you take into consideration the sewage from Kansas City, in your conclusions in regard to chlorines?

A. I have no available data. I couldn't obtain them and it would have necessitated an investigation which I couldn't undertake at that time, and then seeing or noticing the high chlorines in the Kaw River and calculating on a natural increase of chlorines, and in a degree depending upon the Missouri River stages, I calculated that some effect of the Kaw River
2543 chlorines must be estimated for the Missouri River, varying more or less, according to the stage of the Missouri River.

Q. Your inability to get the data of Kansas City, do you consider that a justification for the elimination of the sewage of Kansas City from your consideration?

A. Not at all times.

Q. At any time, at any one time?

A. There may be occasions when the stages of the river enable a dilution that neither the chlorines of the Kaw River, nor the chlorines from the sewage of Kansas City will show any effect there on the Missouri River.

Q. When was that period that you have just spoken of?

A. The period when we took the samples and during the time when the Missouri River was high.

Q. And was that a time such as you have indicated when the Kaw River and the sewage of Kansas City had no effect upon the Missouri?

A. No, not such a very high stage, but a high stage to account for the tremendous dilution of the Kaw River chlorines in the Missouri River.

Q. That is, an exceptional condition rather than a general condition, of the Missouri River, isn't it?

A. Well, that I couldn't tell off-hand, without studying
2544 the stages of the Missouri River very carefully.

Q. But in none of your investigations have you taken into consideration the sewage discharge of Kansas City, have you?

A. I have not in calculating the chlorines for the Missouri River.

Q. I am talking about the chlorines.

A. Yes, not in connection with the chlorines.

Q. And was it because you did not deem that essential for your consideration, that you didn't take it into consideration?

MR. WOERNER: Let the question be repeated, digest it and then answer it.

Q. (Question repeated.)

A. I would have preferred a careful scientific investigation of the amount of chlorines going into the Missouri River, but since on the two occasions that samples were taken from the Kaw River, the Kaw River showed such enormously high chlorines and the Kaw River below Kansas City showed an increase notwithstanding the fact that the Missouri River was very high, producing great dilution of the Kaw River chlorine, I consider the conclusion in that instance as an approximaion of the character of the chlorines in the Missouri River as sufficient.

2545 MR. JEFFRIES: I object to the question and answer and move that both be stricken out, because it is incompetent, irrelevant and doesn't tend to prove any issue involved in this case.

MR. TODD: I move to strike out of his answer all in regard to the Kaw, which is not responsive to my question.

Q. And was it because you did not deem that essential for your consideraton, that you did not take it into consideration, the sewage discharge of Kansas City?

A. It was because I couldn't obtain the data.

Q. And not being able to obtain the data, you eliminated it entirely from your consideration, didn't you, doctor?

A. I relied upon the condition of the Kaw River as found to justify an approximate conclusion.

Q. And eliminated the sewage from Kansas City from any consideration?

A. Yes, sir.

Q. Can you tell me what proportion—you made an examination of samples below Kansas City, did you not?

A. Yes, sir.

Q. From that examination what proportion of the increase of chlorines was attributable to the Kaw River and what to Kansas City, do you know?

MR. JEFFRIES: Object to the question for the reason 2546 that he has already said that he didn't take into consideration the sewage discharge from Kansas City.

Q. MR. TODD: Do you know? That can be answered yes or no, doctor?

A. Well, I have already testified that I attributed—

Q. (Question repeated.)

A. At low stages of the Missouri River the Kaw River chlorines will affect the Missouri River chlorines—

MR. WOERNER: How do you know it, that it all didn't come from Kansas City instead of from the Kaw River?

A. Well, I made no investigations and that's why I couldn't tell.

Q. MR. TODD: Then you don't know?

A. For those two samples that were collected on those two days—

MR. TODD: Then you don't know what proportions of the chlorines below Kansas City came from Kansas City and what came from the Kaw River, do you?

A. Not from any investigation of the Kansas City sewage.

Q. Do you know from any investigation the proportion of the increase of chlorines below Kansas City that is due to the Kaw River water and what is due to Kansas City sewage?

A. How much of each I have not estimated.

2547 Q. Do you know? Not what you have estimated?

A. Well, I couldn't know from any original data except that I can draw an approximate conclusion for low water stages.

Q. Independent of conclusions, do you know what fraction of the increase of chlorines below Kansas City is due to the Kaw River and what to the Kansas City sewage?

A. As applied to the analyses made of certain samples? Do you mean it that way?

Q. Yes. Or from any other information that you have got; do you know?

A. Well, as applied to the conditions prevailing on those days that those samples were collected, I couldn't tell.

Q. And you have no other source of information except the samples that were taken upon those days, have you?

A. No direct information.

Q. Now, the chlorines that you found at Bellefontaine, you are unable to say what proportion of those comes from Kansas City sewage and what proportion comes from the Kaw River, are you?

A. I feel justified when the Missouri River is low, and I find high chlorines at Fort Bellefontaine, that those chlorines can come from the Kaw River chlorines largely, if not altogether.

2548 Q. Can you say whether the chlorines that you found at Bellefontaine, that 90 per cent. of it doesn't come from the sewage of Kansas City?

A. At low stages of the river I think that it does not.

Q. I am not asking you about the stages.

A. That 90 per cent. does not. It depends upon the conditions of the river.

Q. Have you ever made any analytical data for the purposes of ascertaining the proportions of chlorines that emanate from the sewage of Kansas City and from any other sources of information, are you able to state that 90 per cent. of chlorine in the river at Bellefontaine does not come from the sewage of Kansas City?

A. I couldn't say that because the quantities of chlorines vary almost daily at Fort Bellefontaine and no conclusion would be possible on the basis as you direct the question to me.

Q. Assuming that 90 per cent. of the chlorines found at Bellefontaine comes from the Kansas City sewage would that have any effect upon the potability of the waters of the Missouri?

A. Not unless corresponding high nitrites and correspondingly high free ammonias would be shown.

2549 Q. If correspondingly high nitrites and correspondingly high free ammonias were shown, and the albuminoid ammonias you were not able to ascertain whether they were from animal or vegetable origin, could you tell?

A. And how much chlorine would be in that calculation?

Q. The amount which you found by your analyses. Would you denominate that water potable?

A. If the nitrites were high and the chlorines were high and the ammonias were high and I was personally convinced that the chlorines were due to sewage and not from the Kaw River, I would say according to the axiom of sanitary science that the water was not potable. The mere analytical facts of high nitrites and high chlorines and high free ammonias and the high chlorines being proven to come from sewage pollution, that in itself, those three things together would condemn that water as not being potable, certainly.

Q. Can you, doctor, say that the scientific fact that the albuminoid ammonia found in suspension or in solution demonstrates without a doubt that its origin is animal and not vegetable?

A. If not corresponding with the high chlorines and the high nitrites and the high free ammonias it could not be shown that the high albuminoid ammonia is due to animal pollution.

2550 Q. Can it be shown that it is due to vegetable pollution?

A. In many instances, it can be shown, yes.

Q. And in many instances it cannot be shown, is true, too, isn't it, doctor?

A. Well, the point is this, that all instances that I have familiarized myself with by the study of analytical investigations not only of my own, but of other people; they have all justified the conclusion that the high albuminoid ammonia found in itself with further ingredients of pollution being low, is usually of vegetable origin. As I said before today, Professor Drown has practically established that as an axiom of sanitary science in judging water. He thinks less of the albuminoid determination than of any other in figuring sewage pollution.

MR. TODD: I move to strike out all that he states about what other professors have stated, as not being responsive to my question.

Q. The slaughterhouses of Kansas City empty a great part of the sewage which turns into albuminoid ammonia, doesn't it, doctor?

A. Yes, sir.

Q. That is sewage from animal and man emptied into the Missouri River above Fort Bellefontaine, isn't it?

A. Yes.

2551 Q. Now, can you, as an analytical chemist, differentiate in percentages the amount of albuminoid ammonia in suspension or in solution that is attributable to animal origin and to vegetable origin?

A. The animal origin is only existing for the high albuminoid ammonia as accompanied by high nitrites and high chlorines and high free ammonias—they go together to characterize water as sewage polluted.

MR. TODD: I move to strike out the answer as not responsive and ask to have the question re-read.

Q. (Question repeated.)

A. In percentages, no, sir.

Q. You cannot tell whether the albuminoid ammonia found in the Missouri River, whether 50 per cent. is attributable to vegetable or animal origin, can you, doctor?

A. No, not by my calculation, getting it down to such figures.

Q. Then if the albuminoid ammonia should be of animal origin and accompanied by high nitrites and nitrates and free ammonia and high chlorines, the water wouldn't be potable, would it?

A. It would not if accompanied by those high other ingredients you mention.

Q. If the high albuminoid ammonia came from vegetable origin there is nothing that would render it impossible to 2552 be accompanied by high nitrites, nitrates and free ammonia, is there?

A. The water collected from the station at Bellefontaine—

Q. (Question repeated.)

A. I want to exemplify it.

MR. TODD: Answer it first and exemplify it afterwards.

Q. (Question repeated.)

A. It wouldn't be possible if high chlorines were going with it.

Q. I didn't ask about the chlorines, doctor.

A. Well, in order to determine the potability, chlorines would have to be taken into account.

Q. Well, if the chlorines came from the Kaw River, they could be high and yet that condition could exist, couldn't it?

A. You mean what condition?

Q. That is, you could have albuminoid ammonia in suspension or solution accompanied by high nitrites, nitrates and free ammonia, could you not, if it was of vegetable origin?

A. If it were of vegetable origin?

Q. Yes, could that condition obtain?

A. Hardly, at Fort Bellefontaine.

Q. Anywhere?

A. Some places, yes.

Q. It could obtain in the Illinois River, couldn't it?

2553 A. Yes.

Q. But it couldn't obtain in the Missouri River?

A. Well, it could obtain in the Missouri River, but it doesn't obtain at Fort Bellefontaine where we took our samples.

Q. I am speaking of it as a principle, doctor, as applicable to any place.

A. You cannot apply that to all places, that principle.

Q. Hypothetically I am speaking, doctor.

MR. WOERNER: When you put in the Missouri River, that eliminates the hypotheses.

A. Not even hypothetically.

Q. MR. TODD: Then that condition couldn't obtain in the Missouri River?

A. Not with the conditions prevailing in the Missouri River.

Q. That is, you couldn't have high ammonia in solution and in suspension in the Missouri River from vegetable origin?

A. Yes, you could have that.

Q. Then could you have high nitrites?

A. I never found high nitrites in the Missouri River. There are no high nitrites in the Missouri River.

2554 Q. The nitrates?

A. The nitrates are high.

Q. The nitrates are the second stage to nitrites, aren't they?

A. It shows that the process of oxidation of the water and purification has reached a permanent stage; that is, it is completed and gives the water a character of stability.

Q. And you could have free ammonia?

A. Yes, sir.

Q. If you have high albuminoid ammonia in suspension or solution, that condition obtains in the Missouri River, doesn't it?

A. High ammonia?

Q. High albuminoid ammonia?

A. And what else?

Q. And high free ammonia?

A. Yes, sir.

Q. Now, the free ammonia, when the processes of disintegration takes place turns into nitrites, doesn't it?

A. Yes, sir.

Q. And the nitrites carry on in the nitrates?

A. Yes, sir.

2555 Q. What is the reason, doctor, that when you have free albuminoid ammonia, and free ammonia and nitrates, high nitrates, that you don't have high nitrites?

A. That shows that the processes of purification, for part of the pollution, has reached the stage where it has been completed and the high nitrates demonstrate that, and the low nitrites demonstrate that, because if the nitrites were high this process of purification would still be going on for pollution of a certain kind.

Q. What do the nitrites come from, doctor?

A. They come from nitrogeneous matter in the water, and the oxygen.

Q. Known as what?

A. Well, as nitrites.

Q. No, I mean the nitrogenous matter in the water is known as what?

A. Well, the organic matter.

Q. Free ammonia?

A. Carbonate of ammonia, yes.

Q. That is what is known as free ammonia?

A. Yes, sir.

Q. Now, the free ammonia is constantly undergoing a change in water, isn't it?

A. Yes, sir, they are.

Q. And that is forming nitrites?

2556 A. Yes, sir.

Q. And the nitrates are formed from the changes from nitrites to nitrates?

A. Yes, sir.

Q. Now, if you have got free ammonia in large quantities, I mean chemically speaking, and the changes are going on with that free ammonia, that changes to nitrites, doesn't it?

A. Yes, sir.

Q. Do the nitrites change to nitrates quicker than the free ammonia to nitrites?

A. Well, that couldn't be established.

Q. It could not be established?

A. No. I know of no investigations that have resulted in figuring the ratio of time there.

Q. If you have high ammonia and high nitrates, musn't there be an intermediate stage of high nitrites?

A. No, sir, not necessarily, the analytical results of many investigations show that high nitrites are not there; it isn't necessary.

Q. Well, they have been there sometime haven't they?

A. Sure, but they have been converted into the final product in the cycle of nitrification to nitrates, so that the pollution has been disposed of. It has resulted in converting the various
ingredients which are characteristic of the pollution into
2557 the final produce of nitrates.

Q. So that when you find free albuminoid ammonia and free ammonia and nitrates, the conclusion chemically speaking will justify that the nitrites have changed to nitrates more rapidly than the free ammonia to nitrites, isn't it?

A. Not at all, because the free ammonia may come from various sources.

Q. Whatever sources it comes from, it is there?

A. Yes, it is there. It is eventually converted afterwards according to the changes going on in that river.

Q. Now if you find in a river, albuminoid ammonia, I mean free ammonia, high free ammonia, high nitrates, low nitrites and high chlorines, wouldn't it be potable water?

A. That would depend upon the relative proportions of the ammonias and the chlorines, and the sources of the chlorines, but low nitrites in itself would demonstrate a character of stability in that water with the process of nitrification as being completed, and as giving the water a certain stability, less liable to changes and when that is found frequently as ascertained by daily analyses of samples, the conclusion is justifiable that the water is potable.

Q. Suppose that you didn't know the source of the chlorines and that condition obtained; wouldn't it be potable?

2558 A. I would still take into consideration the nitrites, the most important ingredient, because the potability of the water depends very much upon its stability or instability, that is, whether the fermentative changes that the organic matter undergoes, whether those fermentative changes have reached the stage that they are completed, which is demonstrated by the low nitrites and the high nitrates which is the case at that point.

Q. The nitrites whether high or low do not indicate whether they are from animal or vegetable?

A. Taken by themselves, they do not.

Q. Now if you have got high albuminoid ammonia, free ammonia, low nitrites, high chlorines and you don't know what the source of that chlorine is, would you say the water was potable or not?

A. I would base my judgment upon the conditions prevailing and the source of that high chlorine.

Q. No. But supposing I came to you and presented you with a sample of water and asked you for an expert opinion. The water is in a bottle. I refuse to tell you where I got the water from, but wanted to know whether the water was potable or not, and that the sample upon analysis disclosed albuminoid ammonia, high free ammonia, low nitrites, high nitrates and high chlorines?

2559 A. And low nitrites?

Q. Low nitrites.

A. I would say this is an exceptional condition—

Q. Wait until I finish my question. That would be what was disclosed by the water that I brought you. I would then ask you is that water a potable water or not, and ask you to answer me Yes or No? Could you answer it?

A. I would refuse to answer that question Yes, until I had ascertained why it was that the exceptional condition presents itself of water having low nitrites, high nitrates and high chlorines. That would demonstrate that the chlorine is due to some source of pollution not sewage pollution, and it would be necessary to ascertain where this high chlorine comes from, that can go together with low nitrites and high nitrates, because the pollution has been removed, of that water, to a very large extent as shown by the low nitrites and the high nitrates. The pollution would still be there because the presence of nitrites would show that the fermentative changes were still going on. Very low nitrites together with very high nitrates with the processes of purification to a large extent, to the largest extent of that pollution, had been completed, and the high chlorines would have to be investigated because it would be an exceptional condition. Where does the high chlorine come from?

2560 Q. Then if I refused that information to you, you would be unable to give me an opinion as to whether the water that was present in the sample was potable or not; is that correct?

A. I would refuse to do so with that information.

ADJOURNED until 2:15 P. M., Wednesday, April 1st, 1903.

2561 Southern Hotel, St. Louis, Missouri. 2:15 P. M., Wednesday, April 1st, 1903. Continuation after recess. Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for further cross-examination by Mr. Todd, and testified as follows:

Q. Doctor, are the waters of the Missouri River at Fort Bellefontaine what is known as stable waters?

A. Yes sir.

Q. What is the meaning of stability as applied to a river?

A. The words—or rather the term "stable" is applied to a river where the fermentative changes and the nitrification changes which the impurities in the river undergo, are more of a uniform character, and are going on in a manner that they do not change rapidly, and where analytical results show by low nitrites and uniformly low nitrites that the cycle of purification has reached a stage where a large portion of the impurities have been converted into nitrates,—the final product of the cycle of nitrification.

Q. In your examination of the waters of the Missouri at Fort Bellefontaine, what did you find as to the presence
2562 of albuminoid ammonia?

A. I found the albuminoid ammonia quite high.

Q. As to free ammonia?

A. I found the free ammonia as a rule, which I conisder low, but at times I found a slight increase in the free ammonia, where I would say that the free ammonia was there in a considerable quantity.

Q. As to nitrites?

A. The nitrites I found uniformly very low for a river—frequently absent.

Q. And nitrates?

A. Nitrates I found at times quite high, and at other times not so high—as a variation.

Q. And chlorines?

A. Chlorines I found high; sometimes as high as 46 parts per million.

Q. Was the Missouri River a polluted stream based upon your chemical analyses?

A. You mean at Fort Bellefontaine?

Q. At Fort Bellefontaine?

A. Yes sir.

Q. And to what extent was it a polluted stream, doctor?

A. Well, whenever it would show the presence of free ammonia, and albuminoid ammonia and nitrites—further-
2563 more when the oxygen consumed test would show organic
matter present—the opinion is justified that the water was polluted.

MR. JEFFRIES: Now he asked you to what extent doctor. Why don't you say to what extent?

A. To what extent?

MR. JEFFRIES: Yes?

A. Well, that is variable. You could not define it. That is, you could call it a polluted stream. I would not call it a very polluted stream.

Q. MR. TODD: To what do you attribute the pollution?

A. Well, that depends upon the seasons and depends upon the times when the sample is analyzed.

Q. My question is to what do you attribute the pollution?

A. I attribute it to organic matter of vegetable origin, and organic matter of animal origin,—the degree of each varying.

Q. Are you able to state from your analyses the extent of pollution attributable to vegetable origin and to animal origin?

A. I would say that during the summer months—

Q. Doctor, you don't get my question. Read my question. (Question read.)

A. Approximately, yes.

Q. To what extent was the stream polluted by pollution due to animal origin?

2564 A. At what time of the year, because that varies according to the seasons and the weather?

Q. Well at any time of the year during which you made the examinations?

A. Well, there are changes produced resulting in variations that make it difficult there to answer that question directly.

Q. Were there times when the pollution was greater from animal origin than from vegetable origin as disclosed by your analyses?

A. Applying the same principle in determining the vegetable origin of the organic matter, I would also say that whenever the albuminoid ammonia in solution runs very high with the organic matter—as estimated by the oxygen consumed process, high and the nitrites, although uniformly low, would still show their presence by a figure showing that there was still fermentative changes going on at that time,—at such times I would say that the pollution could be of animal origin.

Q. At those times was the river potable?

A. At such times it was not potable.

Q. During what periods of the year, or how much of the year did conditions such as you have described obtain, in the Missouri River at Fort Bellefontaine?

A. Well they would appear during the winter months.

2565 Q. And during the winter months beginning with what month, doctor?

A. Well, there is a gradual increase in the impurities of every river during the fall months and also of the Missouri River, that is when the colder weather sets in the processes of purification in the rivers are retarded. The plant life is greatly inhibited by the cold weather, and the absorption of impurities by the plants is of course proportionately decreased. Furthermore the bacteriological purification going on in the river of the organic matter also lessens with colder weather, and with the approach of cold weather in the fall gradually there is an increase of the impurities taking place.

Q. And are those winter months—Of those winter months how many do you estimate are contained in the period that you described in the preceding answer?

A. Well, there is a transitory period in the fall and in the spring months that depends upon the special weather conditions at that time, whether there is a warm fall or not. If there is a warm fall of course then retardation of the purification and oxidation processes sets in later; as long as the warm weather prevails, so long will the purification processes be hastened by this condition.

Q. How many months are considered as winter months in this climate?

2566 A. Well, as absolutely winter months, I would consider from three to four months. We may have winter weather for three months, and we may have winter weather for four months.

Q. Well then, during those four months, this condition of pollution that you have described as being attributable to animal origin, obtains in the Missouri River?

A. Yes sir, the only way that we have of differentiating between vegetable and animal origin,—that very principle applied would demonstrate animal origin during those winter months.

Q. And during that time are the waters of the Missouri potable?

A. No sir.

Q. Then when you stated in your testimony yesterday that the Missouri River was potable throughout the year, you eliminated from your consideration the four winter months during which animal contamination existed in the Missouri?

A. I am very glad you brought that matter up, because if I said throughout, I did not mean to say that; what I meant to say, was prevailed during the year, in taking the larger part of the year when I think the water is potable, but for those four months I do not consider it potable.

Q. Those four months or three months, as the case may be, you can ascertain chemically that the waters of the
2567 Missouri River are not potable?

A. Yes sir.

Q. As to the other eight or nine months of the year when you claim that the water is potable, that condition you ascertained by chemical analyses?

A. Yes sir.

Q. Have you ever supplemented your chemical analyses by any bacterial investigation?

A. Yes sir.

Q. Are the waters of the Missouri River bacterially pure?

A. No sir.

Q. Are not the bacilli coli communis prevalent in the Missouri River in large quantities throughout the year, as evidenced by the bacteriological examinations and the tables that have been introduced in evidence?

A. I consider them smaller during those summer months than in the winter months.

Q. Well, smaller is a relative term.

A. Which deductions I have drawn from bacteriological reports that I have seen.

Q. And do you consider the presence of these bacteria in the quantities in which they appear, as evidenced by the tables that have been introduced here, in evidence, as being in
2568 such insufficient quantities as to not affect the potability of the waters of the Missouri?

A. As compared with the chemical analyses indicating during the summer months very little, if any, sewage pollution of the water at Bellefontaine, the high counts,—the total counts of bacteria could not, in my opinion be ascribed to the prevalence of such bacteria as are found in sewage because the water as it is found there at Bellefontaine does not appear to be sewage polluted during the summer months.

Q. Whenever the bacillus coli communis is found in water, what does the presence of that bacteria indicate?

A. The presence of that bacteria may indicate either sewage pollution if corroborated by chemical analyses, or may indicate fecal discharges of fish.

Q. Are there many fish in the Missouri River?

A. Yes sir.

Q. And do you attribute the presence of these coli bacilli to fish in connection with your chemical analyses?

A. Well, since investigations have determined that fish have in their fecal discharge the colon bacillus, and if the chemical analysis does not demonstrate sewage pollution of the water the conclusion may be reached that sewage not being identified as present by the chemical analyses, the presence of the bacilli coli communis may be ascribed to the fecal discharges of fish. 2569

Q. Doctor, has it been scientifically ascertained how the coli communis bacilli get into fish?

A. That is a question that would not come into consideration there in ascribing the presence of the coli communis to the fecal discharges of the fish, since it has been proven by scientific researches, that the bacillus coli communis is present in the fecal discharge of fish.

Q. And has it been proven that that bacilli is present in fish in streams other than sewage contaminated?

A. Well, it is some time ago since I have studied data and reports on such investigations, and at this moment I cannot remember that, but it is very likely that since I based my conclusions at that time on a careful study of that question some time ago, that such investigations have been made.

Q. Then the presence of this bacterium has been scientifically demonstrated to be in the fecal discharge of fish?

A. Yes sir.

Q. And if, bacterially speaking, the coli communis is discovered in water, and that water is well stocked with fish, its presence there could be as scientifically accounted for as coming from the fecal discharge of fish as from sewage pollution, could it not?

A. Yes sir.

2570 Q. And there is no way of telling from a scientific standpoint whether this coli is the result of the fecal discharge of fish or of sewage, is there?

A. The investigations so far as I have been able to inform myself, have not reached that stage yet where that point could be settled.

Q. Well, there is no mark or no peculiar attributes of these coli bacilli that marks it then as emanating from the fecal discharge of fish as different from the fecal discharge of animal or man, is there?

A. Not to my knowledge.

Q. Do you know of any bacteriologist who has made a careful bacterial analysis of the waters of the Missouri, that holds to the view that the Missouri River is a potable stream?

A. No sir, I do not know of any, at this moment.

Q. Do you know of any who hold that it is not a potable stream?

A. If there are any I am not familiar with their researches.

Q. Are you acquainted with the conclusions drawn by Dr. Ravold from the bacteriological examination which he made of the waters of the Missouri River as to whether or not it is potable?

A. Yes sir.

2571 Q. In getting your information as to the bacterial conditions of the Missouri River, what data have you consulted?

A. Dr. Ravold's data.

Q. The data that you consulted was the data that was compiled under the direction of Dr. Ravold, and which has been introduced here in evidence?

A. Yes sir.

Q. Outside of that data have you made any independent investigations on the line of bacteria in the Missouri River?

A. No sir.

Q. Do you agree with Dr. Ravold's conclusions?

MR. JEFFRIES: I would suggest that that is a repetition.

MR. TODD: I mean as to the Mississippi River, but not as to the Missouri.

MR. JEFFRIES: I thought you included both rivers at the time.

MR. TODD: No, I took them one at a time, because I couldn't carry both of them.

Q. Do you agree with Dr. Ravold's conclusions that the waters of the Missouri are not potable?

A. I will answer that question if the conclusions of Dr. Ravold are read to me so that I can compare his views with my views.

2572 MR. WOERNER: I object to the question that is asked on the ground that it is incompetent, immaterial and irrelevant, and would suggest that the doctor be asked as to the facts and what his conclusions are, and then whether they agree or not with some other witness, is a question for the Court.

Q. MR. TODD: From the data as compiled by Dr. Ravold, in regard to bacteria in the Missouri River, what conclusion do you draw from that data as to the potability of the Missouri River?

A. I consider the Missouri River potable during those eight or nine months that I have specified, as representing the warm season of the year—potable at Fort Bellefontaine.

Q. That is what I am speaking about, doctor.

A. Yes.

Q. What do the analytical data which you consulted, show as to the presence of bacteria during the other months in the Missouri River at Fort Bellefontaine?

A. Well now, to be accurate I would have to look over the tables presented by Dr. Ravold, because it is some time ago that I studied that table, and I formed a general conclusion at that time but, as to answering this question specifically, I would have to glance over the table again.

Q. You cannot give a general answer to the question?

A. No, it is some time ago since I studied that table and
2573 there were varying conditions there that necessitate a
close scrutiny of the data before forming an opinion.

Q. Do you know of any authorities that hold that sewage polluted streams are potable, bacterially?

MR. JEFFRIES: That is a repetition Mr. Todd.

A. Well that question cannot be answered, because the potability depends upon the chemical as well as the bacteriological conditions of the water.

Q. Can a bacteriologist pass judgment upon the potability of a stream?

A. Yes, he can in some instances. There are exceptions where water may be chemically pure and yet contain typhoid fever germs, as has been demonstrated by investigators, and that water of course would not be potable; but those are exceptions.

Q. Do you know of any bacteriologist who has discovered the germs of typhoid fever in running waters?

A. I know of some investigations where the typhoid bacillus was identified in the sediment found on the filter of a river water from a city water supply.

Q. Do you know of anyone who has discovered the bacillus of typhoid in running water?

A. If accepted under such conditions, that is, that the typhoid bacillus was identified in the sediment remaining on
2574 the filter when filtering a polluted river water, yes.

Q. I am not asking, doctor, about the discovery of typhoid germs on filters from water mains in cities. I want to know if you know of anyone who has discovered the germs of typhoid in running waters of rivers?

A. There have been investigations recorded in which it was claimed that this bacillus had been found, but the overwhelming evidence is to the effect that,—as far as I have been able to get the evidence from a vast amount of literature, that I have read, on the subject,—the overwhelming evidence is that the typhoid bacillus has not as yet been identified in running waters.

Q. Is the Missouri River a sewage polluted stream?

A. That depends upon what point—

Q. At any point from its source to its mouth, eliminating Bellefontaine.

A. Eliminating Bellefontaine?

Q. Yes.

A. Yes, at various points it is sewage polluted, wherever the sewage enters the river from cities along the line.

Q. Do you know of any standard authority upon the subject of running waters sewage polluted that holds to the potability of that water in such a stream?

2575 A. You mean potability of the Missouri River water?

Q. Yes. I will make it applicable to the Missouri.

A. No, as far as the Missouri River is concerned.

Q. Do you know of any scientific man who has investigated the waters of the Missouri that holds to the doctrine that it is potable, aside from yourself?

A. Well, if I understood the testimony of Professor Keiser, correctly, Professor Keiser testified to that effect.

Q. He didn't touch on the bacteriology of it, did he?

A. Well, you are speaking of potability. You did not specify bacteriologically.

Q. Yes, but as applying it as to bacteriology. I am examining you now as a bacteriological expert.

A. Well, bacteriologically, I mean to say from a bacteriological standpoint alone, a running river should not be judged as to its potability. The chemical conditions should be taken into consideration.

Q. Do you know of any other authority on bacteriology that holds that the Missouri River is potable—is a potable stream aside from yourself?

A. Bacteriologically?

Q. Yes?

A. No, I cannot recall any to my mind just now.

2576 Q. Doctor, how do you account for the Missouri River being a stable river with the presence of albuminoid ammonia, and nitrates and chlorine present there in the quantities that you have indicated?

A. Because first of all, the free ammonias are comparatively low during the larger part of the year, and secondly the nitrites are low, they are frequently absent, and the nitrites high, and the free ammonias not being high at such times, justifies the conclusion taking into consideration also that during frequent periods of the year when the river is low, that the high chlorines may be attributable to the Kaw River. Taking all these facts into consideration, the stability of the river is established by the remarkable uniformity of these impurities throughout long periods. They don't fluctuate so much, the impurities, they do not change so much. There is a stability established there by the uniformity of the nitrites from being uniformly low, to only being present in traces, or being absent entirely. The nitrates being uniformly high and the free ammonia being uniformly low, and the chlorines as I said, during just such periods of low stages of the river, when they are high, being atributable to accessions from the Kaw River.

Q. If you assume that the presence of cholrine was not due to the Kaw River, but to the sewage contamination of
2577 Kansas City, would that change your conclusions as to its stability?

A. No sir, not unless all the conditions as I described, that had to be taken into consideration when you judge the potability of that water. Not unless all the conditions would point to sewage contamination.

Q. Well, assume that all the conditions that you found existed and that you are mistaken about your deductions in regard to the Kaw River, but that the chlorines are attributed to the sewage of Kansas City, and the other cities along the banks of the Missouri, would that change your opinion as to the stability of the Missouri River at Bellefontaine?

A. But that would be a strictly theoretical condition which I never found to exist during my investigation.

Q. Assume that it exists?

A. Well, that would be strictly a hypothetical question.

Q. Consider it as a hypothetical question.

A. Not based upon any actual conditions found during many investigations and many samples collected and analyzed from the river.

Q. You don't object, do you doctor, to the elimination of the Kaw River from your answer?

A. I said from a hypothetical point of view.

Q. I am putting it as strictly hypothetical as I know how, 2578 and assuming that the conditions existed there as you found them by your analyses and that the high chlorines that you found there were attributed to the sewage discharge of Kansas City, what would be your conclusions as to the stability of the Missouri River at Fort Bellefontaine?

A. Even if those high chlorines would be—now this a theoretical problem.

Q. I so stated it.

A. Even if those high chlorines you mention there, were due to the sewage from Kansas City, after a run of 403 miles, even then it would be very difficult to ascribe such character to the water as you hypothetically present to me, as due to sewage pollution from Kansas City.

Q. Why, doctor?

A. For various reasons.

Q. Give the reasons?

A. First of all the distances from Kansas City to St. Louis would be 403 miles by water.

Q. Yes.

A. Only 60 per cent of the Kassas City sewage would go into the Missouri River. The Missouri River during its winding course with many curves, and as proven by the length of that river, 403 miles, where the air-line is much shorter, a great deal shorter, as proven, the character of the river not being 2579 regulated, that is, there being no dams or anything, the river overflowing frequently during its course, carrying a great deal of sewage over vast places there adjoining the river, and at a low stage of the river, as the river falls, much of this sewage never coming down the river, being left there in a condition of fermentation, on that soil, previously overflowed. It would be impossible to claim that any Kansas City sewage reached St. Louis or reached Bellefontaine.

Q. Then the conclusion is irresistable that the sewage of Kansas City has become purified before it reaches Bellefontaine in going a distance of 403 miles?

A. At certain times, when all of such conditions would prevail, as I describe, I would say yes.

Q. Isn't it at all times true, doctor, that when in high water it is deposited on the overflowed land and at low water stages it is left along the banks in its serpertine course towards Bellefontaine, so that under these conditions, the Missouri River that takes the sewage of Kansas City, has become pure, or has purified itself in going 400 miles? Is that true?

A. There may be exceptions because these conditions may not prevail throughout the year.

Q. Well, can you give me any reason for the exceptions, doctor?

(Question withdrawn).

2580 Q. Can you answer the question Yes or No and then give the exceptions?

A. Repeat the question.

Q. (Question repeated)?

A. Well, since you specify in that question when the sewage with the overflow of the water would be deposited on the land, on the soil and retained there after the fall of the river again, a considerable time having elapsed during all of this deposit of the sewage there, I could answer your question Yes, with such conditions prevailing.

Q. Are there any exceptions to that rule, doctor, that the Missouri River purifies itself in going 400 miles?

A. Well that I am not prepared to say because I found that during the winter months, the cooler weather retarding the processes of oxidation and mineralization of the organic matter in the Missouri River, I say that the chemical results of the analyses of samples showing at Fort Bellefontaine the same pollution of the water, I am not prepared to answer that question.

Q. The distance that the stream would purify itself from Kansas City, would depend upon the velocity of the current, wouldn't it?

A. Well, other conditions too.

2581 Q. Other conditions being equal?

A. The condition of the river itself, that is, in enabling the overflow over large banks.

Q. Well, it is a uniform rule, is it not, that the waters in the Missouri, with the higher stage of water, the swifter the current?

A. In the channel, yes.

Q. The lower the stage of the water the slower the current?

A. Yes sir.

Q. The high stage of water and the swift current is overcome by the sedimentation that takes place along the overflowed portion of the Missouri River in assisting purification; isn't that true?

A. Yes sir.

Q. Now if the current at low stages was decreased in velocity, purification would take place in going a lesser distance, wouldn't it?

A. Well now, the course of the river between Kansas City and St. Louis is so long that this principle cannot be applied to the entire route; it may vary along the route considerably.

Q. But if the sewage gets into the river that has a slow current, it will become purified in going a shorter distance than it would in going a longer distance with a swifter current, wouldn't it?

2582 A. That depends so very much upon the different conditions there prevailing in the river that you cannot apply that rule to every case; that is the way it seems to me.

Q. I am speaking of the Missouri River doctor, when the river is within its banks and the current is not as swift as it is at high stages, the time that it takes for purification may be the same, but the distance the water travels may be not so great isin't that true?

A. Compared with what?

Q. With its high stages?

A. Repeat the question.

Q. It takes a certain period of time for the purification of that sewage, doesn't it?

A. Well, a certain time. I couldn't say. It takes time, but how much time would be hard to tell.

Q. Well, we will assume a certain time. Does it take any longer time when the river is high than when the river is low?

A. Does it take any longer time when the river is high?

Q. Than when it is low, for the processes of fermentation and purification to take place?

A. It may and it may not, because the overflow from the high stage may be so frequent, you understand, and the progress of the sewage may be so impeded that it might take
2583 a longer time, and it might be the reverse for a river of such a length, for such a long distance, with such an immense number of bends and curves, it would be almost difficult to answer that question, to say Yes. I understand it now, Mr. Todd.

Q. The time would be nearer together, that it would require for the purification, than would be the element known as the distance that the stream might run, wouldn't it?

A. I couldn't say so because the distance is too long; it is impossible to draw any such deduction from such a river so peculiar as that river is in its course between Kansas City and St. Louis.

Q. Is the Missouri River a peculiar river?

A. Yes sir.

Q. Kind of like God's chosen people.

A. Not exactly, but it has a big waterway. The largest waterway in this country, very much neglected in regard to regulation and in regard to dams, etc.

Q. You have stated that once before, doctor.

A. Yes sir.

Q. Do you know how far above Bellefontaine the river purifies itself of the sewage of Kansas City?

A. I cannot tell.

Q. Does the figure that you have given that 60 per cent of the sewage of Kansas City empties into the Missouri
2584 River, convey to your mind any idea of the volume of the sewage that enters that river?

A. Calculations could be made to that effect.

Q. Have you in mind now any idea of the volume of the sewage?

A. Well, as I say, it could be calculated by comparing it with the water supply of Kansas City as is done in a great many other cities, and then calculated on sixty per cent of that figure.

Q. Does that 60 per cent include the sewage from the packing houses and stock yards of Kansas City, do you know?

A. Yes, the sewage out-fall into the river as estimated by the city engineer and given to me personally.

MR. WOERNER: Do you know whether that includes the packing houses, or is that in the other 40 per cent?

A. Yes, it included the sewage of Kansas City.

Q. You said sixty per cent of it?

A. Sixty per cent of the population.

MR. TODD: Repeat my question.

(Question repeated)

A. Mr. Todd, I will withdraw that last answer.

Q. Do you know of your own knowledge anything about the sewage of Kansas City?

A. Yes sir.

2585 Q. State what you know about the sewage of Kansas City?

A. I know it from the official statement of the city engineer of Kansas City, made to me in December, 1902, that sixty per cent of the population of Kansas City, Missouri, the sewage of sixty per cent of the population drains directly into the Missouri River.

Q. Are there any stock yards in Kansas City, doctor?

A. I couldn't tell from my own observation.

Q. If there are any, do you know whether the sewage from the cattle in the stock yards is included in the sixty per cent of population?

A. Well that, I have no information about.

Q. Do you know where the slaughter houses in Kansas City, Missouri are located?

A. I don't know of any being located in Kansas City Missouri, because my understanding is that they are located in Kansas City, Kansas.

Q. Do you know whether the sewage from the slaughter-houses in Kansas City, Kansas, drains into the Missouri River or not?

A. I don't recollect at this moment; I really cannot remember.

Q. Doctor, do you know where Kansas City, Kansas is located?

2586 A. Yes sir.

Q. How far is that from Kansas City, Missouri?

A. Why, it is right across the Kaw River.

Q. Assuming that the slaughter houses and packing houses are located at Kansas City, Kansas, on the Kaw River, and that these packing houses, their sewage is emptied into the Kaw River; would that offer any explanation as to the chlorines that are found in the Kaw River?

A. The explanation can easily be given by the fact that the samples taken from the Kaw River were taken way above Kansas City, Kansas, so that no sewage from Kansas City, Kansas, could come into consideration there.

Q. The sewage of Kansas City, Kansas?

A. I understand it is Argentine, Kansas where the Kaw river samples were taken.

Q. It empties into the Missouri or into the Kaw River and ultimately gets into the Missouri River below the confluence of the Kaw with the Missouri, doesen't it?

A. Yes, if it is discharged into that river.

Q. And the sewage of Kansas City enters the Missouri at Kansas City, doesn't it?

A. Sixty per cent of the sewage.

Q. Doctor have you any personal knowledge of how much sewage enters at Kansas City, except what you have been told?

2587 A. Well, that is information I have from the city engineer of Kansas City, who ought to know.

Q. Do you know to what extent he has investigated the sewage question at Kansas City?

A. Yes, he told me that he had investigated it for years and is thoroughly familiar with the conditions.

Q. You have no knowledge of the sewage conditions there, except as were told to you by the city engineer, have you?

A. No sir, that is all.

A. And as to whether his statement of 60 per cent of the population is true or false, true or incorrect, you have no means of knowing, have you?

A. He made the impression upon me of being a trustworthy man.

Q. I am not asking you to pass upon his credibility. Have you personally verified any statement that he made to you?

A. No sir, I have not.

Q. As to what the amount is of 60 per cent of the population, you have no idea, have you?

A. Well now, I took a few notes at that time and I would have to look up those notes to answer that question.

Q. 'Did that 60 per cent include the manufacturing districts of Kansas City, or did it exclude the manufacturing districts of Kansas City?

2588 A. You mean now, Kansas City, Missouri?

Q. Yes, Missouri?

A. Well that I cannot remember just now. We had quite a long conference on the subject and I took notes of the most important facts, but I haven't got those notes with me at this moment.

WILLIAM C. TEICHMANN.

Adjourned until 10:00 a. m. Thursday, April 2nd, 1903.

2589 Southern Hotel, St. Louis, Missouri, 10:00 A. M., Thursday, April 2nd, 1903.

Continuation pursuant to adjournment. Present the Commissioner and the same counsel as before.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for further cross-examination by Mr .Todd and testified as follows:—

Q. Doctor, in your analyses of the waters at Bellefontaine, was the presence of albuminiod ammonia and free ammonia evidence of pollution in the waters at that point?

A. Yes sir, that is, if the free and albuminoid ammonias were high.

Q. Were they high?

A. Well, they varied considerably. Sometimes the albuminoid ammonia would be what I would consider quite high, and the free ammonia would be low at that time, and then again the free ammonia would be a little higher, and the albuminoid ammonia would be lower.

Q. How long, doctor, does it take nitrites by the process of oxidation, to become nitrates?

A. It would be impossible to tell as to this process tak-
2590 ing place in running rivers, but from samples of water
that have been collected and left standing in laboratories, and from day to day the water analyzed for nitrites, and nitrates, some chemists have estimated the number of days it would take for the oxidation of the nitrites to nitrates in that bottle of water owing to the evident presence of aerobic bacteria in the water.

Q. Would the time depend upon the number of the bacteria in that water?

A. Evidently, because the aerobic bacteria are the ones that produce this oxidation of the nitrites to the nitrates.

Q. If the waters contained large quantities of bacteria such as you have described, the time for changing the nitrites to nitrates would be lessened, would it not?

A. Yes sir.

Q. Do you know of any rule that would apply to conditions such as are contained in the question just answered?

A. No sir, not in regard to the running waters, only in regard to laboratory experiments.

Q. Well, I mean in laboratory experiments, doctor.

A. Well, these laboratory experiments simply in each case would establish the fact that the nitrites found present in the respective samples of water on the first day, disappear after a number of days.

2591 Q. About how many days?

A. (Continuing)—and the nitrites increase show that they had been converted into nitrates.

Q. How many days would that take, doctor?

A. Well, that would depend very much upon the amount of nitrites present and the quantity of aerobic bacteria performing this oxidation process.

Q. Suppose that there would be a great number of aerobic bacteria present in the water and the nitrites were not in a large quantity, how long would it take?

A. This process would be a very rapid one. It might take 24 hours and it might take 48 hours for a—well a small amount of nitrites to disappear.

Q. If the aerobic bacteria were present in the running waters in great numbers, that would have a tendency to decrease the nitrites even in the water, would it not?

A. Yes sir.

Q. And when that water is placed in the laboratory, the action would be a great deal faster on that same water than it would while in the running stream, would it not?

A. Well, that could not be determined, because you can't bring in comparative results of the time required for oxidation action in the running water itself. You only have the
2592 laboratory samples there and have no river samples to compare with them.

Q. But by analogy, bacteria will work faster in still water than in running water, will they not?

A. Well the bacteria—it depends very much upon the number of bacteria present.

Q. Assuming the same number to a cubic volume of water in a running stream and in a vessel, would not the bacteria have better opportunities for working in still water than in running water that is constantly changing?

A. Well that would again depend upon the weather conditions at that time, for instance—

Q. Well, under the same conditions of temperature?

A. The same conditions of temperature—well they would be much more active during the warmer season of the year than they would in the winter season.

Q. Well I am speaking of the samples of water now in the laborotory—the laboratory tests?

A. There may be cases where that may be true.

Q. Well, do you know, doctor? Have you any definite information on the subject as to whether the an-aerobic bacteria—

A. Now you mean aerobic or an-aerobic?

Q. Aerobic bacteria in a given quantity of water in a given amount of nitrites, in a running water and in the
2593 water that is in the vessel, whether the bacteria will convert the nitrites to nitrates any faster in the bottle than it would in the river under the same temperature?

A. Well that would depend very much upon the quantity of dissolved oxygen present in the sample of water closed up in the bottle, because when that supply of dissolved oxygen is exhausted,—which dissolved oxygen is necessary for the life of the aerobic bacteria, and which dissolved oxygen is apparently used to oxidize the nitrites to nitrates by adding one atom of oxygen to the nitrites, and converting it into nitrates, when that supply is exhausted, why then the action ceases, and the aerobic bacteria would probably die, because they need the oxygen to live.

Q. In the laboratory test do you cut off the supply of the oxygen?

A. Well, the question is this, that it is the oxygen that is dissolved in the water which furnishes the supply for this bacterial action and bacterial life—

Q. Does that same condition obtain in the waters of the river?

A. Yes sir.

Q. So that if a sample of water was taken out of the river today, would the nitrites in that sample operate more speedily. I mean would the bacteria in that sample operate more speedily than they would in the river under similar conditions? 2594

A. Well, if the supply of dissolved oxygen would be larger in the sample in the bottle, in comparison with an equal quantity of water in the river and if the number of bacteria—aerobic bacteria would be larger in the bottle, of course the action would be much more rapid.

Q. Can you tell whether in the sample of water taken out of the river there would be any more bacteria in the sample than in the water of the river?

A. No, at the time when the sample would be taken and very soon afterwards naturally the proportionate quantity would be the same because the sample was taken from that river, but there are very rapid changes going on in the sample of water immediately after the collection, and—

Q. What changes are those, doctor?

A. Well, the aerobic bacteria will continue their action of oxidation constantly, that is, from the moment that the sample is taken and the sample as it gets to the laboratory.

Q. On the nitrites?

A. Yes sir. That is one of the reasons why the nitrites are first tested in the sample of water, because of the rapid oxidation.

Q. Does the oxidation process go on as swiftly for albu-
2595 minoid ammonia as for the nitrites?

A. No sir, it does not. That is—

Q. Does it go on as swiftly for the free ammonia as for the nitrites?

A. No sir, not as swiftly, but it does go on.

Q. Does the presence of clay or silt retard or facilitate the action of microbes upon nitrites?

A. Well this clay usually contains a large number of bacteria that perform this nitrifying process. They are found in the soil and this soil is washed into the rivers, and would get into the sample of water collected, and the bacterial action there by the laws of nature in oxidizing the nitrites would be materially facilitated by the nitrifying bacteria or these oxidizing aerobic bacteria in the soil there.

Q. So that the presence of clay and silt is evidence of a greater number of these bacteria that possess the nitrifying effect upon the nitrites?

A. Yes sir, the conclusion is justifiable that they are there in great numbers.

Q. Now doctor, the waters of the Missouri River—how do the waters of the Missouri River compare with the waters of
the Mississippi as to the presence of these bacteria, an-
2596 aerobic I believe you call them, wasn't it?

A. No, aerobic; those that live in the presence of oxygen.

Q. Aerobic bacteria.

A. The anaerobic bacteria, that is—

A. Well I have got it now. How do the waters of the Missouri compare with the waters of the Mississippi in the presence of aerobic bacteria?

A. Well the larger amount of sediment usually found,—not always, but,—well, prevailingly, found during the year in the Missouri River as compared with the Mississippi River would show that there are more nitrifying or so-called oxidizing aerobic bacteria in the Missouri River water and that of course would accelerate the oxidizing action in that water,—in the Missouri River water as compared with the Mississippi.

Q. Now the aerobic bacteria oxidizes the nitrates in water.

A. The nitrites.

Q. The nitrites in water much more rapidly than they do the albuminoid ammonia or the free ammonia, do they?

A. Well the analytical results by which this question was investigated from laboratory experiments shows throughout,—these various investigations of the kind have been made for instance by Mason, of Troy, New York—they show in the analytical results of water of one sample collected day after day from the same original sample that the changing of the am-
2597 monia into nitrites was slow, that is the reduction per day
of ammonia in quantity as estimated by analyses was very small, whereas, the reduction of nitrites was large and that small amounts of nitrites would as I said, disappear in a period of from 24 hours to 48 hours.

Q. Now when the samples were taken at Fort Bellefontaine, how long a period intervened between the taking of those samples and the analysis for nitrites?

A. These samples were collected about ten or eleven o'clock in the morning; they arrived at the laboratory regularly at half past one o'clock, or two o'clock if the train would be late. The nitrites were determined immediately upon the arrival ot the samples so that the period intervening between the time of the collection and the time of the analysis for nitrites constituted from three to four hours.

Q. During those three or four hours, could you tell to what extent the oxidation of the nitrites had taken place by the action of the aerobic bacteria?

A. No sir, because that would have necessitated comparative tests on the spot, or rather at the place of the collection, and then comparative tests very soon afterwards.

Q. So no test was made at the place of collection, was there?

A. Not for nitrites.

2598 Q. Was any test made that would enable you to speak
definitely as to how long it would take the nitrites in the Missouri water at the time of collection to be converted to nitrates?

A. You mean to nitrites or nitrates?

Q. The nitrites to be converted to nitrates?

A. The nitrates, oh yes. No sir, the samples were packed in ice and the low temperature would have retarded the oxidation action to such an extent that I would consider the changes that might have taken place in that direction during those few hours so insignificant that they could be overlooked in the result.

Q. But you made no effort to definitely ascertain whether that conclusion was justified or not, did you?

A. Well, I base this conclusion on the fact that if this water is kept at low temperatures this oxidation process is very slow and so slow that it would not affect materially the analytical result.

Q. Did you make any test between waters taken at the same time,—one sample kept at a low temperature and the other kept at the normal temperature of the weather at the time of taking, to ascertain what changes if any, took place between the time of taking and the time of analysis in order to ascertain the effect of temperature upon the waters? 2599

A. Not for samples collected at Fort Bellefontaine.

Q. Then if you made no test or analysis to determine that fact the statement that no changes of any appreciable amount took place because of the fact that the samples were packed in ice, is a mere assumption, is it not?

A. As applied to this particular case it is an assumption, but based upon comparative investigations of samples from other points—

Q. Under similar conditions?

A. Well, I won't say that they were absolutely similar, but conditions corresponding in a general way.

Q. With the presence of clay and silt such as is found in the Missouri River?

A. Well I don't recollect at this instant, whether those samples upon which these experiments were made contained as much sediment as the samples usually contain that come from Fort Bellefontaine.

Q. Did the samples that you speak of as giving you a criterion to base your judgment upon, have as many aerobic bacteria in them as is found in the waters of the Missouri at Fort Bellefontaine?

A. Well, that I could not tell because the quantities of these bacteria cannot be estimated.

2600 Q. Cannot a bacteriologist estimate the quantity of those bacteria?

A. No sir, not to my knowledge. That is, the absolute distinction between the quantities of these bacteria from those rivers to my knowledge, has not been made, but approximate estimates of the amounts have been made from septic tanks as to the total approximate number of an-aerobic bacteria and aerobic bacteria present in that tank, but to my knowledge no such experiments have been made as regards this water here.

Q. Has bacterial science developed to such an extent as to enable the bacteriologist to ascertain accurately the number of these bacteria in a given sample of water?

A. Not what I would call a result of absolutely correct figures. They are approximations which are derived from the method of bacterial counts in large numbers.

Q. Do you know whether any such investigation for the purpose of ascertaining the quantity of bacteria known as aerobic was made of the waters of the Missouri River at Bellefontaine, which you examined?

A. No sir.

Q. Can you state, doctor, as a positive fact, that the low nitrites which you found in the waters of the Missouri at Fort Bellefontaine are not attributable directly to the action of these bacteria from the time of the taking of the sample
2601 up to the time of the analysis?

A. If such a reduction of nitrites to nitrates, or rather oxidation, to be absolutely scientific, if oxidation of nitrites to nitrates took place in those samples while they were in transit from the station at Fort Bellefontaine to the laboratory it would be so inappreciable that it could be disregarded because of the fact that the samples were packed in ice and kept at a very low temperature from the time that they were collected until the time that the chemist would take the sample—open the bottle and make his nitrite tests.

Q. How do you know that, doctor, as a scientific fact, as applicable to the waters of the Missouri?

A. Because the comparative tests that I have made on several occasions of the samples that were packed in ice and sent from certain points to St. Louis, and samples taken from those same places that were not packed in ice and taken to St. Louis and analyzed, and samples that were analyzed for nitrites very soon,—probably ten minutes after they were taken from the place of collection and analyzed on a boat. From comparative tests that I have thus made there I have come to the conclusion that the oxidation of nitrites is inappreciable for six hours at times, and at other times at eight hours, if the samples were properly packed in ice.

2602 Q. Were those samples of water that you made that experiment upon, identical with the waters of the Missouri?

A. No, sir; they were Mississippi River samples.

Q. Did the water contain the same number of aerobic bacteria that the waters of the Missouri contain?

A. There were no bacteriological approximations made on the number of aerobic bacteria from those samples.

Q. Then if the process of oxidation upon nitrates depends upon the quantity of aerobic bacteria and you made no investigations to ascertain that fact, how can you assert that oxidation did not take place between the time of taking the samples in the Missouri River at Fort Bellefontaine, and the analysis in the laboratory of the city chemist?

A. Because if samples taken at a point and packed in ice, and not tested for nitrites until eight hours after the samples were collected, and they show no appreciable difference in the quantity of nitrites as compared with the sample analyzed practically on the spot of collection—I don't say spot of collection because the samples were taken from the Mississippi River, and on the harbor boat there were appliances enabling us to make direct tests for nitrites, right on the spot there, I say, if there was no appreciable difference there in the nitrite results, a sample of water packed in ice, collected from Fort Belle-
2603 fontaine and analyzed three hours after its collection
would not show much or any appreciable change in the nitrite results, because the nitrite results did not show it in the other sample for such a long distance. Now, even if the number of aerobic bacteria would have been considerably less—grant that—that they were less in the sample collected from the Mississippi River and not analyzed until eight hours afterwards, it would stand to reason that even the lesser number would pro-

duce the same result within a period of eight hours, because it is a much longer period than three hours, and the changes of the nitrites to nitrates will progress faster according to the time until eventually the supply of dissolved oxygen is exhausted, when their action ceases.

Q. Doesn't the test that you have just given only prove the absence of aerobic bacteria in the waters that you made the test with, and does not warrant the conclusion that you draw from it?

A. No, sir.

Q. If you were going to make the test to find out whether there was no aerobic bacteria operating upon the nitrites, wouldn't the test that you have just indicated demonstrate that fact?

A. I said that the changes were inappreciable. There must be some aerobic bacteria—must have been present in those samples taken from the Mississippi River. 2604

Q. And the test that you made showed the presence of a very small quantity of aerobic bacteria because of the fact that the nitrites were not appreciably oxidized, doesn't it?

A. That conclusion would only follow if the sediment in that water taken from the Mississippi River was very small, but I have not got the data at hand now, I don't remember exactly how much less a sediment or how much less a suspended matter in the form of sediment was present in those Mississippi River samples on that day, or whether there may have been more present than in samples of the Missouri River; although I will say that at times the Missouri River has more sediment than the Mississippi River at any time.

Q. Can you, doctor, institute a proper comparison between the waters of the Missouri and the waters of the Mississippi?

A. Yes, sir.

Q. And can you draw an accurate conclusion as to the effect of aerobic bacteria upon nitrites in the Missouri from an investigaton in the Mississippi?

A. There are—

Q. Now answer my question, doctor. I am going to insist upon a definite answer and an explanation afterwards.

A. Yes, sir, I can.

2605 Q. You can?

A. Yes, sir.

Q. You made no investigation in any of your analyses for the presence of aerobic bacteria in the waters of the Mississippi, did you?

A. No, sir.

Q. The oxidation of nitrites depends upon the presence of these bacteria, does it not?

A. Yes, sir.

Q. If this bacterium is present in large quantities, oxidation will be facilitated, will it not?

A. Provided, that there is also a large quantity of dissolved oxygen present in that water.

Q. Is there any reason why there would not be as large a quantity of dissolved oxygen in the waters of the Missouri as in the waters of the Mississippi?

A. There may at times be more disolved oxygen found in one river than there is in the other—either one.

Q. Did you make an examination of the waters of the Mississippi River to find out whether the quantity of dissolved oxygen was the same, more or less, in the Missouri than in the Mississippi?

A. Yes, sir.

2606 Q. In connection with the analyses of these samples?

A. I had such tests made by my assistants.

Q. Did you take that into consideration in arriving at the conclusion as to the oxidation of nitrites in the Missouri River from the time of taking, to the laboratory?

A. I examined the analytical—

Q. No. Did you take it into consideration, doctor, in giving your opinion?

A. I did.

Q. What was the difference between the oxidation in the Missouri and the oxidation in the Mississippi at the time these samples were taken?

A. Now, I will have to look up the data; it is some time ago that those data were prepared.

Q. Was it more or less in the Missouri than in the Mississippi?

A. I will have to look up the data. I haven't it at hand here, though.

Q. Was it the same in the Missouri as in the Mississippi?

A. Well, now, there are only a few occasions when those tests were made, and I really do not recollect the exact figures at this moment, but I have them ready.

Q. Was the difference marked enough to change the
2607 character of the waters of the Missouri from the waters
of the Mississippi?

A. That I am not prepared to say until I have looked at the data again; I haven't got them at hand, and haven't looked at them for some time.

Q. Then, doctor, if you made no comparison between the aerobic bacteria of the Missouri and the aerobic bacteria of the Mississippi and the clay and silt of the Missouri facilitates oxidation of nitrites, can you state as a positive ascertained scientific fact that the nitrites in the Missouri River at the time of taking the sample, do not become oxidized by the actions of these microbes to a large extent from the time of the taking of the waters to the time that they reached the laboratory?

A. Yes, sir.

Q. You can?

A. Yes, sir.

Q. What is the time?

A. The difference would be inappreciable, because—

Q. How do you arrive at that time, doctor, as to the particular waters of the Missouri River in the absence of having made any test upon that water?

A. Because I consider three hours for the transfer of those
samples, provided, that the samples were packed in ice
2608 and kept on ice from the time of their collection to the
time of their analysis, I consider any change that may
take place so inappreciable that it can be disregarded in the chemical results in drawing conclusions from the chemical results of the analyses of that sample at the laboratory.

Q. Can you give me any reason based upon your scientific examinations of the waters of the Missouri, why one hour would not be more nearly the exact time than three for ascertaining that conclusion?

A. I am convinced that three hours wouldn't make a material difference so as to in any way affect the result of the analyses and affect the conclusions to be drawn from the result.

Q. Do you know what the difference would be in nitrites upon the waters in the Missouri River analyzed at the time of taking and analyzed four hours afterwards at the laboratory?

A. I don't know at this moment.

Q. Have you ever made an examinaton of the waters of the Missouri River at Fort Bellefontaine at the time they were taken out of the river?

A. No, sir, not at Fort Bellefontaine.

Q. That's what I am speaking about.

A. I have taken samples and analyzed them at the mouth of the Missouri which I had just recollected.

2609 Q. Now, as you have made no examination, doctor, of the waters at Fort Bellefontaine at the time they were taken out of the river to compare with the samples analyzed three or four hours afterwards—are you able to state as a scientific fact what the effect of the aerobic bacteria upon that water is from the time of leaving the stream until the time it gets to the laboratory?

A. The conclusion would be justified—

Q. I am not asking for the conclusion, doctor?

A. The effect is unappreciable.

Q. (Question repeated.)

A. Yes, sir.

Q. You are?

A. Yes, sir.

Q. Is that result attained by the analyses of the waters of the Missouri at Fort Bellefontaine?

A. You mean the analyses of the samples taken at Fort Bellefontaine in the laboratory?

Q. No, at Fort Bellefontaine?

A. You mean the analyses made at the point of collection?

Q. Yes?

A. No, sir.

2610 Q. Is the conclusion arrived at by the analyses of waters in every way similar to the waters of the Missouri River at Fort Bellefontaine?

A. It is a conclusion arrived at from a number of analyses of waters made sufficient to justify the conclusion that the effect of oxidation in transit between Fort Bellefontaine and the laboratory would be unappreciable.

MR. TODD: I move to strike out the answer and ask for a specific answer to my question.

(Question repeated.)

A. I cannot tell at this moment because I haven't got the data at hand upon which I base these conclusions, for comparison, to say whether the samples were similar in chemical character. It may have been that the conditions prevailing at Fort Bellefontaine—I cannot tell that.

Q. You cannot tell?

A. No, sir.

Q. Doctor, can you institute a comparison between similar waters?

A. Yes, sir.

Q. Can things of dissimilarity be compared?

A. Well, now—

Q. As an example, can you compare a horse and a cow?

A. There is a tautology in that question.

2611 Q. Can you, in chemistry, compare or draw a comparison between dissimilar quantities in chemistry any more than you can draw a comparison between dissimilar animals?

A. Well, I won't say in regard to animals, but in regard to chemistry I would answer that question yes.

Q. Can you institute a comparison between the waters of the Missouri River and the waters of the Mississippi as far as the oxidation of nitrites are concerned in the absence of any knowledge upon the number or quantity of the aerobic bacteria in that water?

A. Yes, sir.

Q. It can be done, can it?

A. Yes, sir.

Q. Does the quantity of aerobic bacteria have anything to do with the comparison?

A. Not directly.

Q. Does it indirectly?

A. As far as—

Q. Answer yes or no. You stated not directly. Now does it indirectly?

(Question repeated), of the waters of the Missouri, and the waters of the Mississippi?

A. A comparison taken from what standpoint?

Q. For the oxidation of nitrites?

2612 A. No, sir.

Q. Then, if the quantity of bacteria has nothing to do with the oxidation of nitrites directly or indirectly, what effect upon the nitrites do the bacteria have?

A. It is a question of cause and effect. The effect is established by analytical results. "What is that water," "what kind of water is it?" Then if the causes of the condition found in that water are taken into consideration; the causes, for instance, why the low nitrites are found, or the high nitrates, then in considering the cause of that condition found as the effect, the action of the aerobic bacteria would come into consideration as an explanation for the cause of that effect.

Q. The effect in water analyses is just as essential as the cause, isn't it?

A. Certainly, the effect is based upon the cause.

Q. And the cause plays a considerable part in the analyses, doesn't it?

A. No, sir. You look for the effect only. You want to establish the character of that water; you want to say "What kind of water is this?" You say, "What is the analytical result?" That is the effect.

Q. You say in your analyses you look for cause, didn't you, throughout this investigation?

2613 A. I looked for causes so far as the water is concerned, on the route between Chicago and St. Louis.

Q. But as far as the Missouri River is concerned, you didn't look for causes?

A. No, sir. You mean Fort Bellefontaine samples?

Q. Fort Bellefontaine?

A. As regards Fort Bellefontaine samples I only looked for the condition of the water at Fort Bellenfontaine.

Q. And didn't look for the causes?

A. No, sir.

Q. And that is the reason in the analyses of the waters of the Missouri River that you eliminated the consideration of the sewage pollution coming from Kansas City, Missouri, and Kansas City, Kansas, is it because you didn't care to—because you went at the effect? Answer that question, doctor, yes or no?

A. The effect would be the only fact that came into consideration in this investigation.

Q. And it doesn't make any difference whether the causes which established that effect was sewage contamination from Kansas City, Missouri, and the stock yards pollution from Kansas City, Kansas. All you were looking at was the effect at Fort Bellefontaine, is that right?

2614 A. Since for certain months I established the fact, in certain periods of the year, I established the fact that the water found at Bellefontaine was chemically good and potable water, and the conclusions that I have drawn from the conditions of that water as I found it were based upon the conditions prevailing during that period, a consideration of any cause there, was immaterial, unnecessary, because all that was necessary to establish was the sanitary character of the water at Fort Bellefontaine.

MR. TODD: I move to strike out the answer and ask to have a specific answer to my question.

(Question repeated.)

A. Well, I don't admit sewage pollution at Fort Bellefontaine from Kansas City or the stock yards.

MR. TODD: I move to strike out the answer and ask to have a specific answer to my question.

A. Well, the question is based—

Q. My question is clear cut and put in decisive language, doctor, and I would like to have you answer it, based on your testimony.

A. It involves the existence of sewage pollution at Fort Bellefontaine and Kansas City, which I do not admit.

MR. TODD: I move to strike out the answer and ask to have a specific answer to my question.

2615 Q. (Question repeated.)

A. It would make a difference if I establish pollution of the water as due to sewage from Kansas City and refuse from the stock yards because that would involve a question that required consideraion as to the point of a pollution of streams.

Q. Do you consider that as an answer to my question, doctor?

A. As I say, I cannot answer the question in any other way.

Q. Now, do you consider that last answer an answer to my question?

A. Yes, sir.

Q. Were you looking after the causes in your analyses of the waters at Fort Bellefontaine?

MR. WOERNER: The causes of what?

MR. TODD: Or for simply the effects, whatever those effects might be?

A. During that period—

Q. Answer my question, doctor?

A. I did partly during that period when the investigation showed pollution of the Missouri River at Fort Bellefontaine, I considered it my duty to ascertain what this pollution may be ascribed to.

2616 Q. Then your answer to my previous question that you were looking for effect and didn't take into consideraion the causes, you wish to modify, do you?

A. That is to be applied to that period when I found that water good and potable; then it was unnecessary to look for any cause, but during that period of the investigation when I would find the Missouri River water polluted I made an effort to ascertain the causes of that pollution.

Q. Then when you stated that in your investigations at Fort Bellefontaine you were only looking for the effects and had nothing to do with the cause, you didn't exactly state your condition, did you?

A. I understood the question to apply to that period of the investigation which was discussed when we found the water good and potable.

Q. So, then, as long as you found the water good, you didn't look for any causes?

A. No, sir.

Q. And as you found the water good nearly all the year there was no necessity for looking for any causes, was there?

MR. WOERNER: We object to the question, because it is impossible to tell what causes are referred to in the question. What is meant by the word "causes?" I am sure I don't understand it.

2617 MR. TODD: The causes of purification.

A. When you speak of causes—

Q. I want this all in the record. I am willing once in a while to let it go, but I want to have it all in the record, doctor?

A. All right.

Q. Now, when you found the water pure or good, that is the word you used—at Fort Bellefontaine, you didn't look for the causes that created that good condition of the waters, did you?

A. No, sir.

Q. You were mindful all the time in your investigation that the sewage of Kansas City, Missouri, and Kansas City, Kansas, and the other towns located upon the Missouri River, was emptying into the Missouri River, were you not?

A. Yes, sir.

Q. And as long as you found the water good, you didn't look for the causes that purified the water from the sewage contaminations of the cities above, did you?

A. No, sir.

Q. Are you able to state what made the waters good with the knowledge that there was sewage pollution at Kansas City and at other points?

A. Nobody could state that—that is impossible.

2618 Q. Then that is a matter outside of the realm of scientific research, is it?

A. No, sir.

Q. Then if nobody could tell what caused that, can you name anybody who could?

A. No, sir.

Q. Then, if nobody knows what causes, scientific men have not been able up to the present time to give an explanation of that condition of purification, have they?

A. They can give an explanation from studying the general conditions prevailing in the Missouri River between Kansas City and Bellefontaine.

Q. Then, what did you mean, doctor, by stating that no one could tell the causes of purification?

A. Because scientific researches have not been made to the extent of analytical survey of the entire route from innumerable points between Kansas City and St. Louis, and therefore an opinion may be formed on the queston of what becomes of the Kansas City sewage, would be based upon the general conditions prevailing in that river between Kansas City and St. Louis as described in my testimony previously, from which general conclusions could be drawn as to what may become of the Kansas City sewage.

Q. It is problematical, is it?

2619 A. Yes, sir.

Q. No scientifically ascertained results at present have been achieved?

A. It is problematical, yes, sir.

Q. But it isn't problematical what becomes of the sewage of Chicago, is it, doctor?

A. The conditions—

Q. Answer the question, doctor?

A. The Chicago sewage is entirely different.

Q. Has the light of scientific truth shone more clearly upon the chemical and bacteriological mind, in regard to the Chicago sewage than that of the Kansas City sewage?

A. The conditions of the two rivers are so materially different. The quantity of sewage coming from Kansas City being discharged into the river is so materially different from the sewage being discharged from Chicago into the Desplaines River, the conditions of the Desplaines River and the Illinois River vary so much from the conditions prevailing in the Missouri River. The distance between Chicago and St. Louis for the sewage to run, 357 miles, and the distance from Kansas City to St. Louis, 403 miles.

Q. Making how many miles difference?

A. Forty-six miles.

2620 Q. Doctor, have you any personal knowledge of the quantity of sewage from Kansas City that empties into the Missouri River?

A. I haven't got the data at hand.

Q. I mean personal knowledge.

A. I have calculated the amount of sewage discharging into the Missouri River on the same principle, and at the same ratio that the sewage from Chicago is calculated on.

Q. We will get at the sewage of Chicago before we get through, doctor. I want to know if you have got any personal knowledge of the amount of sewage from Kansas City, Missouri, and Kansas City, Kansas, as to the quantity, that enters the Missouri River?

A. Yes, sir.

Q. Have you been there and investigated it?

A. I have been there.

Q. Have you seen where the sewage empties into the Missouri River?

A. That is not necessary.

Q. I am not asking you what is necessary. Have you seen it?

A. No, sir.

Q. Do you know how much sewage enters the Missouri River from the Kansas City stock yards and the packing houses?

A. I formed a computation upon recognized tables that are usually used.

MR. TODD: I move to strike out the answer as not responsive. 2621

Q. Do you know? You can answer yes or no.

MR. JEFFRIES: I submit the witness has stated how he knows.

Q. MR. TODD: If he has answered the question—I submit to counsel that is the proper way to answer a question, yes or no. It is a question if he knows.

A. I don't know at this moment, because I haven't got the data at hand upon which I can base the customary calculations.

Q. Have you ever been in Kansas City, Kansas, where the slaughterhouses and packing pens and cattle-sheds are located?

A. I have been in Kansas City, Missouri.

Q. I am asking you about Kansas City, Kansas.

A. Not in Kansas City, Kansas.

Q. Do you know anything about the quantity of sewage from those slaughterhouses in Kansas City, Kansas?

A. I did know it, and I can re-calculate it again if I have the tables here.

Q. Based upon your personal knowledge?

A. I consider that personal knowledge.

Q. Do you consider what somebody else has told you as being personal knewledge?

A. No, sir; but personal investigation.

Q. I am not asking about personal investigation. I want to know about your personal knowledge.

2622 A. I consider that personal knowledge.

Q. You consider, then, what somebody else has told you as personal knowledge?

A. This is not what somebody else has told me.

This is my own personal information.

Q. Do you know how much sewage comes from the slaughterhouses?

A. That is impossible to know unless one examines the respecitive slaughterhouses and makes personal estimations and personal investigations on the spot.

Q. That you have not done, have you?

A. That is not customarily done.

Q. I am not asking you about the custom; I want to know what you have done?

A. I haven't done it, no, sir.

Q. Then you don't know as a matter of fact what the quantity of sewage that enters the Missouri River at Kansas City, Kansas, or Kansas City, Missouri, do you?

A. I can ascertain it by customary computation.

Q. Have you in your mind now, doctor, any definite amount of sewage that enters the Missouri River at those points?

A. Not at this moment. This data I have prepared some time ago. I haven't got them at hand now. I cannot recall them at this moment; it is impossible to do that.

2623 Q. In giving your answers to questions that have preceded, have you taken into consideration by any definite assumption the amount of sewage entering the Missouri River from those two points, based upon personal knowledge?

A. That depends upon what you consider personal knowledge.

Q. I mean personal knowledge that everybody considers personal knowledge. Knowledge that you have obtained by your personal observation?

A. Yes, sir.

Q. And yet you cannot state that you have a personal knowledge of the sewage of Kansas City, Missouri, as you have never been in the town?

A. This personal knowledge is obtained in the customary way by customary calculation.

Q. Do you know the size of the slaughterhouses in Kansas City, Missouri?

A. No, sir.

Q. Do you know the number of cattle that are slaughtered there per day?

A. I couldn't tell you at this moment.

Q. I mean Kansas City, Kansas.

A. I had those data but I haven't got them at hand and I haven't got them in my memory at this moment.

2624 Q. Have you ever figured it out in tons, the amount of sewage that enters the Missouri at Kansas City, Kansas, and Kansas City, Missouri?

A. I have estimated it in volume, yes, sir.

Q. Have you estimated it as to Kansas City, Kansas?

A. Yes, sir.

Q. What is the purpose of making that estimation, doctor?

A. The purpose of that estimation was to ascertain how much sewage enters the Missouri River, in accordance with the customary estimation, from Kansas City, Missouri, and Kansas City, Kansas.

Q. What did you want to know that for, doctor?

A. To find out how much sewage these cities discharged into the Missouri River.

Q. After you found that out, what use did you make of it?

A. Well, I studied the conditions of the Missouri River and I utilized the data in the customary way such conditions are studied.

Q. When you made your analyses below Kansas City, Missouri, for the ascertaining of chlorine in the Missouri River, why didn't you take into consideration the volume of sewage that you have testified to having at one time estimated in considering the chlorine test at that point?

A. I didn't consider the chlorines; I considered the sewage
2625 as such.

Q. My question is, why didn't you take into consideration in ascertaining the source that chlorine came from, the sewage of Kansas City, Kansas, and Kansas City, Missouri, when you made the test below Kansas City?

A. Because it is difficult to estimate from the volume of sewage discharged into that river the quantity of chlorine.

Q. Is it any more difficult, doctor, to estimate the quantity of chlorine below Kansas City, that enters that river from the sewage of Kansas City, Missouri, and Kansas City, Kansas, than it is to estimate the amount of chlorine that comes from the Kaw river population of Kansas City?

A. That is a different proposition. The chlorine in the Kansas or Kaw River is estimated and analytically by taking a sample right from the river and analyzing it, the quantity of chlorine, to find out how much chlorine is contained in the sewage discharged from the city of Kansas City, is extremely difficult, because there are a number of sewers there and the water has to be taken out of the sewers there and tested, and then you have to approximate, which may not be sufficiently reliable to be used as data, establishing how much chlorine there is in sewage coming from all these sewers.

Q. Was it because of the difficulty in ascertaining those facts that made you eliminate the sewage from Kansas
2626 City, Missouri, and Kansas City, Kansas, in ascertaining the chlorine below Kansas City and attributing it to the Kaw River?

A. I didn't eliminate the sewage of Kansas City in passing an opinion on the chlorines, as compared in the Kaw River and found below Kansas City.

Q. How much of the chlorine that you discovered in your analyses below Kansas City, was attributable to the sewage from Kansas City, Kansas, and Kansas City, Missouri?

A. That is a question which I yesterday answered, that I couldn't tell because I hadn't made investigations as to the quantity of chlorine to be found in the sewage discharge from various out-falls, into the Missouri River, because of the extreme difficulty in ascertaining the amount of chlorine there.

Q. Can you say now from your investigations that 80 per cent. of the chlorines found below Kansas City, is not directly attributable to the sewage from those two places?

A. I couldn't say from any investigation made, but I don't think that it is likely.

Q. Have you an opinion as to what amount of it is attributable to the Kaw River?

A. Well, that depends upon the volume of water in the Missouri River at Kansas City.

Q. What's that?

2627 A. It would vary much; it depends upon the volume of water in the Missouri.

Q. Then taking the chlorine at Bellefontaine can you state how much of that chlorine is attributable to the sewage pollution of the Missouri River from Kansas City, Missouri, and Kansas City, Kansas.

A. When the Missouri River is low at Kansas City, I would attribute a considerable portion of the chlorines found at Bellefontaine to the Kaw River.

MR. TODD: I move to strike out the answer and ask to have a specific answer to my question.

(Question repeated.)

A. I couldn't tell in accurate figures.

Q. Is there anything in connection with the chlorine itself that will enable you to tell whether it is mineral pollution as evidenced by the discharge of the Kaw, or sewage pollution as evidenced by the sewage of Kansas City, Kansas, and Kansas City, Missouri?

A. Yes, sir.

Q. What is it, doctor?

A. As I explained yesterday.

Q. Just explain it today.

A. The fact that the analytical results of the water at
2628 Fort Bellefontaine do not show correspondingly high free
ammonia and chlorines and nitrites together.

Q. Doctor, I suggest you don't understand my question.

MR. WOERNER: Yes he does. He is getting that all right. Go ahead, doctor.

A. (Continuing) And that the nitrites are uniformly low is no justification to ascribe that pollution or rather to ascribe the high chlorines to sewage pollution.

MR. WOERNER: Let him answer that question without interruption. You interrupt him.

MR. TODD: I am satisfied he is not answering the question. I am satisfied he doesn't understand my question.

Q. (Question repeated.) The question is, is there anything in the chlorine itself?

A. No, sir.

Q. Then the only reason that you attribute the presence of chlorine at Bellefontaine to the Kaw River and not to sewage is based upon considerations aside from the chlorine itself?

A. No, sir. Now, I can explain if you want me to.

Q. You have answered my question, doctor, and if you want to explain you may.

MR. JEFFRIES: Go ahead and explain.

A. In determining that question it is necessary to take into consideration the general analytical results as found from
2629 the analyses of the samples at Fort Bellefontaine. If
the chlorine is due to sewage pollution there should be high nitrites; high free ammonias, and high organic matter would show in the results. If the nitrites are low and the free ammonias low, as it usually is in the Missouri River, this high chlorine cannot be attributed to sewage pollution; it must come from mineral matter. It must come from salt.

Q. Then the determination of the sources of the chlorine must be had from outside considerations, aside from the chlorine itself, is that right?

MR. JEFFRIES: The witness answered that very same question an hour ago.

MR. TODD: He answered another question in which the answer to that question is found, but not that question.

THE WITNESS: I don't understand the queston.

Q. (Question repeated.)

A. Yes, in such a case.

Q. And that determination is largely based on low nitrites, high free ammonia—low free ammonia and what else?

A. And low nitrites.

Q. Anything else?

A. And high chlorines.

2630 Q. How about albuminoid ammonia, doctor?

A. I believe I stated that albuminoid ammonia would come into consideration as organic matter.

Q. High or low albuminoid ammonia?

A. Either high or low. If the free ammonia were low and the nitrites were low, that is the most essential point involved there.

Q. Did you find high albuminoid ammonia in the Missouri River?

A. I found at times comparatively high albuminoid ammonia, yes.

Q. Didn't that condition obtain nearly all the year?

A. No, sir.

Q. What part of the year for the albuminoid ammonia?

A. Well, now, to be accurate I would have to refresh my memory from the data there.

Q. Will you make a mental note of that and at two o'clock be prepared to give me in a short answer the period that high albuminoid ammonia was in the water?

A. Yes, sir, I will.

Q. How about the free ammonia, doctor?

A. Well, the free ammonia for the major part of the year is very low; is very low in the Missouri River for the major part of the year.

2631 Q. Do you know how much of the time?

A. The larger part of the year I would consider it low.

Q. And the nitrites are low all the time?

A. Yes, they are either very low or absent entirely.

Q. Now, if the chlorines were attributed to sewage pollution and not to the Kaw river, what conclusion would you arrive at on that hypothesis?

A. Well, conclusion as to what?

Q. As to the potability of the water?

A. In determining the potability of the water, I would take into consideration general analytical results.

Q. Well, assume that the general analytical results show albuminoid ammonia, free ammonia, low nitrites, chlorines in the amount that you found it, but that the chlorines were attributable to sewage pollution, and that there was no river Kaw there?

A. Well, if it would be an established fact that the chlorine was due to sewage pollution, why that water in itself would be unpotable, because of its sewage origin, and if the chlorines were identified as coming from sewage pollution, the presence of the other ingredients going with it would of themselves form a part of that conclusion, because the fact is then established as such, that the chlorine is due to sewage pollution. If that fact is established.

2632 Q. Would the volume of the Kaw River, if its volume was shown to be very small in comparison with the volume of the Missouri River, change your conclusions if the presence of chlorine in the Missouri River at Fort Bellefontaine was attributable to the Kaw, if the volume of the Missouri River would be very high?

A. You mean extremely high?

Q. Yes?

A. And the volume of the Kaw River would be very small?

Q. No, that isn't what I mean, doctor. I understand that the conditions that would make the Kaw River high would make the Missouri River at that point high, and the conditions that would make the Misouri River low, would make the Kaw River low, as they come practically from the same watersheds.

A. But then sometimes the Kaw River may be high because it comes from an entirely different direction and drains 300 miles and a great many tributaries besides.

Q. Assuming that it should appear that the volume of the Kaw River throughout the year was very small in comparison with the Missouri River throughout the year, would that fact change your conclusion that the chlorine in the Missouri was attributed to the Kaw and not to sewage pollution?

A. If such conditions as you describe just now would prevail at the time of considering that question, the immense dilution of the chlorines, first in the Kaw, and then again in the Missouri River, would practically wipe out the effect of the addition from the Kaw River as far as the effect upon the Missouri. 2633

MR. WOERNER: You mean by that it wouldn't be noticeable in the Missouri?

A. It wouldn't be noticeable if these conditions would prevail that Mr. Todd describes, at the time of the consideration of the question.

MR. TODD: Now, doctor, when you made the nitrate test —

A. Do you mean the nitrate or the nitrite?

Q. The nitrite test. Was the nitrite test made on the water directly or after filtration. Do you understand my question? Was it made upon the waters of the Missouri River before filtration or after filtration?

A. Well, the laboratory test included the clarification by Aluminum hydrate.

Q. Did you run it through a filter before making the nitrite test?

A. No sir; it was clarified by adding alum.

Q. That is, the water in the natural state from the Missouri was clarified by adding alum?

A. Yes sir, that is necessary because a clear solution of 2634 the sample must be obtained in order to make the Griess-Warrington nitrite test.

Q. After the addition of alum was the water filtered?

A. Yes, of course.

Q. And after the filtering the tests were made?

A. Yes sir.

Q. Doctor, you stated that you were never in Kansas City, Kansas, didn't you?

A. Yes sir.

Q. That's what I understood you to say?

A. Yes sir.

ADJOURNED until 2:00 P. M., same day, Thursday, April 2, 1903.

2635 Southern Hotel, St. Louis, Missouri. 2:00 P. M., Thursday, April 2nd, 1903. Continuation after recess. Present, the Commissioner and same counsel as before, representing the respective parties.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for further cross-examination by Mr. Todd and testified as follows:

Q. Before taking up that other topic, doctor, I want to ask you one or two questions. How long have you known that the waters of the Missouri were potable?

A. Since 1899.

Q. You have always been an advocate of using Missouri River for consumption in the city, have you not, since you have been city chemist?

A. Yes sir, but used under certain circumstances connected with the—

Q. You have agitated the use of Missouri River water have you not?

A. In preference to that of the Mississippi at the present intake.

Q. At the present intake?

2636 A. Yes sir.

Q. When did you first entertain those views in regard to the Missouri River water as being the best water to be used in the city of St. Louis?

A. In 1899.

Q. Previous to that time did you have any views on the subject?

A. No sir, not on the Missouri River as a preferable source for our water supply.

Q. When did you first become connected with the city as City Chemist,—what year?

A. In 1893.

Q. At the time that you became City Chemist, did you know of the contemplated building of the drainage canal of the Sanitary District?

A. Yes sir.

Q. When did you first learn of that contemplated improvement?

A. Well, that had been on visits to the city of Chicago previous to 1893.

Q. Did you read anything about the building of that canal in the newspapers of St. Louis, at the time that the bills were passed in the legislature of Illinois at Springfield?

A. Well, that is prior to 1890, isn't it?

2637 Q. Yes, 1889?

A. 1889—no sir, not at that time.

Q. And from 1889 on to 1893 or 1894, was anything said about the canal and its construction, in the papers of St. Louis, that you know of?

A. Yes sir, the matter was discussed in the year 1893 to some extent.

Q. It was a matter of general knowledge then in St. Louis that this improvement was being made in Chicago, was it?

A. Yes, it came up before the Board of Health in the form of discussion of a resolution introduced in the year 1893.

Q. And who introduced the resolution, doctor?

A. I believe the Health Commissioner of St. Louis at that time, Dr. George Homan.

Q. Have you a copy of that resolution?

A. I have it not on hand just now, but it is published in the annual report of the Health Department for that year. I could produce it.

Q. Could you state in the absence of the resolution,—which I would like to have you produce,—the contents in substance of what that resolution was?

A. Now, as far as I can recollect it—this is quite a long time ago, there were several resolutions. One resolution was that in view of the construction of the drainage canal
2638 at that time going on in Chicago—

Q. That was in 1893, was it?

A. Yes—a national board of experts should investigate that question as far as it would affect the water supply of St. Louis and questions in general pertaining to sewage pollution. The Board of Health recommended in the resolution either that Representative Barthold of St. Louis in Congress, should introduce a measure asking for such an investigation, or that such a measure had already been introduced by Mr. Barthold, and was supported by this resolution. The other resolution was calling upon the City Chemist to perform some analyses of samples of water,—he was to collect them from the mouth of the Illinois, down to the city of St. Louis at that time, from the Mississippi River and the Illinois River.

Q. Were these resolutions passed?

A. Yes, sir.

Q. And was that all the action that was taken at that time?

A. Well now, I don't recollect whether the recommendation of the Board of Health made to the Mayor of St. Louis, for an injunction suit in the Federal Courts against the construction of the drainage canal, whether that was the result of the analyses that I made of the water or whether it preceded this investigation. I cannot recollect at this time, because it is nearly ten years ago.

2639 MR. JEFFRIES: We object to the question and move that the above question and answer be stricken out because it is immaterial and not responsive to the issues involved in this case.

Q. MR. TODD: Can you secure for me the copies of those resolutions and the recommendations of the President of the Board of Health to the Mayor?

A. Yes sir.

Q. And will you do so and produce them here?

A. Yes sir. I can furnish you with a copy of the annual report in which the proceedings of the Board of Health are printed, and these resolutions are verbally copied.

Q. And do you know whether the recommendations in regard to an injunction, that was communicated to the Mayor of the City was ever presented to the city council here or not?

A. Well that I don't know, because it was presented to the Mayor of St. Louis and what became of it after that I could not tell you, I do not know.

Q. Did you make a cross-section of the waters of the Mississippi River above Grafton?

A. No sir.

Q. Did you make a cross-section of the waters of the Illinois River before the same entered into the Mississippi river at Grafton?

A. No sir, not at Grafton.

2640 Q. Did you make a cross-section of the Mississippi River below Grafton?

A. Yes sir.

Q. Where, doctor?

A. At Alton and at Hartford.

Q. How far is Alton below Grafton?

A. Alton below Grafton? I will have to look that up *exactly*. *I have it in the record here.* Alton is located sixteen miles below Grafton.

Q. How many samples were taken at Alton in that cross-section, doctor?

A. Five.

Q. Where were the samples taken?

A. That is, whenever a cross-section was taken,—five cross-sections, five points were selected in a line across the river.

Q. At the same time.

A. And the samples taken at that point, the number of days when these cross-sections were taken cover about a month,—every day.

Q. There were five samples taken crossing the river each day for about a month?

A. Yes sir.

Q. And where were the samples taken from?

A. There were collectors in a skiff who would row across 2641 the river in as straight a line as possible, and the samples were taken then in the customary way, from the river, direct from the skiff.

Q. I mean, how far apart, doctor, that is what I want to get at?

A. Well that I don't know exactly, but the distances were evenly divided in the five parts—into five parts in accordance with the samples.

Q. Then where were the next samples taken?

A. At Hartford in the Mississippi, one mile above the mouth of the Missouri.

Q. And how many samples were taken there, doctor?

A. Also five samples in the same manner and form.

Q. For what period of time?

A. For about a month.

Q. And were the samples that were taken at Alton taken during the same months and days that the samples that were taken at Hartford—

A. Practically; there were a few samples taken at one point I believe, which the record will show. I don't remember it just this moment.

Q. No, but did they cover the same period of time in both places, the same months?

A. Yes sir.

2642 Q. What month was it, doctor, that these examinations were made at Alton?

A. In the month of November.

Q. What year?

A. 1901.

Q. And the same in November, 1901 at Hartford?

A. Yes sir.

Q. Did you make any cross-sections in November, 1901, at any other place except Alton and Hartford?

A. Yes sir.

Q. Where, doctor?

A. At the chain of rocks, that is St. Louis Waterworks, in the Mississippi River.

Q. How many did you make there?

A. On five different days from November 25th to November 30th.

Q. How many samples did you take?

A. Twelve samples were taken across the river.

Q. November 25th to November 30th, twelve samples were taken across the River at the Chain of Rocks?

A. Yes sir.

Q. Were any more samples taken at that time in cross-sections except at Alton, Hartford and Chain of Rocks?

2643 A. Yes sir, there were some cross-sections taken from the Illinois River.

Q. Where were the cross-sections taken, from the Illinois River, doctor?

A. They were taken at points between Peoria and Pekin and at Pekin.

Q. How many samples were taken at Peoria—I mean in November?

A. I will have to look up the record sheet to tell you.

Q. How many samples were taken at Pekin in a cross-section?

A. I cannot recollect this moment; I have the sheet here, though.

Q. Were any samples taken at the mouth of the Illinois River?

A. For cross-section?

Q. Yes?

A. No sir.

Q. Were any samples taken at the mouth of the Missouri River in November for cross-sections?

A. Not from the mouth but at Fort Bellefontaine, two cross-sections were taken.

Q. Where was the first one taken?

A. At Fort Bellefontaine, on November 29th.

Q. How many samples were taken there?

A. Eight samples were taken across the river.

2644 Q. And where were the next samples taken—that was when?

A. On November 29th.

Q. And were any taken at any other place?

A. Then again on the following day, on November 30th, another cross-section was taken at Fort Bellefontaine.

Q. Any other place except Fort Bellefontaine that samples were taken in cross-sections?

A. In the Missouri River?

Q. Yes.

A. None.

Q. In deciding on the different waters of the different rivers that were found at the Chain of Rocks that investigation is confined to the period of November 25th to November 30th, is it not?

A. As far as the cross-sections are concerned.

Q. The cross-sections.

A. Yes sir.

Q. Now Alton is how far below Grafton?

A. Sixteen miles.

Q. And Hartford is how far below Alton?

A. 14 miles—no, excuse me—yes, fourteen miles, yes sir.

Q. And Hartford is how far from the Chain of Rocks?

A. Nine miles.

Q. If you made no cross-sections of the Illinois River—
2645 or how far is Pekin from Grafton?

A. I couldn't tell you exactly at this moment, I haven't got the figure.

Q. Approximately, doctor, if you can,—100 miles?

A. It must be more than that, the distance between Peoria and Grafton is 157 miles—between Peoria and Grafton.

Q. Well Pekin is about fifteen or twenty miles from—

A. Yes sir, I cannot recollect whether it is fifteen or twenty.

Q. Well, we will assume that it is 25, for the sake of what I want to illustrate.

MR. JOHNS: It is about fourteen miles by river.

MR. TODD: Fourteen miles by river. Then Pekin would be about 140 miles from Grafton?

A. Yes, according to that estimate.

Q. On November 5th these samples were taken at Pekin, were they? I mean between November 25th and 30th, were samples taken at Pekin.

A. You mean those cross-sections?

Q. Yes.

A. Well, I couldn't tell you at this moment; I would have to look up the sheets.

Q. I wish you would ascertain that if you have got the information.

2646 A. I have the sheets or the table here. I have here the analytical record sheet specifying on what days those cross-sections in the Illinois River were taken, and how many at each point on the respective days.

Q. Well, I want Pekin doctor; that will do me for my question. I want the date.

A. At Pekin Bridge?

Q. Yes?

A. There were taken on November 12th, 16th, 19th, 23rd and 26th, in 1901, two samples on each day from the Illinois River at Pekin Bridge.

Q. Two samples?

A. Yes. The cross-section taken was as follows: Two samples were taken from the river going down the stream right and left—

Q. That is all I want. Just two samples. Now in order to ascertain between the 25th and 30th of November, at the Chain of Rocks, the component constituents of the waters of the Mississippi as to whether the water there was Missouri, Mississippi or Illinois water, you would be confined to the data from the period between November 29th and 30th, would you not, as those are the only two days that the cross-sections were made in the Missouri River?

2647 A. Well if the conclusions to be derived from the analytical data would depend upon the cross-section—

Q. Well, doesn't the conclusion which you arrive at depend upon the cross-sections?

A. That depends upon conclusions in what respect, because I—

Q. As to the character of the waters at the Chain of Rocks in the Mississippi River?

A. Not altogether.

Q. Then what was the purpose of taking twelve samples of water across the Mississippi River at the Chain of Rocks, between the period of November 25th and November 30, daily?

A. I said that it was not dependent altogether upon those cross-sections, but the cross-sections of course gave me certain information that I wanted to obtain from the cross-sections in order to obtain facts that the cross-sections would reveal to me.

Q. Well, when the cross-sections failed to reveal the facts that you were looking for, would you go anywheres else for those facts?

A. Yes sir.

Q. Where would you go?

A. Well, I would take all the analytical data that I could
obtain, on that question and consider them from a general
2648 standpoint as every chemist would.

Q. What facts were you looking for, doctor, that were not revealed to you by the cross-sections?

A. You mean what facts I was looking for in taking the cross-sections?

Q. No. You stated that if the cross-sections did not reveal the facts that you were looking for, you went elsewhere to find the facts?

A. Yes sir.

Q. Now what facts were you looking for that the cross-sections did not reveal?

A. I was looking for a large number of facts in connection with nitrites and chlorides for which the cross-sections were taken.

Q. And what were you trying to prove by cross-sections—that these waters mixed and went into the Intake?

A. Yes sir.

Q. And if these cross-sections did not reveal that fact then you went elsewhere to find that fact to prove that they mixed and went into the Intake, did you?

A. Well, I said in connection with the general analytical result, I would take the result of the cross-sections and consider them.

Q. But you would not consider them by themselves, would you?

2649 A. Not in determining that question entirely. I would take into consideration the total solids, which total solids were not estimated in these cross-sections that I looked for.

Q. If this cross-section made at the chain of rocks, at Hartford, and Alton, at Bellefontaine and at Pekin, did not prove conclusively to your mind that the waters of the Illinois River entered the intake of the City of St. Louis, did you go anywheres else for any facts in order to establish that fact?

A. Well, in reviewing the analytical results from these cross-sections my views were strengthened as to the currents coming down the Mississippi River, at the intake.

Q. Then before you made these cross-sections—

A. No, at the chain of rocks, I want to say.

Q. Then before you made these cross-sections, you had views that the waters of the Illinois entered the Intake tower of the city of St. Louis, did you not?

A. Yes sir.

Q. And these cross-sections were made to confirm that view?

A. Yes sir, as far as nitrites and chlorines could confirm that view, because I only took cross-sections for that purpose.

Q. And if it failed to prove that fact conclusively, where else did you go for evidence to prove that fact?

2650 A. Well, these conclusions that I drew were to my mind sufficiently definite to dispense with a further investigation of that problem. I had settled in my mind the question that I wanted to have answered by the general analyses, and in a measure as far as it can be done, by the estimation of nitrites and chlorides, substantiated by these nitrites and chlorides.

Q. Did the cross-sections which you have stated were taken —did those cross-sections establish independently the fact that the Illinois river went into the Chicago Intake?

A. You mean the St. Louis intake, yes sir.

Q. Independent of anything else?

A. I beg your pardon. You mean St. Louis intake, because you asked for the Chicago intake.

Q. The St. Louis intake?

A. No sir, I had formed an opinion on that question prior to the taking of the cross-sections, but I wanted to see what the cross-sections would reveal in substantiating from the standpoint of the chlorides and nitrites, the opinion that I had formed on that question.

Q. So that when you started in upon this line of investigation you already had an opinion in regard to the waters of the Illinois mixing—going into the St. Louis intake?

A. Yes at that time, in November, 1901.

2651 Q. 1901?

A. I had an opinion.

Q. Now in the investigations that you made at those times to substantiate your previous opinion, did you consider any dates except the 29th and 30th of November, in connection with these cross-sections?

A. Well, in looking over the analytical results I considered these data as I had obtained them from the collection and analyses of those samples.

Q. Well now, in the Missouri River you only took two cross-sections on November 29th and 30th?

A. Yes sir.

Q. Wouldn't it be fair to limit your investigations in the cross-sections at the chain of rocks in ascertaining the St. Louis water, to November 29th and 30th?

A. No sir, that wasn't necessary, because I had practically formed an opinion as to that question prior to the taking of those cross-sections. The cross-section at—

Q. Then if you had that opinion already formed, what was the use of going to all this trouble in making cross-sections at these different points?

A. Simply if possible to corroborate and substantiate my opinions previously formed on the previous investigation.

2652 Q. Doctor, during the month of November, 1900, were any samples taken at Grafton, in the Illinois River?

A. Well, I will have to look up my data; I am not quite sure. We took samples regularly every day in 1900, from January 23rd, until October 11th, at Grafton, and subsequently some additional samples were taken, but I could not tell you at this moment whether they were taken daily or taken semi-weekly or tri-weekly, but there were some taken for the remainder of that year at Grafton.

Q. Well, were they taken in November?

A. Well I would have to look up my data. I have the sheets here. I can tell you in a minute.

Q. I wish you would?

A. After the termination of that investigation of daily collection of samples for that second period, from January 23, until October 11th, after the termination of that period of these daily collections at Grafton, samples were taken at Grafton on October 15th, October 16th, October 24th and October 30th. Now I haven't got any additional data on hand to tell whether any collections were made in November, 1900.

Q. What is your best judgment about it, doctor?

A. Well there are so many data here, of 8,000 analyses, that I cannot recollect at this moment, but it is my impression that no additional samples were taken in the year 1900 at 2653 Grafton, Illinois, after October 30th, but I am not positive about it. The next samples taken were in 1901.

Q. Were there any samples taken in the Mississippi River above Grafton during November, 1901?

A. Not if there were no samples taken from the Illinois River because the samples were usually taken from both points together, on like days.

Q. Have you got the data with you so that you could tell what the chemical analyses showed of the sample that was taken nearest the Illinois shore at Alton in the cross-section?

A. Yes sir.

Q. On November 29th?

A. Yes, November 29th.

Q. The sample nearest to the Illinois shore?

A. Yes, that is at Alton, for nitrites .010; for the chlorides it was 9. These figures represent parts per million.

Q. Yes.

A. And as regards nitrites, of course nitrogen in the form of nitrites.

Q. Now what was the sample next to the Illinois shore at Hartford on that same day, November 29th?

A. For nitrites .009; for chlorides 7.3.

Q. Were those two samples Illinois River water?

2654 A. I beg your pardon?

Q. Were those two samples that you have just spoken of as being nearest to the Illinois shore at Alton and nearest to the Illinois shore at Hartford, Illinois river water?

A. Well that I could not tell without consulting the data for Grafton, Illinois, and the samples.

Q. You didn't have any data for Grafton, Illinois, on that day, doctor, November 29th?

A. Yes, for 1900. You are now comparing the cross-sections taken in November, 1901.

Q. Yes, that is the time I mean—

A. And then you want me to look up the analytical data for November, 1901.

Q. On the 29th of November, 1901 at Grafton, you stated there were no samples taken?

A. No sir, 1900. You said 1900, and I—

Q. Well did you take any samples?

A. I was very careful to listen. That is why I said that the long investigation conducted from January 23rd, 1900 until October 11, 1900 was continued for a few samples at Grafton up to October.

Q. Well, let us go back and get that right. State whether any samples were taken at Grafton on the 29th of November, 1901.

A. Yes sir, that was the investigation of 1901.

2655 Q. I am right about the dates of the cross-sections at Alton, Hartford, Chain of Rocks and Fort Bellefontaine, —were taken in November, 1901?

A. Yes sir.

Q. And at Pekin?

A. Yes sir.

Q. Now at Grafton, in November, 1901—

A. Yes sir. You want the results for which date?

Q. No, I want the number of samples taken.

A. In 1901?

Q. At Grafton in the Illinois River?

A. They were taken from October 4th, 1901, daily until December 19th, 1901.

Q. Now will you look at November 29th and tell me whether those two samples that you have given me in regard to nitrogen and chlorines was Illinois River water?

A. The analytical results compared from the Illinois River at Grafton during that period, and the analytical results received from the analyses of the samples at Alton show a reduction of nitrites there at Alton.

Q. Give me the nitrites on November 29th, 1901, at Grafton.

A. They were .04.,

Q. Now the chlorines?

2656 A. The chlorines 19.5.

Q. Were any samples taken in the Mississippi River above Grafton on that day?

A. Yes sir.

Q. How many?

A. There were daily samples taken at the point in the Mississippi River above Grafton, from, I believe October 4th, 1901, until December 14th, 1901. To be sure, I will have to look up the sheet. (After referring to tables.) That is correct, from October 4th until December 14th, 1901.

Q. Now take the sample of water on November 29th, 1901, that was taken in the Mississippi River on that date, and the sample of water that was taken nearest to the Missouri shore at Alton and nearest to the Missouri shore at Hartford and tell me whether that was Mississippi River water or not, at those points?

A. On November 29th, the sample collected from the point in the Mississippi River several miles above the mouth of the Illinois, showed no nitrites and showed chlorines three parts per million. The sample collected in the cross-section at Alton on November 29th—

Q. Next to the Illinois shore?

A. No, next to the Missouri shore, you are asking.

Q. Missouri shore.

2657 A. Next to the Missouri shore showed no nitrites and showed chlorines four parts per million.

Q. What is your conclusion as to that sample of water at the point, where that sample was taken, as to whether it was Mississippi River water or not?

A. My conclusion would be that that—well now, whether that was Mississippi River water or not, I would have to compare additional data, for instance, compare the ammonias and compare total solids to get an absolutely correct estimate, and also the nitrates, but since only—

Q. Well, did you make a table of ammonias and total solids in order to ascertain that fact?

A. Well not for those points.

Q. Well I mean at that very point on that day?

A. No sir, I did not, but as far as the nitrites and the chlorines are concerned, it would show a remarkable resemblance between the water found in the Mississippi River above Grafton and the water found at the point opposite Alton in the Mississippi River close to the Missouri shore,—a remarkable resemblance.

Q. Now will you take that same day at the same relative position to the Missouri shore at Hartford?

A. Yes sir. At Hartford there were nitrites found, that is nitrogen in the form of nitrites .004, at the point closest to 2658 the Missouri shore, and chlorides six parts per million.

Q. And what does that show, doctor?

A. That shows a slight increase in nitrites at Hartford on the Missouri shore and a smaller amount of chlorides found on the Missouri shore—No, no—a reduction of chlorines—

Q. A reduction of chlorines?

A. Yes sir, from six parts per million to four parts per million.

Q. And what would you conclude as to whether that was Mississippi River water or not at Hartford?

A. The cross-section showed at this point, at Hartford, what it showed for Alton, that as you go across the river from the Missouri shore to the Illinois shore, an increase in nitrites and chlorines, as you go across the river in the cross-section.

Q. I am speaking of that sample taken at Hartford there next to the Missouri shore; doesn't that show again that that is Mississippi River water, if the analysis shows anything?

A. Well, as compared with the water running down the Illinois shore at those points where the nitrites are much higher and the chlorines higher, it would show that there is still a difference between those two currents there running along each shore, but it would show that while the sample taken from the point at Alton, as regards nitrites and chlorines is re- 2659 markably similar to the sample found in the Mississippi River above the mouth of the Illinois at Grafton; that there is a slight increase in nitrites and in chlorines in the samples taken from the Missouri shore at Hartford.

Q. Well what does it show as to the character of the water?

A. Well, it shows that while the samples taken at Hartford there from the Illinois shore show higher nitrites—

Q. No, I mean as to its being the water of the Mississippi River?

A. Well, there are still two currents there at Hartford, but that the Mississippi River water presumably running along the Missouri shore had been slightly polluted, that is, the increase in nitrites and chlorines although small, yet would signify or indicate some increase there in these impurities.

Q. Wouldn't that difference be found in two samples taken at the same place in the Mississippi River twenty minutes apart?

A. Well, how do you mean, twenty minutes apart?

Q. That is, you take a sample now in a certain place in the Mississippi above Grafton, and in twenty minutes you take another sample of water wouldn't that variation in the water at the same time and place be likely?

A. Well, I haven't any data to base a conclusion on that question.

2660 Q. Are the waters of the Mississippi River uniform at all times of the day?

A. What part of the Mississippi do you refer to?

Q. Above Grafton?

A. You mean whether it is uniform—

Q. As to nitrites and chlorines?

A. You mean that day?

Q. Yes?

A. Well, that I could not say because I didn't take two samples on one day from that point.

Q. Well, don't samples in all rivers that you have investigated, vary each day?

A. Well, from some points the sample shows a uniformity in some results, that is, in some ingredients, uniformity going on for days and weeks, sometimes, and then again it may not show the uniformity in other results for that time.

Q. Now, doctor, upon the day, the 29th of November, when you got down to the Missouri River, wouldn't the Missouri River itself press the waters of the Mississippi towards the Illinois shore by the time it got to the Chain of Rock?

A. Well, it will always push the water somewhat toward the Illinois shore, because of the manner in which it comes down the Missouri River and during the larger part of the year this volume being quite large, it would press the Mississippi
2661 River somewhat toward the Illinois shore; that is correct.

Q. And when it does that, the water that enters the Intake would be the Mississippi River water or the Missouri River water mixed with the Mississippi River water, would it not?

A. Well, it follows that if the pressure is very great and the volume of the Missouri River water—I mean if the volume of the Missouri River water is very large, and the volume of the Mississippi River not so large, that the pressure of the volume of water would be to push the Mississippi so close to the Illinois shore that on such days nothing but Missouri River water would enter the intake at the edge of the channel in the Mississippi—the intake of the water works.

Q. And at other times nothing but Mississippi River water would enter?

A. The condition might be the reverse, and then the intake being located fifteen hundred feet from the Missouri shore would receive at that time nothing but Mississippi River water as it comes down the river.

Q. Just above the intake, doctor, do you know whether it is true or not that there has been a sand-bar formed in the Mississippi River?

A. Yes sir.

2662 Q. And does the water that strikes that sand-bar go over toward the Missouri shore, or over toward the Illinois shore?

A. Now it can happen—I have been at that point frequently and investigated its condition—it can happen that the sandbar at a very low stage of the river is affected in that respect.

Q. In what respect, doctor?

A. That the water would sweep around that sand-bar, and I have seen considerable of an angle, and be pushed over toward the Missouri shore. I guess that is what you refer to?

Q. And keep the Missouri River towards the Missouri shore?

A. Yes, push it a little more toward the Missouri shore because this water at an angle, it would come around that sand-bar with considerable pressure and would press the Missouri closer toward the Missouri shore.

Q. At these times, would the water in the Intake be from the Missouri or the Mississippi?

A. At such times it would be from the Mississippi, because you are speaking now of the crowding of the Missouri River towards the Missouri shore by the Mississippi River current.

Q. Have you from your analyses been able to ascertain at what point below the discharge of the Illinois river into the Mississippi the waters of the Illinois and the Mississippi become commingled?

2663 A. Well, that depends upon what you define as commingling there.

Q. That is, thoroughly mixed with each other, so as to partake of the identity altogether of itself?

A. In the channel there is a considerable of a mixture, varying constantly almost from day to day.

Q. Does the Illinois river preserve its identity near the shore up to the time it reaches the chain of rocks?

A. The Missouri River?

Q. The Illinois, along the Illinois shore?

A. Well, the analytical results of samples taken at Hartford and Alton in the Mississippi River, as compared with the analytical results of samples taken at the Illinois shore opposite the intake, always show by comparison somewhat less impurities in the sample of the Illinois shore, at chain of rocks, than the samples at the Illinois shore, at Hartford and Alton. That would show some mixing effect of the Mississippi and Illinois Rivers at the point on the Illinois shore if the sample was taken opposite the intake.

Q. • Did the water next to the Illinois shore at the chain of rocks show less nitrites than the water at Hartford next to the Illinois shore? It does, doesn't it?

A. I cannot recollect from the analytical data whether
2664 they always do, but they practically do during the year.

Q. And the waters next to the Illinois shore at Hartford show less nitrites than at Alton, don't they?

A. Well, at Alton and Hartford those nitrites run pretty much alike; there is sometimes a slight reduction in nitrites,—very slight,—found in the samples taken at Hartford as compared with the samples taken at Alton.

Q. But there never is an increase in nitrites in the samples next to the Illinois shore over those at Alton, is there?

A. Well, sometimes there is a very slight increase shown, but as a rule they are pretty much alike.

Q. Have you made any calculations on the percentages of decrease in nitrites of the waters of the Illinois from Grafton down to Alton, in going that distance?

A. No, but there is invariably a decrease noticeable in the analytical results of the nitrites found at Alton as compared with the samples taken from the Illinois River at Grafton.

Q. And do you attribute that to the mixing of the Mississippi River or to the natural fermentative changes that take place in the water?

A. I think that it may be due to either cause. It is difficult to determine to which cause in all those instances, it would be due to; it may be due to either.

2665 Q. And the same thing of the Chain of Rocks?

A. You mean for the sample found at the Illinois shore?

Q. Yes, the Illinois shore?

A. Yes sir.

Q. If that is true, that it may be due to the fermentative changes the Illinois River would retain its identity along the Illinois shore down as far as the Chain of Rocks, wouldn't it?

A. Well, it cannot retain its indentity since the reduction in the nitrites and the reduction in other ingredients found in that water is noticeable.

Q. I mean its identity subject to the natural loss of purification in going that distance?

A. Well, it cannot have the same identity because it differs somewhat in its analytical character, the water from the Illinois shore at the Chain of Rocks as compared with the water of the Illinois River at Grafton.

Q. Have you made an analysis of the waters of the Illinois River for a distance of 39 miles immediately above its mouth to Grafton?

A. Do you mean at a point 39 miles above Grafton in the Illinois River?

Q. Yes?

A. No sir.

2666 Q. You don't know how much the varying changes would be for the samples taken 39 miles above Grafton on the Illinois River, to Grafton, do you?

A. No sir.

Q. Do you know whether it would be any greater, any greater change than is evidenced by your analyses from Grafton to the Chain of Rocks, along the Illinois shore?

A. I don't think the change would be so great in the Illinois River from the point 39 miles, as you state.

Q. That is the distance I think from Grafton to the Chain of Rocks?

A. As the change would be from Grafton to the chain ot rocks.

Q. On what do you base that, doctor? Have you made any experiments of it?

A. Because of the fact that the Mississippi River connects with the Illinois River at Grafton, and that the Missouri River connects with the Mississippi River at the mouth of the Missouri.

Q. Is that the only reason you have for believing to the contrary?

A. Well, that would change the conditions materially and bring about a different situation than exists in the Illinois river between the point 39 miles above Grafton and Grafton.

2667 Q. Do you know what percentage of Mississippi water and the Illinois River water is in the channel of the Mississippi River at Alton?

A. No sir.

Q. Have you any way of ascertaining that fact?

A. I think that the same principle applied—

Q. I ask you if you have any way of ascertaining it?

A. Yes, there is a way, there would be a way.

Q. Why didn't you ascertain that fact, doctor, in your investigation, if it was possible, so as to give the percentage of water from the Illinois, and water from the Mississippi, that is found in the channel of the Mississippi River at Alton?

A. Because the analytical data revealed to me certain chemical conditions found in the samples taken from the channel of the Mississippi between the mouth of the Illinois and the mouth of the Missouri, that I feel justified in drawing conclusions as to the mixture from a general review of the analytical data of the samples taken from the Mississippi River above the mouth of the Illinois at Grafton, and from the Illinois river above the mouth of the Illinois, and from Alton. By comparing the general analytical data I formed the opinion that there is some mixture taking place in the channel.

Q. But the amount of that mixture you did not ascertain?

2668 A. No, I thought approximations would suffice for the purposes of my investigation.

Q. And the same condition obtained at Hartford, did it. You made no investigation to ascertain the amount of Mississippi water and Illinois River water that constituted the channel of, the Misissippi at Hartford, did you?

A. You mean the Illinois and Mississippi compared?

Q. The Illinois and Mississippi at Hartford?

A. No sir.

Q. And when you got down to the Chain of Rocks, were you able to say how much Missouri River water, how much Mississippi River water and how much Illinois River water was in the channel of the Mississippi at the Chain of Rocks?

A. Well, I could by approximations form a conclusion as to the relative mixtures there prevailing at the chain of rocks.

Q. But as a matter of analyses were you able to do it?

A. Well, by studying the analytical data.

Q. Well, did you do it, doctor, is what I want to get at?

A. Yes sir.

Q. Now tell me how many parts in the channel of the Mississippi River at the Chain of Rocks was Missouri River 2669 water; how many parts Illinois River water, and how many parts Mississippi river water, if you did it?

A. That would depend entirely upon the study of the analytical data of certain days, and the analytical data reaching as far up as the mouth of the Illinois river.

Q. We will assume that you made that study. Now give me your conclusions?

A. Well, I can give only a general conclusion because these percentages, I won't call it percentages,—these approximations would vary from day to day.

Q. Wouldn't it be guess-work to try to do it?

A. No, it is based upon a study of the analytical data.

Q. Could you take a gallon of that water in the channel of the Mississippi River at the Chain of Rocks and tell how much of that water was Missouri River water, how much Illinois River water and how much Mississippi River water?

A. No sir, not that way.

Q. Could you anyway?

A. I could by a careful study of the analytical data obtained from the analyses of samples taken in the Illinois river a few miles above Grafton, above its mouth, samples analyzed as collected from points in the Mississippi River at Alton and Grafton, from the analytical data obtained from samples, also samples in the Missouri River.

2670 Q. Doctor, have you done that?

A. Yes sir.

Q. Well, will you tell me what are the parts of those three rivers making up the channel of the Mississippi River at the Chain of Rocks?

A. It is impossible to make these approximations without carefully studying for every case.

Q. You haven't done it then?

A. I carefully studied these analytical data. I have done so yes sir.

Q. Can you give me the result of your investigation?

A. No sir, I haven't those data at hand. I have done it though, taking the analytical figures.

Q. Have you testified to it in this examination?

A. No sir, I have not.

Q. Are you able to tell me the exact proportions of this water in the channel of the Mississippi River at the Chain of Rocks?

A. This would also include, as I stated, a separate estimation of the character of the Illinois River, as you say.

Q. At Hartford do the waters of the Mississippi contain as much mixture of the Illinois River water on the Missouri side as on the Illinois side?

A. Evidently not from the analytical data.

2671 Q. What proportion of the waters at Hartford near the Missouri shore, is Mississippi river water, and what proportion is Illinois River water?

A. You mean at Hartford?

Q. At Hartford, yes sir?

A. Well, that would depend upon a careful study of the analytical data of the two rivers before they meet.

Q. Do you know now, doctor?

A. Well, I cannot give you any exact figure without taking the special analytical data and going over them carefully and then making calculations.

Q. That is taking the analytical data and drawing conclusions from them, that satisfy your own mind as to the quantity?

A. As to the approximate quantities.

Q. Approximate quantities?

A. They are all approximations.

Q. All this is an approximation, isn't it?

A. As applied to what?

Q. To the different waters in the channel of the Mississippi River at the Chain of Rocks?

A. Yes sir.

Q. How much of the year do the waters of the Missis-
2672 sippi river and the waters of the Missouri River enter the intake at the Chain of Rocks?

A. The variations are so great there from day to day, that a general deduction as to how many days during the year or for how long a period the mixture of the Missouri and the Mississippi enters the intake, is difficult, unless we apply chemical results as found in the analyses of waters collected from the Mississippi River at Hartford; from the Missouri River at Bellefontaine and from the Mississippi River as it enters the Intake.

Q. Are you able to give it to me now; have you compiled that data?

A. Yes, I have for a period covering every day from January 23rd, until October 12th, I believe, 1900.

Q. Has that been testified to?

A. Yes sir.

Q. And did that contain the Mississippi river and Missouri River water all the time?

A. Well, those data, the table was presented; they demonstrated that there were days when, as based upon the estimation of the residue upon evaporation, called also total solids, as found in the samples of water taken from the Mississippi at Hartford, from the Missouri at Bellefontaine, and from the Mississippi as it goes into the intake; these estima-
2673 tions showed that as based upon the residue upon evap-

oration, approximately on some days, evidently only Mississippi River water went into the Intake, and at other days only Missouri River water went into the intake; then for the major part of the year there was a mixture of the two rivers going into the Intake, with varying percentages. At one time in that mixture the Missouri River would prevail and at other times the Mississippi River would prevail.

Q. Doctor, going up to Chicago, will you state what are the important chemical constituents of the Chicago sewage as discharged at Bridgeport into the canal?

A. The important chemical constituents of the sewage as is discharged from Bridgeport into the canal?

Q. That is at Robey Street, where the canal enters the Chicago river?

A. The principal constituents of the sewage going into the canal there would be classified as carbonaceous organic matter, and nitrogenous organic matter. There will be phosphate salts, there will be sulphate salts, and there would be tissues of various kinds of animal origin; there would be a number of organic compounds that are usually found in sewage, in the fecal matter. There would be refuse from manufacturing establishments which drain into the south fork of the south branch of the
267b Chicago River; there would be refuse from the gas factories located at that point, in addition to multifold other constituents of sewage of a minor importance as represented in the quantity of the sewage.

Q. Which, if any of these substances that you have described are in themselves, harmful?

A. Do you mean harmful to health?

Q. Yes, to health?

A. If that sewage as it is constituted when it enters the Illinois and Michigan Canal—well that would depend very much upon the quantities of various of these ingredients found, or present in that sewage.

Q. To what ingredients do you refer?

A. Well those that I have principally mentioned.

Q. Then the presence of all of those ingredients in what quantities would be harmful to health?

A. Well, it would be rather difficult to estimate the harmfulness of that sewage. It wouldn't be confined to those ingredients that I have mentioned. There might be in the sewage pathogenic bacteria, which in themselves would be harmful to health.

Q. Can you name any of the substances in the sewage that is discharged into the drainage canal at Robey street which are in themselves harmful to health, whether in large or small quantities?

2675 A. Well, the analyses of the samples taken from the drainage canal at Robey street, show certain chemical conditions—the chemical analysis I am referring to now, showed certain chemical conditions of that sewage, which if confined to the chemical conclusions would not justify me in saying if anybody would drink that water in the drainage canal at Robey street after that sewage would have entered it, that it would be injurious to his health as far as the chemical constituents are concerned, but that leaves out of the question all the bacteriological character of that sewage.

Q. Will you give me the names of any of the substances that are found in that sewage that are harmful to health as it enters the canal at Robey street in Chicago?

A. As far as the chemical character—that is, setting aside the bacteriological character—is concerned, the analytical results would not show the presence in the water from the drainage canal, would not show the presence of chemicals as revealed by the analyses of samples that were taken during this investigation, would not reveal that anybody who would drink that sewage laden water would be injured by chemical substances. It left out of the question of course, the bacteriological consideration.

Q. I want you to testify now, doctor, as a chemist?

2676 A. Yes, I say chemically.

Q. After a while I will examine you as a bacteriologist.

A. Yes, sir. There is a question of the potability of that water. It may not show any chemical ingredient that would injure anybody that drinks that water. You can drink sewage, what you call pure sewage, although impure, and there may be no pathogenic bacteria in that sewage and it may not do you any harm.

Q. Well, is there anything, any substances in the sewage discharged into the drainage canal at Robey street that are dangerous to health as ascertained by you as a chemist?

A. The chemical analyses alone, not considering the bacteriological analyses?

Q. I have asked you to leave out the bacteriology.

A. The chemical analyses alone would not reveal that.

Q. Do your chemical analyses reveal anything in the discharge of the Chicago sewage into the drainage canal as being harmful to health?

A. It did not reveal anything directly, but general conclusions as to the potability of that water would result in a different opinion.

Q. Do your chemical analyses of the waters, of the sewage that was discharged into the drainage canal at Robey street in the city of Chicago, reveal to you any substances that were dangerous to public health? 2677

A. No, sir; not as such, chemically.

Q. What are the real dangerous elements in sewage to public health?

A. Well, there may be refuse. Chemically there may be refuses from manufacturing establishments that in their chemical character would constitute a direct danger to health, and there may be a bacteriological character of the sewage that may be such as to render it dangerous to health.

Q. What are the refuses from manufacturing businesses that are dangerous to health, that you mentioned in the first part of your previous answer?

A. That would depend very much upon the quantity of water with which these refuses would be mixed. There might be chemical factories, manufacturing various kinds of chemicals that in themselves would be poisonous unless greatly diluted. That is refuses there that would be cast into the river, might be refuses from gas factories, and may be so much of it would be discharged into such a little quantity of water that it would be insufficiently diluted and that would apply to a great many manufacturing establishments. It might apply to tanneries, too, and such things.

Q. In your investigations of the waters of the Illinois from

Lockport to the St. Louis intake, did you discover any of 2678 these elements such as you have last described, in the waters entering the St. Louis Intake, from the Mississippi River?

A. No, sir; I did not.

Q. What did you say were the other dangerous elements in sewage outside of the chemical products of manufactories?

A. It would be the pathogenic bacteria.

Q. Did you discover as a bacteriologist, any pathogenic bacteria in the sewage of the drainage canal at Robey street?

A. Not from my own investigation; that is from my own analytical investigations. Those I didn't make.

Q. Have you examined the tables that have been prepared on bacteria, and introduced here in evidence?

A. Yes, sir.

Q. Did you draw any conclusions from those tables?

A. Yes, sir.

Q. From those tables, do you know whether or not they disclosed any pathogenic bacteria as being present in the sewage at Robey street in the drainage canal?

A. Yes, sir.

Q. Was there any pathogenic bacteria in that sewage?

A. Yes, sir.

Q. What were they?

A. There was the coli communis found.

2679 Q. Was the coli communis a pathogenic bacteria?

A. The coli communis being an important factor in some diseases—

Q. My question, doctor, is, is it a pathogenic bacteria?

A. I consider it in a measure a pathogenic bacteria.

Q. In what measure?

A. In so far that it may be harmful in water to some people; to some individuals, and it may be harmless in water taken by other people.

Q. Does the coli communis become harmful when taken internally?

A. Some intestinal diseases are ascribed to the presence of coli communis.

Q. Are not the bacteria of coli communis found in the intestinal tract of almost every man?

A. There is abundant evidence that they are found in the intestinal tracts of many individuals.

Q. Is it not true as being universally found in the intestinal tract of man, whether healthy or unhealthy?

A. Well, in a great many.

Q. Then, how does it become pathogenic from being taken into the system?

A. That depends upon the individuality. What I would call the physical or physiological individuality of the person drinking such water. 2680

Q. Is it not a fact, doctor, and recognized by bacteriologists everywhere that the bacilli coli communis is non-pathogenic?

A. There are some authorities that will call it non-pathogenic, because in many individuals it is harmless, and then again there are others that call the coli communis pathogenic because it is harmful to others.

Q. Is it not a fact, doctor, that the only way that coli communis becomes harmful is when it is inoculated into the blood or into a cut, and not harmful when it is taken into the alimentary canal?

A. Well, some authorities assume that standpoint.

Q. What are the characteristics of the coli communis bacilli?

A. In what respect do you mean, in what characteristics?

Q. How is it distinguished from other bacteria?

A. Well, by methods of bacteriological examination.

Q. What are those methods?

A. I am not familiar with those methods because I am not an expert bacteriologist.

Q. You do not call yourself then an expert bacteriologist to-day, do you?

2681 A. No, sir; I never did.

Q. Then I have been mistaken, doctor. What kind of sewage, doctor, undergoes final oxidation the more rapidly, excreta products or undigested matter?

MR. JEFFRIES: Do I understand you have got three propositions there?

MR. TODD: No, the excreta products and the undigested matter.

A. That is very difficult to ascertain, if possible at all.

Q. Do you know anything about the relative time it requires for the final oxidation of these two classes, excreta products and undigested matter?

A. No, sir; because the relative presence in sewage of these various ingredients of the sewage, and taken together with the multifold kinds of sewage existing, and constantly varying make it impossible to determine that question.

Q. Do you know what proportion of the sewage of Chicago is composed of undigested products, and what proportion is composed of excreta products?

A. No, sir; it is impossible to ascertain.

Q. Take an example such as meat before digested, and meat after digested, which would take longer to oxidize?

A. Where?

Q. In the sewage?

2682 A. Which would take longer to oxidize?

Q. Yes?

A. I couldn't tell you, because that is difficult to determine.

Q. The meat before digestion or the product of meats after digestion, which is known as feces, and the urine?

A. Well, the feces would be in a state of initial fermentation which the raw meat would not be. The raw meat would very likely take longer, but I haven't made any investigations on that question and therefore cannot answer it from a scientific point of view.

Q. In the Chicago sewage, did you discover any sewage except feces and urine?

A. Well, now, in the Chicago sewage —

Q. At Robey street?

A. Then you mean practically in the water?

Q. In the water of the drainage canal; I will take the drainage canal as a starting point?

A. I only looked for certain chemical ingredients, indicating sewage pollution, as is customary in analyzing those waters taken from the drainage canal at Robey street.

Q. Were you able to ascertain from the sewage in the drainage canal, the presence of slaughterhouse sewage?

A. The chemical data obtained from the analyses would 2683 not enable a determination as to whether or not that sewage was of fecal matter or of refuse from slaughterhouses or how much of each there was represented in that sewage.

Q. What sewage would oxidize more rapidly, that from slaughterhouses or the fecal and urine discharge of man?

A. I couldn't tell you, because I have made no special researches in that line.

Q. What amount of sewage did you calculate was discharged into the drainage canal from Chicago?

A. I have stated that at times, the population of 800,000 people would drain sewage directly into the south branch of the Chicago River and the drainage canal being fed by the waters from the Chicago River, or rather from the water passing through the south branch of the Chicago River from the lake, I stated that at times the population of 800,000 Chicago people would drain sewage directly into the south branch of the Chicago River and thus directly into the drainage canal at times.

Q. How do you calculate the quantity of sewage of Chicago, doctor?

A. I compare the quantity of sewage as it is customary with engineers, with the water supply of the city.

Q. Then if a city consumes 100,000 gallons of water a day, would you figure the sewage at 100,000 gallons of sewage a day?

2684 A. Well—

Q. I simply use that to ascertain whether that is the principle?

A. Yes, that is the figure used for computation customarily.

Q. Doctor, is there any sewage, any elements of danger to public health, aside from the fecal discharge of man, or the urine of man, in sewage?

A. Yes, I said that there might be—

Q. Aside from the chemical productions of factories?

A. Well, it depends, if that sewage is free from chemical poisons that may have been introduced into it with the water from other sources than from chemical manufacturing—

Q. That's what I mean, eliminating the chemical manufacturing.

A. That would only be by willful pollution of an individual source, the introduction of chemical poisons.

Q. Aside from the contamination of the stream by artificial means, such as putting poison into it or something of that kind, the chief danger lies from the excreta of man, doesn't it?

A. The excreta of man and the discharges from manufacturing establishments as I specified.

Q. Aside from the discharges of manufactories?

A. There is no additional source of danger to be looked for.

2685 Q. Do you know what the average urine and fecal discharge of man is?

A. Well, that varies considerably according to the man.

Q. As an average, I mean. Dr. Ravold, I believe, testified on that point, that there was 43 ounces of fecal and urine discharged from the average person a day.

A. Well, I would accept that figure, too.

Q. That is approximately, is it?

A. Yes, sir.

Q. Now, in the sewage of a city what proportion of fecal and urine do you calculate in connection with water examination?

A. Well, that I couldn't tell you at this moment. I have studied that question and have some data, but I haven't got them at hand, and I would have to refresh my memory from those to be able to answer that question.

Q. Well, that is a proper subject of investigation, isn't it?

A. Yes, sir; it is.

Q. If there are 100,000 gallons of water consumed by a city a day of 5,000 people, the proportion of urine and feces discharged by those people, into 100,000 gallons of water is a proper subject of inquiry isn't it?

A. Yes, sir.

Q. And that enters into the question of dilution?

2686 A. Yes, it is an important matter whether the solid fecal matter or the liquid impurities represented by the urine, whether one or the other prevails and what the relative proportions are. It comes into consideration as to the average time required for proper oxidation of this sewage.

Q. And if the people in a city consume 60 or 70 gallons of water a day per capita, it is not exactly fair to say that for every man there is sixty gallons of sewage, without any mixing of it, is it?

A. Well, a town that would only consume so much water would have entirely different conditions of sewage disposal. The relative computation usually applied by engineers in estimating relative proportions of sewage in water supply, the relative computation would not be applicable.

Q. Do you recall the Commision of Hydraulic Engineers appointed by the City of St. Louis in 1902?

A. Yes, sir.

Q. On page 12 of the report on the water supply of the City of St. Louis, appears the following: "From investigations made upon the water systems of cities where the quantity of water used is measured, it appears that in large cities the average volumes needed for domestic, public and manufacturing purposes are respectively about 30 gallons, 5 gallons and 25 galons per day, for each inhabitant, and that any supply in excess of 60 gallons a day per capita goes to under-
2687 ground leakage or to unnecessary waste." Do you approve of that statement as to the quantity of water?

A. Well, that I couldn't do unless I had compared it with various statements of responsible engineers that have expressed an opinion on that subject.

Q. I mean from your own ideas and experience as a city chemist, do you regard sixty gallons of water as too large a consumption of water for the average man, woman and child, for a large city?

A. I cannot answer that question unless I have studied some data that I have to compare with those data in order to form a conclusion as to the accuracy of those data.

Q. What would be your idea of the amount of water that each party used in a large city, per capita?

MR. JEFFRIES: I object to the question for the reason that the witness has not qualified himself as an engineer expert on water supply. That is, as to the quantity of water to be supplied to each individual from the water system.

Q. MR. TODD: Can you answer the question, doctor?

A. As to the quantity of water which should be provided per individual, the larger the quantity of water of course the better for the sanitary conditions of the city. That is the way I would answer that question.

2688 Q. What is the extent of organic pollution from the Peoria distilleries and glucose works, doctor?

MR. JEFFRIES: If you know.

MR. TODD: Do you know?

A. I haven't made an accurate scientific estimate of that so I couldn't answer that question.

Q. Don't you deem that important to be ascertained, in order to arrive at a correct conclusion as to the contamination of the Illinois River below Peoria?

A. As far as the analytical results of the examination of samples of water taken from points in Illinois above Peoria, near Peoria and below Peoria are concerned, that question indirectly came into consideration.

Q. To what extent did you take them into consideration, doctor?

A. That the character of the pollution of the Illinois River from the distilleries and glucose factories at Peoria and Pekin required attention because the personal local investigation that I made at those points and the analytical results showed some connection with the analytical results of the refuse discharged into the Illinois River from the distilleries and glucose factories.

Q. Have you any idea as to the amount of that sewage
2689 as to volume and weight?

A. No, sir; not as to volume and weight.

Q. What amount in tons does it pollute the Illinois River at Peoria?

A. There is some pollution of the Illinois River at Peoria and Pekin from those discharges.

Q. In your investigation, doctor, of the sewage conditions at Peoria, did you make any?

A. I gave this pollution which is mentioned, some consideration, yes, sir.

Q. Did you ascertain it to be the fact that there is no city in the United States that flows as much sewage as the city of Peoria according to the population?

A. Now, Mr. Todd, do you mean that there is no city in the United States that produces more sewage in proportion to its population than Peoria?

Q. Yes, sir?

A. I haven't found that to be the case in my investigation of the sewage of the cities.

Q. Do you know anything about it, doctor?

A. I have given the matter of the sewage production and sewage disposal considerable study.

Q. Do you know about the Peoria sewage and the extent of it?

A. Yes, sir.

2690 Q. Do you know how many cattle are fed there every day?

A. Well, I have collected those data, but I haven't got them at hand and I would have to refresh my memory to give you an exact figure.

Q. Do you know how much of the products of the distillery and the glucose company is thrown into the Illinois River every day in tons?

A. I have some estimates and figures on that question, but I haven't got it at hand now, and I cannot recollect them.

Q. What is the composition of this polluting material in the sewage of Peoria?

A. Well, it is the same composition that other sewages show.

Q. Well, take the distilleries; what are the compositions of the sewage from the distilleries of Peoria?

A. Well, that is a certain swill of organic matter that is cast off as refuse.

Q. What is its nature, doctor?

A. Well, it is what we call a grain swill.

Q. What is the chemical composition of it?

A. Well, that I couldn't tell you off hand. I have studied that problem and have collected data on the subject, but I haven't got it at hand just now. It is organic compounds.

Q. What is the effect of this material in oxidation?

A. This material will in the course of time undergo certain changes, chemical changes, and will disappear in the 2691 run of the river into which it is discharged.

Q. Will it oxidize more slowly or more rapidly than household sewage?

A. Well, that I couldn't tell. I haven't made any investigation of that point, that question.

Q. Is its destruction rapid or non-rapid?

A. Well, that is the disappearance of this refuse from the distilleries has been established to my mind in certain cases, where analyses were made at points where that swill is introduced into the river and at points below after the swill had run a certain distance. I now distinguish the swill from the distilleries from other sewage such as household and fecal matter.

Q. Does it oxidize more rapidly than fecal matter and household sewage?

A. That I could not tell; but I have noticed in analyses that the disappearance of that swill was noticeable in running rivers.

Q. Where, for instance, doctor? Give me an example of where that swill disappears and the sewage from the distillery disappears in running rivers?

A. At Peoria, and at Pekin.

2692 Q. Do you know of any other place in the United States except on the Illinois River where that condition prevails?

A. Now, I have made no analyses of any waters where the proportion of so much of that swill in proportion to the population was discharged into the river, so I couldn't draw any comparisons in that respect. It is only my experience in drawing conclusions from the analytical data obtained from the examination of samples of water in the Illinois River.

Q. If it disappears rapidly, does it disappear more rapidly than household sewage?

A. That I couldn't tell.

Q. How do you distinguish it from the household sewage, doctor, in these tests?

A. Well, the analytical results would show in these tests after a river into which the swill had been discharged had run certain distances, that the effect of the introduction of that swill disappeared, and the physical character of the water, that is, by appearance, would demonstrate that, because this swill is very much noticeable in the water by the eye, at those places where it is discharged directly in such quantities as happens at Peoria and Pekin.

Q. Do you assert that as a fact that this sewage from the distilleries is detectible by the eye?

2693 A. At places where the discharge is in such large quantities as in the Illinois River at Peoria and Pekin, my own eyes have shown me this swill and refuse from the distilleries.

Q. How far from the place of discharge did you see this, doctor?

A. Well, I have seen it a number of miles down the Illinois River on trips of personal inspection that I made.

WILLIAM C. TEICHMANN.

Adjourned until 10:00 a. m., Friday, April 3, 1903.

2694 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Friday, April 3rd, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN resumed the stand for further cross-examination by Mr. Todd and testified as follows:

Q. Doctor, Teichmann, I hold in my hand the 17th Annual Report of the Health Commissioners of St. Louis. Will you state whether this is an authorized published copy of the proceedings of the Health Commissioner of the City of St. Louis?

A. It is the annual report of the Health Commissioner of St. Louis for the fiscal year 1893-1894, beginning with April 1st, 1893, and ending April 1st, 1894.

Q. I would like to have you identify certain parts of this report. On page 11 of this report there are two topics discussed: "Public Water Supplies," and "Illinois River Pollutions."

A. Yes, in the introductory report of the Health Commissioner.

2695 Q. That is correctly reported in this book, is it not?

A. Yes, sir; official publication.

MR. TODD: I offer page 11 of this report for identification.

MR. JEFFRIES: You don't offer it as evidence yet?

MR. TODD: No, I offer it for identification.

MR. JEFFRIES: I want to object to it when you introduce it.

MR. TODD: No, I simply offer it for identification.

THE COMMISSIONER: Let me suggest you had better give me a copy.

MR. WOERNER: You won't have to identify it; we will admit the identity of the book.

MR. TODD: That is all right then.

MR. JEFFRIES: Of course we won't admit its relevancy or its competency.

MR. TODD: I would suggest that all this that has gone before be stricken out, and just let me ask the question. I would like to have you identify the 17th annual report of the Health Commissioner of St. Louis.

MR. JEFFRIES: If it will serve your purpose we will admit that that is what it is.

MR. TODD: Counsel admits that this is the 17th annual report of the Health Commissioner of the City of St. Louis.

MR. JEFFRIES: We will make that admission for you
2696 at any time you want, Mr. Todd, as far as the admission is concerned.

Q. MR. TODD: Doctor, in 1893, did you make any analyses of the waters of the Illinois River?

A. Yes, sir.

Q. By what authority did you make these analyses?

A. By order of the St. Louis Board of Health.

Q. To what extent did you make analyses of the Illinois River?

A. I started with the collection of three samples on October 11th, 1893, from the Illinois River.

Q. At what points, doctor?

A. I believe it is three, five and seven miles above the mouth of the Illinois.

Q. How often were these samples taken?

A. Just on that one occasion we only had those three samples at these three points.

Q. On the Illinois River?

A. Yes, on the Illinois River.

Q. Three, five and seven miles above the mouth of the Illinois River?

A. Yes, sir; it is my impression. I will look up the analytical sheet here to be certain. (After referring to sheet): Excuse me, it was one, three and five miles above Grafton in the Illinois River.

2697 And when were those analyses made, doctor?

A. The samples were collected on October 11th, and on my arrival at St. Louis on October 12th, the samples were analyzed.

Q. Did you take any other samples of water in the Illinois River after that?

A. Not until September, 1899.

Q. In September, 1899, how many samples did you take of the waters of the Illinois River?

A. Well, I would have to look up the record. That was part of the investigation conducted prior to the opening of the Drainage Canal, and there were nineteen samples collected from the Illinois River during the months of September, October, November, December and part of January from the Illinois River.

Q. At what points, doctor?

A. That was points three and five miles above the mouth of the Illinois. That has been testified to in my report.

Q. I understand that. Now, in the examinations that you made of the water samples taken in 1893, what was the condition of the waters of the Illinois River?

A. The condition of the water of the Illinois River as demonstrated by the analytical results showed the presence of
organic matter as evidenced by free and albuminoid am-
2698 monia; the presence of nitrites to some extent and the
presence of high chlorines, proved contamination of the
Illinois River at the mouth.

Q. By sewage pollution?

A. Well, since only one set of samples were taken on that day, and I thought that a longer series of collections should be made, I did not pass any definite conclusions at that time on the character of that pollution, whether it was of sewage or vegetable origin at that time, and in my report to the Board of Health I stated that a more extensive investigation would be necessary.

Q. In 1899, when you made your examinations what conclusion did you arrive at as to whether the waters of the Illinois were sewage polluted or not at Grafton?

A. Well, I did draw the conclusion from the large number of samples collected and analyzed from the mouth of the Illinois at that time, that there was considerable pollution of the water.

Q. From what source—sewage?

A. Now, you refer to 1899?

Q. 1899; yes?

A. 1899. I stated at that time that the pollution found in 1899 was of a character indicating sewage pollution of the Illinois River.

2699 Q. Can you refer me to the part of the report which you made at that time in regard to the sewage pollutions of the Illinois River?

A. Yes, there were no samples collected after this investigation of 1899 prior to the opening of the canal at any point in the Illinois River above the mouth.

Q. That is what I mean, doctor, just at the mouth prior to the opening of the canal?

A. Yes, I have those conclusions here. One of the conclusions was the Illinois River at its mouth was badly polluted during the entire period of investigation, from September, 1899, until the middle of January, 1900.

Q. Before the opening of the canal?

A. Yes, sir.

Q. That refers—

A. Or rather, there were a few samples collected there after the opening of the drainage canal but at that time it was impossible for the drainage canal to have reached the mouth, so that is why I am justified in stating that those samples all refer to the time before any pollution from the drainage canal could have reached the mouth.

Q. Have arrived, yes. And in that investigation, did it demonstrate conclusively the character of the pollution,
2700 as to whether it was sewage or vegetable?

A. Well, my opinion was that it was sewage pollution.

Q. Sewage pollution?

A. Yes, sir.

Q. Now, from that investigation are you able to go back and review the data of 1899 and state whether the analyses at that time showed sewage or vegetable pollution?

A. Well, owing to the fact that in 1893 I had no data at hand to form an opinion of the character of the Illinois River water above the mouth, I refrained from stating at that time, in 1893, what the pollution found at the mouth of the Illinois River might be ascribed to, but in 1899, while I had no analytical data based upon original analyses of my own of the water of the Illinois further above the mouth than three miles and five miles, I consulted analytical data published by Professor Long of the State Board of Health of Illinois, and Professor Palmer, who performed a series of chemical investigations also of the Illinois River, and based upon the analytical data of Professor Long and Professor Palmer, I formed some opinion as to the nature of the pollution found at the mouth of the Illinois.

Q. In 1893?

A. In 1899. I mean that was in 1899.

Q. I am going back to 1893, doctor.

2701 A. In 1893 I refrained from drawing any conclusion as to the pollution found at the source, or the mouth, of the Illinois, because I had no data.

Q. But the character of the pollution is what I am asking you, not the source.

A. Well, I thought that it was just one sporadic analytical survey there, that would not justify a definite conclusion, and in my report I asked for an additional investigation—for means to carry on an investigation on a very large and exhaustive scale to determine that very question, where that pollution came from.

Q. In the examinations that you made in 1893, what did you find the albuminoid ammonia, high or low?

A. I found high albuminoid ammonia.

Q. In suspension or solution?

A. Well, I did not determine at that time the albuminoid ammonia in suspension or solution.

Q. How was the free ammonia, doctor, in that examination?

A. Free ammonia was comparatively low.

Q. And nitrites?

A. Nitrites were quite high in the Illinois at that time; the nitrites were quite high; I would not say high, but quite high, the intermediate between low and high.

Q. And the chlorines?

2702 A. The chlorines were very high.

Q. Now, from your experience and analyses as a chemist, what does high albuminoid ammonia, low free ammonia, high nitrites, and high chlorines indicate when found in water?

A. Well, they indicate pollution, but they make it uncertain what the source of that pollution might be, unless one has evidence, or has formed definite conclusions based upon some investigations, what the source of the high chlorines may be and whether or not the general character of the river from which these samples are taken indicates sewage or vegetable origin of pollution.

Q. What in the examinations of 1899 did you find the albuminoid ammonia, the free ammonia, the nitrites and the chlorines to be?

A. I found them at times quite high and at times again high, throughout; that is for 1899.

Q. Now, for albuminoid ammonia; how did you find albuminoid ammonia?

A. The albuminoid ammonia I found comparatively high in 1899.

Q. In suspension or solution?

A. I found it high in solution.

Q. And how in suspension?

2703 A. In suspension I didn't find it as high throughout as I did in solution.

Q. But it was high in suspension, was it not?

A. Well, at times it was high after heavy rainfalls in the

Illinois River valley, both of the ammonias would go up, and of course the albuminoid ammonia would go up with the free ammonia and show high figures.

Q. No, I mean in suspension and solution.

A. Yes, the albuminoid ammonia in suspension would show an increase as well as in solution after the rain-falls.

Q. In 1899 you found then the albuminoid ammonia high, both in solution and in suspension?

A. Well, at times I would always find the albuminoid ammonia in solution high throughout, but the albuminoid ammonia in suspension, I would very often find less than the albuminoid ammonia in solution, but sometimes higher.

Q. That is not what I mean, doctor. You don't get my idea. You found the albuminoid ammonia in suspension as compared with the albuminoid ammonia in solution lower than the albuminoid in solution?

A. Yes, sir.

Q. But the albuminoid ammonia that you found in suspension was high, too—a high degree wasn't it?

A. Sometimes, yes.

2704 Q. Aside from being compared with that in suspension?

A. Sometimes it would be high but for most of the time the albuminoid ammonia in solution would be higher.

Q. Yes, woud be higher?

A. Yes.

Q. But I mean without comparing it with the albuminoid ammonia in solution, just taking it in suspension, wasn't it always high?

A. No, sir; it would be comparatively low sometimes.

Q. Now, how about the albuminoid?

A. You see the total solids would show lower results, that is the water would not be so turbid, and there would be less matter in suspension present, and accordingly less albuminoid ammonia in suspension, because the albuminoid ammonia there would only represent the albuminoid ammonia in the suspended matter—principally of vegetable character then.

Q. How was the free ammonia?

A. In 1899?

Q. Yes.

A. Well, free ammonia—

MR. WOERNER: Are you talking about this one sample now?

MR. TODD: No, the series of samples; the investigation of 1899.

A. During 1899 I found sometimes the free ammonia low
2705 in the Illinois River and then again I would find it high.

Q. And the nitrites?

A. The nitrites the same way, I would find them low at times and then again quite high.

Q. And the chlorines?

A. The chlorines I found pretty high in 1899.

Q. From that analyses you concluded that the Illinois River as it enters the Mississippi was a sewage contaminated stream, did you not, and the waters were not potable?

A. I did, taking into consideration the reports of Professor Long and Professor Palmer, as to the condition of the entire Illinois River valley.

Q. Yes, taking into consideration all the information that you had at hand, you concluded that in 1899 the Illinois River was a sewage polluted stream, did you not?

A. Yes, sir.

Q. And was not potable water?

A. Yes.

Q. After the waters of the Drainage Canal leave the Bear Trap Dam at Lockport, do you know into what it empties, after going over the watershed of the Desplaines River?

A. Well, it empties at Lockport into the Desplaines River.

Q. And from the Desplaines River is there any lake through which the Desplaines River runs?

2706 A. Well, I understand that there are larger basins through which the Desplaines River runs there, that are termed by some people, lakes.

Q. Are you acquainted with what is known as Lake Joliet, immediately south of Joliet, along the line of the Desplaines River about eight miles from Brandon Road?

A. No, sir; I have not been there.

Q. Have you read anything of it, or have you any knowledge about the existence of Lake Joliet?

A. I have read something about it.

Q. Now, when the sewage waters of the Desplaines River run into Lake Joliet, what effect would that have upon the purification and oxidation of that sewage?

A. Well, that would depend upon the character of that lake. If it were a lake where there is no flow of water at all, that would practically be in a quiescent state, as far as motion towards one direction is concerned, because absolutely quiescent would not be proper to assume, because the water conditions and the winds will produce motion there; but what I mean, motion of flow in one direction—if that would not be the case, if it would be what we usually call the quiescent state it would enable the oxidation processes somewhat by sedimentation of the suspended matter and the sewage at the bottom of the lake, but if this lake were simply a large basin in the course 2707 of the river, and there would be a current through that lake, of course this sedimentation would not take place to that extent, and the faster that current would be passing through that lake, of course the less sedimentation there would be and the stage of the water would have to be taken into consideration also, at low stage of course the current would be less. There would be more sedimentation taking place than there would at the rapid flow of the current.

Q. If Lake Joliet was two or three miles in length and from one-half mile to a mile in width, with a kind of a peat bottom bogs, and the waters passing through would disseminate themselves throughout the lake and would only leave a slow current through the lake, would not that act as a sediment basin for the waters of the Desplaines River?

A. It would somewhat, and the slower that current would be the more sedimentation would take place, and the faster the current would be the less sedimentation.

Q. A great proportion of the sewage going through a lake of that character would have a tendency to be deposited on the bottom of this lake or morass, as it were?

A. Yes, sir.

Q. And fermentative changes would operate in a lake of that character, would it not?

A. Yes, sir.

2708 Q. Now, if it should appear, doctor, that before getting to Lake Joliet there was considerable—quite a number of acres of land over which the waters of the Desplaines flowed, sedimentation would take place under those conditions the same as it would in the lake, would it not?

A. Yes, if the current were very slow, and these low-lands would retain any of the sewage that had been during the overflow deposited on the banks. If such conditions would prevail these fermentative changes would be facilitated somewhat.

Q. While the waters were over the land would sedimentation be the only method of purification?

A. Well, since sedimentation would be one of the material forces of nature, that would bring about various stages of what we call purification.

A. And in Lake Joliet, where the sewage laden waters of the Desplaines River enter, wouldn't that lake operate as a septic tank to some degree?

A. It would if the ordinary conditions that are requisite for a septic tank would prevail there, as I said, slow flow and an abundance of an-aerobic bacteria to perform the initial process of purification.

Q. What current would you call a slow current, doctor, through a lake of that character?

A. Well, I would consider a slow current a current that 2709 would perhaps have one-eighth or one-fourth of a mile flow per hour.

Q. If the current should be as high as half a mile an hour what effect would that have?

A. That would have some effect in facilitating sedimentation.

Q. Now, after the waters left Lake Joliet and on their way down to the Illinois River, if it should appear that thousands of acres of land were inundated, low-lands, over which this water in its course traversed, what effect would that have upon the purification of the sewage laden waters of the Desplaines River?

A. It would have some effect in distributing the sewage over vast fields there, during the overflow, and if the sewage would have some time there to remain in a quiescent state some fermentative changes would take place in the ordinary process of purification.

Q. And if after traversing over these many acres of land that were inundated, it finally empties into the Illionis River where it continuously overflows the banks of the stream in high water, would not that condition of purification obtain constantly?

Q. It would be facilitated whenever conditions of inundation of large areas of land would prevail.

2710 Q. Do you know what the conditions are through which the Desplaines River runs from Joliet to LaSalle, on the Illinois?

A. Well, I am familiar with the conditions somewhat.

Q. Have you any idea of the number of acres of low land between those points that the sewage laden waters of the drainage canal runs over in arriving at LaSalle?

A. No, sir; I have no data to that effect.

Q. Have you any idea or any information of any kind in regard to those conditions?

A. I have nothing definite in that direction.

Q. Don't you think that in order to properly consider this question intelligently, that data of that character is essential?

A. No, sir.

Q. Is it not as essential to know in the Illinois River as in the Missouri?

A. It is a matter of analytical investigation as far as the character of that water is concerned, in considering the question of sewage pollution of those rivers, and if the analytical results show high figures at various points along the route that the river is traversing, it would be the most important information, and if found consecutively along the entire route it
2711 would justify general conclusions as to the character of that water chemically.

Q. Wouldn't it be essential, doctor, as essential in ascertaining the origin of contamination as to whether from vegetable or animal, to know these conditions obtaining in the Illinois River between LaSalle and Lockport?

A. It is not necessary when the analytical data from the samples taken along the route demonstrate high pollution, because the object of the analytical investigation is only to ascertain the character of that water as it flows along that route.

Q. Have you not repeatedly stated in your examination, doctor, that the analytical data, in the absence of knowledge as to the source from whence pollution came, was not sufficient to enable you to determine whether it was sewage or animal pollution?

A. The source, yes, of the pollution as estimated in the analyses of the samples.

Q. And have you not stated that large areas of overflowed land eliminated sewage contaminaton from waters?

A. I said that it may do so under certain conditions.

Q. And is it not necessary to ascertain whether those conditions exist or not before drawing a conclusion as to whether the elimination or the presence of the chemical constituents of the water are attributable to animal or vegetable
2712 origin?

A. If the analytical results uniformly show high impurities along the route of a river, there are various questions that come into consideration, such as the original source of that pollution, the relative proportion of pollution that might come from tributaries, the relative proportion of pollution that might come from large cities that discharge their sewage into that river. Those questions of primary importance would be considered and in explanation of the origin of the pollution if the chemical analyses enable an approximate distinction between vegetable and animal origin of the organic matter, it would be sufficient to form final conclusions on the character of that water as it traverses the route of the river.

Q. Did you ascertain all those conditions that you have enumerated?

A. In application to what investigation do you mean?

Q. The Illinois river?

A. Illinois river, you mean after the opening of the Drainage Canal?

Q. Yes?

A. Yes, sir.

Q. What tributaries of the Illinois River did you investigate for sewage pollutions?

A. I investigated practically all the tributaries that may
2713 come into consideration in determining that question.

Q. What tributaries did you investigate, doctor?

A. I investigated the Kankakee, the Sangamon, the Fox River, and several others.

Q. What are they?

A. Well, they are tributaries of the Illinois River.

Q. Well, just name the rivers—all the rivers that you investigated?

A. I would have to refer to my data to look that up.

Q. Well, will you please refer to it?

A. Yes, sir. The Kankakee, the Fox, River, the Big Vermillion, the Sangamon and the Spoon, that's all.

Q. Did you examine the Mazon?

A. Yes, sir, the Mazon. I overlooked that.

Q. The Macoupin creek?

A. I think at the time of the consideration of this problem of the tributaries of the Illinois, that I did consider Macoupin creek.

Q. The Mackinaw?

A. No, I don't recollect at this instant.

Q. The Quiver?

A. I think I did, yes, sir; the Quiver.

Q. What examinations of the sewage did you make of these different streams, doctor?

2714 A. I didn't make any analytical investigations of my own, because I found analytical data published by responsible authorities, by Professor Long and Professor Palmer, that could be taken as a fair criterion for the character of these rivers, and also a report published by Lyman E. Cooley in 1890, entitled "The Lakes and Gulf Waterway, as Related to the Chicago Sanitary Problem."

Q. What effect would it have upon the waters of the Illinois River when it enters at LaSalle—are you familiar with the conditions of the water at LaSalle?

A. I am from an examination of samples taken at that point.

Q. I mean the condition of the River Desplaines there, doctor?

A. Not from my own personal observation on the spot. I have not been there.

Q. Have you information as to the effect that there is a large stagnant pool in excess of a mile, right under the hill at LaSalle, along LaSalle, where the waters of the Illinois river—

A. I understand that is the case, yes, sir.

Q. What effect does that have upon the waters of the Illinois river as to purification?

2715 A. Well, if the Illinois river there would stop its flow completely and enable sedimentation by the stagnant condition of the river there, fermentative changes producing initial purification would certainly be facilitated.

Q. Have you any idea, doctor, how many thousands of acres of land in the form of marshes are along the course of the Illinois river?

A. No, sir.

Q. Have you ever tried to ascertain that data?

A. I have. I have studied all the reports that are published that came to my notice and that I can find on the subject.

Q. Are you aware that there are many thousands of acres of land that is inundated by the Desplaines and the Illinois rivers before the waters get to Peoria?

A. I understand that inundations take place at times of overflow.

Q. Well, during those times, would the same conditions of purification and sedimentation take place in these overflowed lands, as would take place along the shore of the Missouri river?

A. They would if all conditions were alike in both rivers.

Q. What conditions, doctor?

2716 A. Well, first of all the chemical character of that water carrying the sewage. The quantity of the sewage in that water in proportion to the quantity of water with which it is mixed, the weather conditions and several other conditions as I have explained them before, which would facilitate the fermentative initial purification process.

Q. During these times of overflow that would have a tendency to purify the waters wouldn't it to a considerable extent, depending upon the amount of territory that is overflowed?

A. The sewage would be distributed over large areas of land like that during the overflow. If that sewage would have a considerable time to remain in a more or less quiescent state on those lands, it stands to reason that it would undergo fermentative changes of initial purification. That part of the sewage, however, that would remain in the channel, that part of the sewage would not be similarly affected.

Q. Wouldn't the water become impregnated with vegetable contamination in going over the overflowed marshes of Illinois?

A. Certainly, that part of the water that would overflow those large areas of land, that would be impregnated with vegetable matter.

Q. And what it would lose in sewage pollution, it would gain from vegetable pollution to a certain amount, wouldn't it?

A. Yes, if that land had vegetation, it would necessarily receive accessions from that source.

Q. And vegetable pollution would manifest itself in the
2717 presence of albuminoid ammonia, wouldn't it?

A. Yes, and also in the color of the water, and sometimes as found in the odor of the water.

Q. Now when the water gets to Peoria, do you know whether it flows through Lake Peoria before arriving at Peoria, or after it leaves Peoria—do you know where Lake Peoria is located?

A. Yes sir.

Q. Where?

A. Lake Peoria is located above.

Q. Now when the waters pass into Lake Peoria after coming the distance from Chicago over vast swamps or marshes along its route, through different lakes, and stagnant pools, Lake Peoria would continue the fermentative changes and oxidations of that sewage water, wouldn't it, if any remained?

A. More or less, yes, dependent upon the size of that lake, dependent upon the question whether there is a flow in that lake, any current carrying the water through the lake rapidly and so forth.

Q. Did you make any investigations to ascertain the dimensions of Lake Peoria?

A. No sir.

Q. How large a lake is Lake Peoria?

A. Well, I couldn't tell you now, I only know that it
2718 varies very much in its size, and I haven't got any data at hand just now as to the size of that lake at those various times.

Q. Have you any information?

A. I have some information about that so-called lake.

Q. About how large is it, doctor?

A. Well I couldn't tell you at this moment; it is some time since I have studied that data.

Q. How swift is the current through Lake Peoria?

A. I couldn't tell you at this moment; I have no data at hand.

Q. Do you know the source of the Kankakee River?

A. No.

Q. Have you ever heard of the Kankakee Marshes of Illinois?

A. I know of those marshes from the literature published on the subject.

Q. If it should appear that those marshes drain into the Kankakee river, would not the Kankakee river carry into the Illinois large quantities of pollution due to vegetable origin?

A. Yes, at times of very high water in the Kankakee they would.

Q. Didn't you deem it necessary in arriving at your conclusions above Peoria, to ascertain the length, breadth, depth and current in Lake Peoria?

2719 A. Well, I did inform myself on that subject a lon
time ago; it is several years ago that I investigated that problem and I have been compelled to remember a great deal of data so I cannot just now summon to my memory those data, but the data—at the time of the investigation, I knew what the dimensions of that lake usually and at high water and low water were.

Q. Don't you deem it a matter of considerable importance to know the number of acres of land in the form of marshes that the waters of the Illinois commingle with and overflow before arriving at Peoria?

A. Yes sir.

Q. Did you ascertain that information?

A. I tried to obtain all the information from available data published.

Q. Well, did you get any specific information in regard to the number of acres along the Illinois river that was overflowing marshes, or farms lands?

A. No sir, except that there are general conditions which I familiarized myself with from the literature published on the subject.

Q. Is Copperas Creek located above or below Peoria?

JUDGE JOHNS: Copperas Creek is about 25 miles below Peoria?

MR. TODD: The dam at Henry is located above Peoria, isn't it?

2720 A. Yes sir.

Q. Doesn't that dam create a stagnant pool of water in the Illinois river?

A. At times the flow is very much retarded at that dam as well as at the other four principal dams which are located in the Illinois river, yes sir.

Q. The retarding of the flow of water at those places serves to elevate the water and back it up-stream, doesn't it?

A. Yes sir.

Q. And overflow the banks of the river?

A. Yes sir.

Q. And on each side of the river at those places the land is low, isn't it?

A. Yes sir.

Q. And thousands of acres of land is inundated by virture of those dams?

A. Yes sir.

Q. Doesn't that condition act as a septic tank for the waters of the Illinois when it is backed up there and held by those dams?

A. In a measure it would, yes.

Q. Did you in your examinations endeavor to ascertain in what measure and to what extent purification would take
2721 place at those points?

A. Yes sir.

Q. And were you able to tell?

A. I think I was able to judge from the analytical results of the samples taken along the route, what effect the dams would have in the ordinary purification processes of the sewage in the water, yes.

Q. And did it have a beneficial effect?

A. I think that at times during the year some effect is due to those dams in purifying these waters of the Illinois river to some extent.

Q. In what seasons of the year is that effect more marked, in winter or summer?

A. Well, that effect would be prevalent during the low water stages of the year, after the overflow had taken place, carrying the sewage laden water over those fields; that is at the low water stage that part of the sewage that would remain on those fields would not be swept back into the river and of course the low water stages then would facilitate the purification processes.

Q. The low water stages of the Illinois river are mainly in the summer months, are they not?

A. Well sometimes, if the season is dry and if the rainfall is low.

2722 Q. Well it never is as high in the summer as it is in the spring.

A. It is usually high, during the spring freshets, yes.

Q. The spring freshet is when the snows in the watershed of the Illinois and its tributaries begin to melt and come down the river in the shape of water?

A. Yes sir.

Q. During those times there is greater dilution to this sewage water than in the summer, isn't there?

A. Dilution of the chlorines, yes.

Q. And dilution of the sewage?

A. Well, the analytical results of many investigators demonstrate that the freshet doesn't result in the decrease of ammonia for instance. The ammonias go up after a freshet, because a freshet will sweep out the ammonia which is prevalent in the sediment at the bottom of the river, where, during the low stages these fermentative changes are going on, then that sludge is swept out and my investigations show that while the chlorine will be lowered and the dilution evidently reduces the figures of chlorine materially after the freshet, the ammonias go up.

Q. Isn't the presence of ammonias in freshets due largely to the manure of cattle, and the farm houses and stables 2723 that are being washed down into the creeks and tributaries of the river throughout a great expanse of country and emptying directly into the Illinois river?

A. To a certain extent, yes, but they are also due to the sewage that may have been in that river before these freshets come, and due to the ammonias themselves prevalent at the bottom of the river where the fermentative changes in the sludge at the bottom of the river are going on and the ammonias is produced; then they may be due to the ammonia in the rain water, and may be due to the ammonia in the snow that melts and particularly to snow that has fallen in the neighborhood of cities, which is apt to contain free ammonia. I speak now of free ammonia and also rain-water. Rainwater may add free ammonia to river water in heavy rain-falls, spring freshets.

Q. In the country, doctor, where a great many cattle are being fattened for the markets along the sides of creeks for watering purposes, and a heavy rain comes up generally through the country, doesn't that wash down the refuse of those cattle on the different farms covering great expanses of territory?

A. You mean through the tributaries?

Q. Through the tributaries which ultimately empty into the river and cause it to rise; doesn't that account for the presence of ammonia?

2724 A. Yes, some, but not much, because this manure undergoes initial processes to some extent, before it reaches those brooks and tributaries, for the same reason that it is to a large extent surface drainage, and the soil there acts as a filter, and the nitrifying bacteria in the soil will naturally assist very much in the purification processes of manure from farms and from the cattle yards of farms, etc. So that when that water reaches the rivers, when the water that drains through this soil first reaches these branches of the rivers, it is in an advanced state of purification. It don't show such high ammonia because ammonia is always the preliminary state of purification, the first product.

Q. Does the high dilution have any effect upon the sewage in water?

A. High dilution has a great effect on the chlorines, in reducing the chlorines in water.

Q. Has it an effect upon anything else in the water except on the chlorines?

A. Well, it may have some effect on the nitrates and nitrites in reducing their quantity.

Q. Does it have any effect in lessening the quantity of albuminoid ammonia, high dilution ?

A. Well now, in some instances it may and in some instances it may not, because if the water that enters the
2725 river there and dilutes the albuminoid ammonia; if that water is of good character naturally the albuminoid ammonia will have been reduced in total quantity because it is diluted, but if that water contains albuminoid ammonia of vegetable origin, as is frequently the case, after a freshet, why then the albuminoid ammonia may go up very high.

Q. In arriving at a conclusion from chemical analyses of the waters above Peoria, does the current of the river cut any figure in the conclusions drawn?

A. Yes sir.

Q. During high water, there is increased dilution with a correspondingly increased current, with a correspondingly greater area of territory inundated, is that true?

A. Yes sir.

Q. Do all those elements enter into and are they essential facts to be known in drawing a conclusion as to the cause of the pollution of the waters above Peoria?

A. They may be of value, but not essential in drawing a conclusion as to the sanitary character of that water as it flows in the river.

Q. If you only had the analyses to go by and knew nothing of the conditions before mentioned, such as the area of territory inundated, the volume of dilution or the rate of the current, would you be able to draw definite conclusions
2726 from those analyses as to the source of the pollution?

A. I would. I haven't taken into consideration all those conditions.

Q. Would you be able to draw a definite conclusion from the analyses in the absence of any knowledge upon those conditions?

A. Now a conclusion as to what?

Q. As to the condition of the water and the source of its contamination, whether vegetable or animal?

A. Yes, as far as that is concerned.

Q. Take the chlorines, could you tell to what the high chlorines would be attributed in the Illinois river if you didn't know the source from which it was derived except by the analyses that were made of the waters?

A. These high chlorines and the high ammonias and the high organic matter in general found there, if accompanied by high nitrites, would suffice to enable the conclusion that the chlorine there was due to sewage pollution.

Q. Are the conditions of the Illinois any different from the conditions of the Missouri?

A. Yes sir.

Q. High chlorines in the Missouri River without knowing the source whence they come, I believe you stated yesterday or the day before, that you were unable to state whether they were from animal or mineral origin, by the analyses
2727 themselves.

A. That was with the hypothetical question, if the chlorines were high and if the nitrites were high, but only in case the general analyses point to certain conditions like they prevail in the Illinois River, with the high organic matter, high nitrites, high free ammonias, and chlorines going with that, since high ammonias and high organic matter and high nitrites would hardly go together unless there was high chlorines, indicating sewage pollution, the conclusion is justified that it is immaterial to determine the source of the chlorines in such a case. When you form an opinion of the sanitary character of the water, you take into consideration the general analytical results. You compare figures for the principal ingredients of pollution and from that comparison you form a general conclusion.

Q. Can you tell by the chlorines whether in the Illinois River they come from vegetable or animal origin?

A. Well, that would be impossible for anybody to determine as to the chlorine itself.

Q. As chlorine can you tell whether the chlorine comes from mineral or vegetable or animal origin, from the chlorine itself?

A. No sir.

Q. Can you have high albuminoid ammonia and free ammonia?

2728 A. Do you mean high or low free ammonia there?

Q. High free ammonia and high albuminoid ammonia and high nitrites from vegetable origin?

A. It is not likely.

Q. Can you have it, doctor?

A. Well, it may be possible but from the examinations I made of those rivers—

Q. I am not speaking of your examinations, doctor; I am speaking now as an abstract proposition. Can those conditions obtain in water from vegetable origin?

A. I think it does in exceptional cases, but not as a rule.

Q. Can those conditions obtain in water from animal origin?

A. Not unless they were accompanied by correspondingly high chlorines.

Q. Could those conditions obtain from vegetable origin and the high chlorines were directly attributable to salt beds?

A. Well now, what conditions do you refer to?

Q. High albuminoid ammonia, high free ammonia and high nitrites, and that the chlorine was directly attributable to mineral origin, to salt beds?

A. What would be the question then?

Q. Can you have those conditions such as is presupposed in the previous question, from vegetable contamination?

2729 A. The high chlorines would render that improbable.

Q. If they came from mineral origin?

A. No—wait a moment. If it had been determined that the chlorines came from mineral sources—

MR. WOERNER: That is what he said.

A. That then the high ammonia and high nitrites and high albuminoid ammonia might be due to vegetable origin. Is that the question?

Q. That is the question.

A. Yes, then it may be from vegetable origin if the nitrites are high, correspondingly high to the albuminoid ammonia and the free ammonia correspondingly high.

Q. Could you have low nitrites and high free ammonia and high albuminoid ammonia under the same conditions from vegetable origin, attributable to salt beds?

A. Yes, they may be of vegetable origin with high free ammonias and low nitrites, but high free ammonia.

Q. Could you have high albuminoid ammonia, low free ammonia and high nitrites with chlorine attributable to mineral origin from vegetable sources?

A. Well that is a case that would hardly occur. It may be possible, but—

Q. That is what I want to know. Could those conditions obtain?

2730 A. It would be a very rare occurrence, because in the relation of those compounds with the albuminoid ammonias high and the nitrites high, the free ammonia ought to be high because the free ammonia there is an intermediate product of the fermentative changes going on and it is not likely that there would be high albuminoid ammonia and high nitrites unless the albuminoid ammonia were high with it.

Q. Couldn't you have such a condition, is what I am asking. Is such a condition possible?

A. This is now a hypothetical question.

Q. Now are such conditions possible?

A. Well, I don't know of any from my analytical investigations.

Q. Could you have those conditions possible from animal contamination, attributing the chlorine to animal origin?

A. With the condition of high free ammonia or low free ammonia?

Q. High?

A. Those conditions that you mentioned just now, though, included low free ammonias; that is just why I said it was doubtful.

Q. I mean including high free ammonia, high albuminoid ammonia and high nitrites, with the chlorines attributable to

salt beds, could you have that condition as being derived
2731 from vegetable origin?

A. Yes, provided that the chlorine is proven to have come from salt beds.

Q. That is what I stated.

A. That may be possible in some instances but it would be an exception to the rule. It would require certain conditions that are not often found.

Q. Now when you made your analyses above Peoria, what were the conditions of the free ammonia?

A. I found the free ammonia high.

Q. What were the conditions of the albuminoid ammonia?

A. The albuminoid ammonia I found sometimes high, but at times I found them so low that they were lower than the free ammonia, which was a very bad sign.

Q. And the nitrites?

A. I found the nitrites high. Now, how far up above Peoria do you mean?

Q. At the point above Peoria that you took the samples.

A. You don't mean the entire route?

Q. No, I mean at the point above Peoria.

A. I found the nitrites high at Peoria, three miles above Peoria.

Q. And the albuminoid ammonia?

A. The albuminoid ammonia I would sometimes find
2732 quite high and sometimes find low, as compared with a
uniform high free ammonia.

Q. And when you found low albuminoid ammonia and high free ammonia, what did that indicate?

A. Low albuminoid ammonia I said, and high free ammonia.

Q. Yes?

A. If it corresponded with high nitrites and comparatively high chlorines, it indicated sewage pollution beyond a doubt.

Q. Low albuminoid ammonia and free ammonia indicated that the albuminoid ammonia had been oxidized, didn't it, and converted into free ammonia?

A. No, it showed a character of the free ammonia justifying the conclusion that it was of animal origin; that is generally assumed. That is the conclusion that is usually drawn by all sanitary chemists, that when the free ammonia is higher than the albuminoid ammonia and it comes with high nitrites and high chlorines, that is a positive indication of the prevailing animal origin of that sewage.

Q. At what point above Peoria, did you take the samples aside from the three mile point above Peoria?

A. That depends upon the time of the investigation.

Q. Any one time, doctor?

A. At one time there were samples taken at LaSalle.

2733 Q. How far is LaSalle above Peoria?

A. I couldn't tell you at this moment; I would have to look that up. I haven't got the table of those distances at hand just at this moment.

Q. Give it to me approximately, doctor. I won't bind you to your answer. Is it fifty miles?

A. Well I wouldn't say because I cannot recollect at this moment.

Q. We will pass that doctor. Did you figure or estimate the percentage of purification from Lockport to LaSalle of the waters of the sanitary canal?

A. No sir, not percentage figures.

Q. Do you know how much the sewage of the sanitary canal purifies itself by the time it gets to LaSalle, after leaving the Bear Trap Dam at Lockport?

A. The fermentative changes of the initial processes of purification of the sewage—

Q. The question is doctor, do you know?

A. I haven't made a percentage calculation of that but I know—

Q. Did you make any kind of a calculation that would enable a layman to understand how much of that sewage has been eliminated from the waters of the Drainage Canal by the time it got to LaSalle?

2734 A. That would be impossible to determine in any other way than in approximations obtained from the careful study of the analytical data because the question of elimination of sewage would practically mean the completion of the ordinary chemical purification processes, and that is almost impossible to determine in this case. The analytical data have to be compared as obtained from samples collected at points say at the drainage canal at Lockport, from the Desplaines River at LaSalle and from a comparative study of those data the conclusion is to be drawn, and the only possible conclusion that can be drawn, as to what general degree of purification may have taken place, and what changes that sewage may have undergone in transit between those two points.

Q. Did you figure out from your data those changes?

A. As I said, it was impossible to figure those data in percentages; nobody could do that.

Q. Then the effect of purification in the elimination of Chicago sewage in going from Lockport to LaSalle is an impossible calculation, is it?

A. The percentage calculation as you indicate would be impossible to perform by anybody.

Q. Is there any way of ascertaining how much sewage contamination is added to the Illinois river from other
2735 sources than the drainage canal between Lockport and LaSalle?

A. In general, yes.

Q. Did you ascertain that fact?

A. I did.

Q. How much; what percentage of sewage was added to the Desplaines and Illinois rivers before they had got to LaSalle, from sources outside of the drainage canal and the Illinois and Michigan Canal?

A. That would be difficult to estimate unless the various conditions would be taken into consideration. The analytical data obtained from the examination of the samples along that route, would give information that would enable some conclusions as to the effect of the sewage of the drainage canal on that river.

Q. Were these analytical data to which you referred quantitative?

A. Yes sir.

Q. Would they tell the quantity of sewage that was added, of the percentage of sewage in a given sample of water?

A. It would demonstrate the effect of any sewage that was

added to the waters after the drainage canal sewage was discharged into the Desplaines River. That would depend upon the places where the samples were taken; that is whether the sample was taken from the Desplaines river before the drain-
2736 age canal meets it, and the sample taken from the drainage canal before it meets the Desplaines river; then a sample after the drainage canal meets the Desplaines river; then a sample taken after the sewage of, I will say Joliet for instance, has been discharged into the river and a sample taken after that sewage has been discharged.

Q. Would that sample indicate the volume of sewage discharged from Joliet into the Canal?

A. Well, that would be impossible to determine; nobody could do that.

Q. And has that been done?

A. Not to my knowledge.

Q. Do you know how much sewage from LaSalle is discharged into the Illinois River?

A. The sewage of LaSalle would be inappreciable.

Q. That isn't what I am asking you. Do you know how much in volume?

A. I cannot recall the figure at this time, but I did study that problem.

Q. Do you know how much in volume was discharged into the Illinois River from the Sangamon?

A. Do you mean to say how much water or how much sewage?

Q. How much sewage—water isn't contaminating in itself, is it, unless it has sewage pollution?

2737 A. No. At low stages of the Sangamon River coming from that river would be inappreciable, and hardly have an effect upon the general chemical character of the Illinois River.

Q. But you don't know the amount?

A. No, but I studied analytical data obtained from analyses of the Sangamon river before it meets the Illinois river and after the two rivers have joined and from this analytical data I am justified in concluding that at certain times the effect of that sewage on the sanitary character of the Illinois river would be inappreciable.

Q. Would that be true of the Kankakee River?

A. It would be true under like conditions, yes sir.

Q. Well, does the Kankakee river contaminate the waters of the Illinois?

A. I think it does some, and at times a little, but there is always some contamination there.

Q. Always some, but is it enough to affect the potability of the stream in itself?

A. No sir, because the analyses received from those tributaries showed that those tributaries are in a much better sanitary condition than the Illinois river.

Q. Assuming that the Drainage Canal did not empty into the Illinois river, would the sewage contamination from the Kankakee and the Fox river and the Sangamon, and these 2738 other rivers contaminate the waters of the Illinois so as to render the water not potable?

A. If the chemical analyses of the water from those tributaries would demonstrate considerable sewage pollution the waters from those rivers would of necessity increase the pollution already present in the Illinois river and that would depend upon the volume of water coming down those tributaries, whether it was high stage or low stage. During times of drought, the effect of those low stages, the effect of those rivers will be very little, and the chemical analyses of those waters from the tributaries showing that they are of much better quality, although not pure, yet only polluted to a very limited degree, and this pollution by low chlorines demonstrating that there is only a little, and in such cases, if any pollution of animal origin could be deduced from those figures as obtained, I say that a pollution from those rivers would be at times so immaterial that it wouldn't affect the general sanitary character of the Illinois river injuriously, if the Illinois river had run some distance after receiving the waters from the tributaries.

Q. Do the chemical analyses of those rivers emptying into the Illinois river demonstrate the conditions that you have related?

A. They demonstrate that at times those conditions that 2739 I mentioned prevail.

Q. Then if you would eliminate from the Illinois river the sewage contamination from the sanitary district, these rivers with that minimum amount of sewage as disclosed by the chemical analyses would not render the waters of that river non-potable, would they?

A. At times, yes.

Q. At what times would these rivers pollute the waters of the Illinois, so as to make the waters of the Illinois unpotable?

A. Well, they could do so when the stages of the rivers by its tributaries would be high, because that would sweep out whatever accretions of pollution there might have been on the banks, that it would increase the ammonias. It would sweep out the deposited sludge in those rivers and that would enter the rivers. Now this would depend very much upon the character of that pollution, whether of vegetable or animal origin. I speak of pollution in general, not specifying sewage pollution.

Q. But by the time it got below Peoria, all that contamination would disappear, wouldn't it, on account of its small quantity?

A. Well, the general analytical results from those rivers, demonstrate that the pollution from those tributaries would in a measure disappear during the run of the Illinois river.

2740 Q. Now what effect would the sewage from Lockport have upon the Illinois river if the sewage of Chicago was cut off from it; wouldn't that disappear? I don't mean Lockport, I mean Joliet. Wouldn't that disappear long before it reached Grafton, the amount being so inconsiderable from Joliet?

A. I think that the Joliet sewage before it would reach the mouth of the Illinois, would be purified to an extent that the effect of the original pollution would be of a character that while the water at the mouth of the Illinois would not be pure, yet it would be in a much better condition than the water at the mouth is, because of the sewage of the drainage canal entering the Desplaines river.

Q. I am eliminating the drainage canal, doctor. I am taking conditions that are based upon the elimination of the sewage of Chicago?

A. Yes sir.

Q. Now that would be true of LaSalle and the towns located along the river there, you said LaSalle sewage was inconsiderable.

A. Yes sir.

Q. And I believe you also stated here the other day that the sewage from Peoria would be purified by the time that it got to the mouth of the Illinois river at Grafton, didn't you,
2741 if the Chicago sewage was eliminated?

A. I didn't say that. I said that if the water of the Illinois river when it reached the city of Peoria, would be pure, then I said it would be true that the sewage of the city of Peoria would chemically have undergone changes by the time it reached Grafton, to the effect that it would not be noticeable in the analytical results found in the water at Grafton, chemically speaking.

Q. I am talking chemically. You qualified the other day first you said, as a bacteriological expert and disqualified yesterday, so I want to confine you to chemistry.

A. I didn't qualify as an expert bacteriologist at any time of my testimony.

Q. I say as I understood you, not as you understood yourself. I am responsible for that, not you.

A. Yes sir.

Q. Now, eliminating the sewage of Chicago from the Illinois river, the sewage of Peoria entering that river would be not chemically discernible when it got to Grafton would it?

A. The effects of that pollution would not be chemically discernible at Grafton.

Q. Now, doctor, if your statements are properly based on investigation and if you properly state the conditions of
2742 the Illinois river and its tributaries as to pollution, will you explain to me how it was in 1899, before the opening of the Drainage Canal you reported to the Board of Health of the City of St. Louis that the waters of the Illinois river at Grafton were contaminated and not in a potable condition, as evidenced here by the report on file?

A. Because I found the water of the Illinois river above Peoria badly polluted.

Q. In 1899, before the sanitary district channel was opened you made analyses under the direction of the Board of Health and the samples that were made were 19, taken three and five miles above Grafton, and from those analyses you reported the contamination of the Illinois River?

A. Yes sir.

Q. Now my question is, if the sewages of those cities purified themselves and the tributaries of this river, the Illinois river, do not pollute the Illinois river at Grafton, chemically speaking; how is it that your analyses in 1899, before the opening of the drainage canal brought you to the conclusion of denominating that water a polluted water and not potable water?

A. Because my chemical analyses of the samples taken in the Illinois river a few miles above Grafton, demonstrated the polluted character of that river at that point, and my in-
2743 vestigation of analytical data furnished by Professor Long and Professor Palmer, also showed that the Illinois river was badly polluted a few miles above Peoria. The explanation would easily be found in the conclusions that I drew that the Illinois river was in 1899 a badly polluted stream throughout.

Q. Then if your conclusions are correct that the Illinois river was a badly polluted stream in 1899 throughout, why is it then that you conclude that the sewage of the cities along the banks and its tributaries do not contaminate the waters of that river at Grafton?

A. Because the Illinois river was badly polluted before it reached Peoria, before it passes those towns.

MR. TODD: I move to strike out the answer.

A. And simply assumes its bad character again.

Q. (Question repeated)?

A. The Illinois river could be badly polluted and yet any pollution from the tributaries and from the towns along the Illinois river could be so inappreciable that it would not materially affect the character of that river. The river in its entire course was polluted in 1899.

Q. The sewage of Chicago previous to the opening of the drainage canal did not enter the Illinois river, did it, or the Desplaines river?

2744 A. Yes sir, it did.

Q. Haven't you testified that when the sewage from the Illinois and Michigan Canal was pumped into the Desplaines river, that it had been operated upon by conditions such as a septic tank would give, and that the sewage had almost disappeared?

A. Yes, I said that the preliminary stage of purification had been greatly facilitated by the conditions prevailing in the Chicago river and in the Illinois and Michigan Canal, but I never claimed that it wasn't sewage any more when it was discharged from the Illinois and Michigan Canal into the Desplaines River and the Illinois river at LaSalle, why that is still sewage as long as it is not purified in its entirety, and has reached the final stage of nitrates.

Q. Do you hold now to the view that the pollution evidenced by your examinations in 1899, at Grafton, were attributable directly to this discharge into the Illinois and Michigan Canal by the pumping works at Bridgeport, Chicago?

A. It is my conclusion that the Illinois river was polluted by the sewage from the Illinois and Michigan Canal to some extent in 1899, certainly, and the analytical data shows that.

Q. And it manifested itself at Grafton?

A. It manifested itself at Grafton by the bad condition that the water was found to be in at Gratfon.

ADJOURNED until 2:00 P. M., Friday, April 3, 1903.

2745 Southern Hotel, St. Louis, Missouri, 2:00 P. M., Friday, April 3rd, 1903. Continuation after recess. Present, the Commissioner and same counsel as before, representing the respective parties.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for further cross-examination by Mr. Todd and testified as follows:—

Q. Doctor, previous to the opening of the Drainage Canal, what amoant of sewage entered the Desplaines river through the Illinois and Michigan Canal?

A. The amount in volume could not be estimated in any possible way, with the conditions prevailing at that place, but analytical data that are at hand on the chemical character of the water in the Illinois and Michigan Canal, prior to the opening of the drainage canal would show considerable sewage present in the canal.

Q. Are you correct in your statement that the amount of sewage emptying into the Illinois and Michigan Canal could not be estimated. Isn't the contrary true?

A. Well, the volume of sewage could not very well be
1746 estimated, but the chemical analyses can show the presence of characteristic ingredients of sewage pollution that would enable an estimate of the degree of pollution of the water in the Illinois and Michigan Canal with the sewage.

Q. Isn't it a fact that just the converse is true, that the chemical analyses did not disclose the amount of sewage, but the operation of the pumps at Bridgeport would show the exact amount of sewage that was pumped into the Illinois and Michigan Canal?

A. Well the conditions as they are in—

Q. Just answer my question doctor?

A. Well, in order to do that I would have to explain the conditions there—

Q. Answer it first and explain afterwards.

A. The conditions are such at the canal that practically the sewage in the south fork of the Chicago river is pumped into the Illinois and Michigan Canal at Bridgeport.

Q. And very many gallons a day?

A. Yes sir, it varies.

Q. And an accurate count has been kept and published of the number of gallons pumped at Bridgeport every day
2747 into the Illinois and Michigan Canal, is that not true?

A. Yes sir.

Q. And does not the amount that is pumped each day indicate the amount of sewage that enters the Illinois and Michigan Canal?

A. Yes sir, the sewage as it is discharged from the south fork of the south branch of the Chicago River.

Q. What was that amount in gallons, doctor, or cubic feet?

A. Well the amount varies, considerably; sometimes it may be 10,000 or 12,000 cubic feet per minute and other times it may be 20,000 and 30,000 and as much as 40,000 cubic feet per minute.

Q. How does the amount of sewage pumped in the Illinois and Michigan Canal compare with the amount of sewage from Kansas City, Missouri at that time?

A. Well that I could not tell off-hand without making computations on the volume of sewage discharged from Kansas City into the Missouri River.

Q. What would be your opinion as to whether it would be more or less?

A. Well, that I could not tell off-hand without—

Q. You have no information on the subject?

A. Well, I could form an opinion from conclusions made with customary computations of the relative figures of water supply and sewage of Kansas City.

2748 Q. At present you have no idea as to the volume of the sewage?

A. Well, I could not form an opinion off-hand.

Q. Can you give any explanation, doctor, as to why the sewage of Kansas City, or the sewage contaminated waters from Kansas City entering the Missouri River are purified by the time they get to Fort Bellefontaine, and that this sewage emptying into the Illinois and Michigan Canal undergoing fermentative processes such as would prevail in the Illinois and Michigan Canal, is not completely purified by the time it gets to Grafton, in the Illinois River, previous to the opening of the Drainage Canal?

A. Well, that is a rather sweeping question to ask, because a comparison between the two would have to be based upon like conditions prevailing at both places, which is not the case.

Q. So that the conditions of the Missouri River from Kansas City to Fort Bellefontaine are so entirely different from the Illinois River from Lockport to Grafton, that no comparison can be made?

A. The conditions are so different as to render a comparison difficult. I don't say it is impossible after carefully computing all the data that are at hand, and on the relative proportion of sewage to water supply, and the character of the sewage of the two places, and the water with which the sewage is mixed at the two places. 2749

Q. What is your opinion based upon, your knowledge of the conditions prevailing in the Illinois River prior to the opening of the drainage canal, based upon your knowledge of the influences of a septic tank upon sewage, and conditions prevailing in the Illinois and Michigan Canal, from Bridgeport to where the same empties into the Des Plaines River, as to whether that sewage becomes purified in entering the Illinois River before it reaches Grafton or not, prior to the opening of the Drainage Canal?

A. Well that is a very long question. I would like to have it re-read to me slowly.

Q. (Question read).

A. The conditions prevailing in the south fork of the south branch of the Chicago River which is principally the feeder of the Illinois and Michigan Canal; furthermore the conditions prevailing in the Illinois and Michigan Canal are such during the major part of the year that the preliminary fermentative processes of purification of sewage are facilitated in that river as well as in the Illinois and Michigan canal; yet the sewage, although in its ordinary course of purification, partly purified in its preliminary stage, yet this sewage requires considerable additional purification, the ordinary chemical processes obtaining in this purification process, that it will require 2750 considerable time before the effects of this pollution on the Illinois River, could disappear.

Q. Well, assuming all that, will it disappear by the time it gets to Grafton?

A. It is my opinion that it does not.

Q. Does that volume of sewage unoxidized, equal the amount of sewage when it gets to Peoria that is discharged into the Illinois River by the city of Peoria?

A. The chemical analyses of samples of water taken at those points are the only data that could be used in determining that question.

Q. Did you ever take any samples of the Illinois River at Peoria before the opening of the Drainage Canal?

A. No sir, I did not.

Q. Then if you did not take any samples, how are you able to express an opinion that it does not?

A. Because there are data of responsible investigators at hand showing the chemical character of the Illinois River at Peoria, that enable conclusions.

Q. Why is it that the sewage from Chicago prior to the opening of the Drainage Canal would not purify itself in running 350 odd miles when the sewage from Peoria does in going less than 150 miles?

2751 A. First of all, I don't concede that the sewage from Peoria purifies itself from a general hygienic standpoint during that distance.

Q. Do you assert as a scientific fact that it does not purify itself?

A. I only assert that the effects of the pollution of the Illinois River from sewage of Peoria—the effects are not discernible in the chemical analyses as far as chemistry is concerned, from the samples collected at Grafton, several miles above the mouth of the Illinois—as far as chemistry is concerned.

Q. If that is true doctor, what you have just stated, can you determine whether the sewage which you found at Grafton is Chicago sewage or sewage from Peoria?

A. The fact that the—

Q. Answer my question doctor, Yes or No.

(Question read).

A. I can draw the conclusion from analytical data—

MR. TODD: Wait a minute. I move to strike out the answer and ask for a specific answer to my question.

A. Well, the answer—

MR. JEFFRIES: Read the question again.

Q. (Question read.)

2752 A. It can only be ascertained what the effect of the discharge of Peoria sewage into the Illinois River is on the sanitary character of the Illinois River; that is the only thing that can be ascertained.

MR. TODD: I move to strike out the answer and ask for a specific answer to my question.

(Question read) My question is, can you determine?

A. The conclusion is justified that since the chemical analyses of the samples of water taken at a point a few miles above Peoria, the chemical character shows certain conditions of the Illinois River at that point, that after the introduction of the Peoria sewage into the Illinois River, before the Illinois River reaches Grafton, the chemical character of the water at Grafton is of a certain character, comparing that character with the character found in the water above Peoria, the conclusion is justified that the effect of the Peoria sewage on the Illinois River has disappeared, and the general pollution of the Illinois River as established above Peoria continues in a measure to the mouth.

MR. TODD: I move to strike out the answer and ask for a specific answer to my question.

A. Well that is the only way that question can be answered.

Q. Read the question. (Question read). Now can you determine by your analyses at Grafton—if what you stated before is true,—Chicago as distinct from Peoria sewage?

2753 A. That could not be done. Nobody could do that.

Q. And that includes yourself, does it?

A. Yes sir.

Q. You made examinations of the waters above Peoria, did you not, doctor?

A. Yes sir.

Q. Suppose that the sewage of Peoria did not empty into the Illinois River, would the conditions that you found above Peoria of sewage, become better in going as far as Grafton?

A. Well that question would be hard to answer because it would depend upon various conditions that have to be taken into consideration.

Q. Doctor, have you any prejudice against answering a question of that kind?

A. No sir.

Q. Is there any reason that suggests itself to your mind, why you cannot answer that question as to whether the sewage above Peoria in the water, if the Peoria sewage was eliminated would not become purified or improved by the time it got to Grafton, going 139 miles, I believe?

A. Since there is no such condition as you state, prevailing in the Illinois River, I could not base any conclusions on actual conditions there.

Q. I asume these conditions to be true, and you being 2754 an expert I desire to have you address yourself to the assumed conditions. If Peoria did not empty any sewage into the Illinois River, would the condition of the water as you find it from chemical analyses above Peoria be improved by the time that water got down to Grafton—chemically speaking?

A. Well that is a strictly hypothetical problem.

Q. Yes sir, have you any opinion upon it?

A. Hypothetically I would then say that since the Illinois River showed such high pollution during its route from La Salle to Peoria, and this high pollution being found throughout all our investigations, that while the absence of sewage from Peoria might reduce that figure, it is my opinion now, hypothetically,—that the pollution of the Illinois River without the addition of the pollution from Peoria would prevail to a sufficient extent to still render that water as found a few miles above the mouth of the Illinois, unpotable.

Q. Would it be to such an extent, to the same degree under those conditions as it would if supplemented by the sewage of Peoria?

A. Well, I have already answered that question; that I said that while there might be less of pollution noticable at the mouth of the Illinois River, in the absence of pollution from Peoria, that still the pollution of the upper Illinois, be- 2755 fore it reaches Peoria being uniformly high, as found throughout all our investigations, this pollution would still prevail to a certain extent at the mouth of the Illinois, rendering the water of the Illinois River at its mouth unpotable.

MR. WOERNER: Now what he asked you was whether it would be just the same or not; that is what he asked you. Now answer that Yes or No.

A. Well that is impossible to say. I said there might be less pollution, but the character of the Illinois River before it reaches Peoria being such a bad pollution, its character in a measure would continue down to the mouth of the Illinois, but hypothetically—

MR. TODD: If the pollution above Peoria was eliminated would the waters at Grafton be purified of the sewage of Peoria by the time it arrived at Grafton?

A. As I have already testified, if the Illinois River water before it reached Peoria would be pure chemically, the effect of the pollution of Peoria sewage in the Illinois River would not be discernible at Grafton.

Q. In 1899, prior to the opening of the Drainage Canal you stated in your report to the Board of Health, that the waters of the Illinois River were polluted and non-potable; is that correct, doctor?

A. Yes sir.

2756 Q. To what did you attribute—

A. One moment, I did not exactly say non-potable, but I said that they were polluted; the water was polluted.

Q. Well, were they potable at that time?

A. Well, this investigation only covered a few months and during that time the character of the Illinois River water varied considerably at the mouth; that is, there were some samples taken there from the Illinois River at Grafton in 1899 that showed low results for some ingredients of pollution, whereas on other days of those nineteen collections the Illinois River water was badly polluted at Grafton, Illinois.

Q. Well, from the examinations and the sources of information that you had at hand, you concluded did you not, that the Illinois River was a polluted stream, prior to the opening of the drainage canal?

A. Yes sir.

Q. Now to what was that pollution attributable?

A. I attributed that pollution to sewage pollution from the Illinois and Michigan Canal.

Q. To anything else?

A. Well, nobody could draw that sweeping conclusion that it would not be attributable to anything else, because the pollution might be caused at that time in the tributaries—if the tributaries contributed some pollution to the river,—
2757 particularly to those rivers.

Q. Well, did the tributaries contribute any pollution to the rivers?

A. That I did not investigate for 1899; I had no data to that effect.

Q. Well, what is your opinion now as an expert as to whether the tributaries at the present time contribute any pollution to the Illinois River?

A. Well, that would depend upon the stages of the tributaries. As I have testified before, when the stages of the tributaries are low, the pollution from those tributaries is inappreciable.

Q. Well, when they are high, is it appreciable at Grafton?

A. It may be possible that at times, when the tributaries are very high and they sweep out considerable pollution that has accumulated in the course of the tributaries, they sweep it out; that that pollution may have some influence in increasing the pollution found at Grafton, but I testified before, that the low chlorines in those tributaries prevailingly show and the chemical analyses of the tributaries as performed by Professors Long and Palmer, show that the character of the pollution from those tributaries is of a different kind than the prevailingly—than the pollution coming straight down the Illinois River.

Q. Do you know, doctor, whether the sewage unconverted,
2758 that emptied into the Des Plaines River from the Illinois and Michigan Canal exceeded in volume and in quantity all the other sewage from the tributaries and from the cities along the banks of the Illinois River between Lockport and Grafton?

A. Well that would require a careful—

Q. The question is, do you know?

A. Estimation of the volumes of flow of all the tributaries; the volume of flow in the Illinois River—

MR. WOERNER: Just say Yes or No, whether you know it or not, doctor?

A. No, not off-hand.

Q. MR. TODD: Have you ever investigated to find out whether the amount of sewage unoxidized that emptied into the Des Plaines river from the Illinois and Michigan Canal was greater or less than the sewage of the Illinois River derived from all its tributaries and the cities lying upon its banks?

A. That is impossible for anybody to estimate. You speak of unoxidized sewage, the sewage—

Q. I am speaking of the sewage that enters the Des Plaines river from the Illinois and Michigan Canal.

A. Well, the sewage that enters the Des Plaines River—well, that is where it crosses the Des Plaines River at Joliet, you mean?

Q. Yes, as it comes out of the Illinois and Michigan Canal?

2759 A. Well, you know the Illinois and Michigan Canal
crosses the Des Plaines River in Joliet and then runs straight from the Des Plaines river down to La Salle, where it empties into the Illinois River.

Q. Yes, I am including that.

A. Now which point do you mean?

Q. Both points.

A. Both points?

Q. Taking the sewage, that is—sewage unoxidized when it enters the Des Plaines river or the Illinois River. Do you know whether that amount of Chicago sewage, when it entered the Des Plaines and Illinois Rivers exceeded in volume the entire sewage of all the other cities and sections of the country that drain into the Illinois River?

A. At very low stages——

Q. Do you know, I ask?

A. Well, to—

Q. Whether it is greater or smaller?

A. To say that, accurate estimations would have to be made for certain periods.

Q. Well for a year, say, do you know?

A. No, I mean for certain times, at low water stages, very low water stages, on record, I think that that sewage coming
from the Illinois and Michigan Canal would be larger than
2760 from the tributaries and from those small cities along
the route.

Q. Has the stage of water anything to do with the volume of sewage?

A. Well, in measuring or in estimating whether the quantities of sewage there in those rivers, you have got to take the volume of water into consideration because they mix.

Q. If a pound of fecal discharged is placed in 100 gallons of water, would you have any more sewage out of 100 gallons than you would if a pound was placed in 50 gallons of water?

A. Well, the chemical analyses would show a different analytical result and consequently a difference in the chemical character of those two sewages there after being mixed with so much water.

Q. Then the chemical analyses would show more sewage in 100 barrels of water than it would in 50 barrels of water, would it?

A. Well, it would show a larger volume of sewage polluting water, that is all.

Q: I am not talking about volume of sewage polluted water doctor. I am talking about the sewage that pollutes the water. Have you got the distinction?

A. Yes sir, if you take—

Q. Now do you know whether the quantity of sewage that pollutes water, that enters the Des Plaines and Illinois 2761 rivers from the Illinois and Michigan Canal, was greater or less than the amount of sewage entering into and polluting the waters of the Illinois from its tributaries and the cities nestling along its banks?

A. That depends upon the stages of the river.

Q. Would the stages of the river indicate whether you know it or not?

A. The stages of the river would have to be taken into consideration in determining that point.

Q. If the river was two feet above its normal stage, would you know?

A. It would simply mean——

Q. Answer my question, doctor?

A. It would simply mean so much more dilution of that sewage.

Q. But would you know if it were two feet above, or two feet below datum?

A. The chemical analysis would give me some information in that respect.

Q. I am not speaking about chemical analyses; I want to know if your knowledge of the subject depends upon the height or the depth of the water in the river?

A. It depends above all upon the chemical analyses of that water; the character of the water.

2762 Q. Is there any connection between the volume of the water and the source of your information in regard to that matter?

A. Well, if I want to draw any conclusions—

Q. I don't want any conclusions; I want to know whether you know or not?

A. Well, such a question could not be answered without taking into consideration the volume of the water into which the sewage is discharged.

Q. Then you assert as a positive fact that unless you know the volume of water, you can't tell whether a thousand pounds of sewage polluting substance enter the water at the Illinois River from the Illinois and Michigan Canal, or whether 500 pounds enter it from its tributaries, and cities outside of that source of pollution?

A. It would certainly require the consideration of the volume of water in that river.

Q. Doctor, isn't it a fact that volume of water hasn't a thing to do with it?

A. It has a great deal to do with it.

Q. Isn't it a fact that the effect of sewage upon water depends upon the amount of sewage in the water?

A. Certainly, and the amount of the water into which it is discharged.

2763 Q. Isn't it a fact that 100 pounds of sewage contaminating substance entering a thousand gallons of water has no effect upon whether it is 100 pounds or not?

A. Well, if we analyzed the original sewage and analyzed the mixture of the sewage in the water, you will get entirely different results, which shows to you that the water, that the volume of water with which that sewage is mixed is an important factor.

Q. Does it effect the amount of sewage discharged from the city of Chicage whether the Drainage Board discharged 200,000 cubic feet of water over Bear Trap Dam or a million cubic feet of water over the Bear Trap Dam?

A. Yes sir, it is an important factor.

Q. Does it effect the volume of sewage? Doesn't it only go to the dilution of the sewage?

A. Well, but with so much water different chemical conditions are produced.

Q. I am not talking about chemical conditions now, doctor.

A. According to the quantity of water added to it.

Q. Doesn't that sewage exist before the chemist attempts to make his analysis?

A. But he cannot take that sewage out of the water there and separate it again after it was once mixed with the water.

2764 Q. That is true, but he can control the amount of water that goes into the sewage, can't he?

A. Well how do you mean, whether he can control that amount of water that goes into the sewage?

Q. Suppose that the city water department instead of using 60 gallons of water a day only used 10; that ten gallons would be polluted with the same amount of sewage that the 60 gallons would be polluted with, wouldn't it?

A. The 60 gallons of water would produce an entirely different mixture than ten gallons would.

Q. That is true, but it would not increase the sewage that enters into the mixtare, would it?

A. No, but in estimating the effect of the sewage there, you will get a different analytical result.

Q. I am not asking for analytical results or effects. Do you know whether the amount of sewage—eliminating the water, —of the organic matter that composes sewage—I withdraw that question and will ask you one more.

Q. What is sewage?

A. Sewage is usually defined as the liquid contents of sewers, but since the contents of sewers are largely composed of solid matter,—suspended matter, as we call it too, that would have to be included.

Q. Can you ascertain the solids in sewage?

A. Yes sir.

2765 Can you eliminate the water and ascertain the solids in sewage?

A. Well, there are certain chemical processes that have to be observed there in order to determine the solids.

Q. Are those chemical processes in the solids?

A. Well all these chemical processes that determine the solids.

Q. Suppose that you take a pint of sewage and evaporate it down to the solids, and then add a pint of water to that product that you have would that put it back in the same condition it was when you first started?

A. No sir, it would not.

Q. What would be lost?

A. There would be lost some matter that had escaped during the process of evaporation.

Q. Can the matter be collected and weighed?

A. No, that is not done.

Q. Can it be done?

A. Well a great many things are possible that are not done.

Q. Can a chemist do it, is what I want to know, doctor; or is that beyond the scope of chemistry?

A. Well, that is never done.

Q. Can it be done?

2766 A. Well, you can determine that in a different method, by a method—

Q. Can it be done, doctor?

A. By distillation processes.

Q. Is there any reason why you cannot answer that question?

A. Well, it is never done.

Q. Can it be done.

A. Well so I presume it cannot be done.

Q. Then it cannot be done,—that is, to ascertain what the weight of the substances that disappear from sewage by evaporation, is that true?

A. Well, the way you construe it, yes sir.

Q. Now doctor, if that cannot be done, is there any way of ascertaining the quantity of sewage in 100 gallons of water as to quantity?

A. Well, this is estimated by certain chemical methods, and the quantity is determined according to the analytical results obtained.

Q. Suppose that the fecal discharge of man consisting of urine and feces, should be weighed, and five pounds of urine and feces should be placed in 100 gallons of water, and five pounds placed in 50 gallons of water; is there any way in chemistry to ascertain the amount of the feces and urine that has been placed in those two solutions?

2767 A. Yes sir, by chemical analysis.

Q. Chemical analysis?

A. Yes sir.

Q. Then if that is true, can you not ascertain the amount in pounds, or rather the quantitative amount of sewage polluting substance that enters into water?

A. Well that is done based upon chemical investigations.

Q. The amount of sewage producing substances that contaminate water does not depend upon the quantity of water does it?

A. Well, the analytical results would not be accurate unless the quantity of water there would be taken into consideration.

Q. If the water is increased, it does not lessen the amount of sewage polluting substance that enters it, does it?

A. Well, the analytical results would differ accordingly, according to the quantity of water that that sewage was dissolved in.

Q. If you can ascertain that five pounds of fecal and urine discharge is placed in 50 gallons of water, would it change that five pounds by putting 50 gallons more of water into the fifty that it already contained?

A. The chemical results would vary considerably.

Q. But would the quantity in solution vary?

A. The quantity in solution would show different results.

2768 Q. Would it be more or less than five pounds if you added 50 gallons of water?

A. Well, if you dilute it somewhat, the chemical results would show of course a smaller percentage—

Q. But would the amount increase or decrease by adding water?

A. The chlorines would show reduction by dilution.

Q. Would the amount increase or decrease by adding water, doctor?

A. Well, the amount itself—

Q. Would there be any more than five pounds of it, if you added fifty gallons more of water?

A. If you added like amounts to like volumes of water, the amount added to the two volumes of water is alike, certainly.

Q. But if you add 50 gallons of water with five pounds of feces and urine in solution, would the fact that you added 50 gallons of water increase or decrease the five pounds of feces and urine in the water?

A. Well, you added five pounds to it; that is five pounds larger then. After you add it to the water there is something new created; you have then a sewage polluted water, because much of that sewage immediately dissolves into the water.

Q. But wouldn't you have your five pounds of feces and
2760 urine in that 100 gallons of water?

A. It would show that originally five pounds of that matter had been added to that water.

Q. Then if you add 50 gallons more of water to that quantity wouldn't you still have your five pounds of urine and fecal discharge?

A. Well, those five pounds are immediately partly dissolved in the water and you have entirely different conditions then.

Q. But the five pounds would be there, wouldn't it?

A. No, you couldn't say that, because there is no more five pounds of sewage there then; the five pounds of sewage are partly immediately distributed or dissolved in the water.

Q. What has become of it?

A. It is dissolved.

Q. Well, it is there, isn't it?

A. It is dissolved, though; it is not there any more.

Q. You believe in the doctrine of the indestructibility of matter, do you not?

A. Yes, sir; it is one of the laws of nature.

Q. Well, that is there, isn't it—the five pounds?

A. Yes, sir; in that way.

Q. Now, could you, as a chemist, ascertain whether it was five pounds or twenty pounds in that water?

A. You mean after the chemical analysis?

2770 Q. No, after it has been mixed—five pounds of urine and
feeal discharge mixed with 50 gallons of water?

A. And I wouldn't know how much you had added, and you would want me to determine—

Q. No, we have first got 50 gallons of water. We put five pounds of fecal and urine discharge in that water—

A. Yes, sir.

Q. Now, could you by any process known to chemistry, analyze that water and state that five pounds of fecal and urine discharge has been put in there?

A. No, sir; I could not; I could only determine that sewage had been added to that, and the chemical analysis would show a percentage of sewage ingredients somewhat corresponding to the original quantity of sewage added to that water and dissolved in it partly, and partly not.

Q. Now, if we add 50 gallons more of water—pure water—to that water with the five pounds in it, would that make more or less than five pounds of polluting fecal and urine discharge in the water?

A. Well, it would show in the chemical results afterwards which are estimated. Estimated according to the quantity of water for certain chemical ingredients, it will show a reduction, for instance, of the chlorines. For instance, you have 2771 added so much water to that, it would reduce the chlorines.

Q. Doctor, do you understand my question?

A. I think I do.

Q. You really think you do?

A. Yes, sir.

Q. And you are not trying to evade it in any way, are you?

A. No, sir; I consider this a very serious matter, Mr. Todd. I am in duty bound to give an honest opinion, and I would attribute—

Q. Well, then, if you understand my question, doctor, will you tell me whether the addition of water increases or decreases the quantity of the polluting substances in that water?

A. It doesn't increase or decrease the quantity introduced into that water.

Q. That is my question, doctor?

A. Well, that it don't do.

Q. That is all I want to know.

A. But in chemical analysis, of course —

Q. I am not asking about chemical analysis.

A. The quantity of water added to the sewage is of some importance in determining the resuts.

Q. That is all I am asking you about, is that proposition

2772 Q. Now, having ascertained that fact, that the addition of water does not increase or decrease the quantity of this polluting substance in water; that is correct, isn't it?

A. Oh, no; you said upon sewage, or sewage as such—

Q. The quantity of the polluting substance of sewage?

A. Well, the polluting substances are the chemical ingredients that are in that sewage, according to chemistry.

Q. The polluting chemical ingredients of sewage in the form of substances?

A. Well, those will show in the analytical results according to the quantity of water—

Q. Wait, doctor, until I get my question. There is in sewage what is known as a polluting substance, is there not?

A. Yes, sir.

Q. The water that is in sewage in itself is not polluted, is it?

A. How is that question?

Q. The water that enters into sewage is not in itself polluted, is it?

A. Well, it may be pure water and it may be polluted water.

Q. Well, pure water added to sewage is not polluting, is it?

A. No, sir.

Q. Now, if 100 gallons of pure water is added to a gallon of sewage, there still is a gallon of sewage in that 100 gallons of water, is there not? 2773

A. Well, the moment that you put it into the water, the physical and chemical action takes place immediately and brings about a condition that that—

Q. There is so much more sewage then, is it not?

A. Well, it is diluted sewage, then.

Q. Diluted sewage?

A. Yes, sir.

Q. Well, I am speaking of sewage. You speak of diluted sewage as a tangible way of expressing it, is that true?

A. Well, that depends upon where this sewage is taken.

Q. Then, if at the controlling works at Lockport 300,000 feet of sewage diluted water was allowed to go over the Bear

Trap Dam, there would be 300,000 cubic feet of sewage enter into the Desplaines river, wouldn't there?

A. No, that would be 300,000 cubic feet of sewage diluted water, because that is a mixture of the sewage and water.

Q. Now, what is there in that water as it passes the Bear Trap Dam that is known as sewage?

A. The chemical analyses reveal that certain characteristic ingredients of sewage are to be found in that water, which justify the conclusion that sewage has been mixed with the water.

Q. Now, whatever sewage is defined to mean, is something tangible, isn't it? 2774

A. Do you mean tangible in its application?

Q. It is an entity, it is something tangible; it is a material?

A. Yes, sir.

Q. Now, call it what you want to and give to it any name that you please, will you tell me whether you know whether the sewage that entered the Desplaines river from Chicago prior to the opening of the Illinois and Michigan Canal was greater or less than the sewage from all of the tributaries of the Illinois river and the cities that were built upon its banks from Lockport to Grafton?

A. At times of low water stage—

Q. Doctor, I asked you if you knew? We have gone over the water business and that would only go over it again.

A. I am ready to answer that question.

Q. (Question repeated.)

A. At times of low stage of the Illinois river it was.

Q. Do you know?

A. Yes, at times of low river stages it was.

Q. It was what, greater or less?

A. Greater.

Q. The Chicago sewage was greater than all the rest or all the rest was greater than the Chicago sewage?

2775 A. The sewage discharged from the Illinois and Michigan Canal in its effects, as shown by the chemical analyses and applied to low water stages was greater at such times than the sewage from the tributaries and the towns.

Q. How much greater, doctor?

A. Well, I couldn't give the exact figures, because I would have to consult the original data, and compute the figures from those original data. I gave an approximation which leads me to that conclusion.

Q. Have you ever made a calculation?

A. I have made such calculations, yes, sir.

Q. When did you make them?

A. I made those calculations several years ago in preparing my report on the investigations in questions here.

Q. How much sewage did you give to the city of Peoria when you made that calculation?

A. I cannot recollect at this moment; I haven't got all those data fresh in my memory; it is several years ago since I computed them.

Q. How much sewage did you give to Chicago?

A. The sewage from the city of Chicago at that time I figured hypothetically from publications by authorities who had expressed opinions on the quantity of sewage from Chicago.

2776 Q. What do you mean by hypothetically?

A. Well, because it has never been estimated by engineers with the proper engineering methods applied, how much Chicago sewage is discharged through the Illinois and Michigan canal; that is scientific engineering calculations have not to my knowledge been made, or to my knowledge examined. I failed to find any such, although I looked for them very hard.

Q. Was any sewage emptied into the Illinois and Michigan canal except through the pumps at Bridgeport that you know of?

MR. JEFFRIES: If you know?

A. That I couldn't tell at this moment. I am not sure whether any adjacent towns on that canal did.

MR. TODD: I am talking about Chicago.

A. You are speaking of the Illinois and Michigan Canal now.

Q. I asked you if any sewage from Chicago entered the Illinois and Michigan Canal except at the pumping works at Bridgeport?

A. To my knowledge at this moment, only at Bridgeport.

Q. And hasn't data been kept of the number of gallons, the number of cubic feet that has been pumped every twenty-four hours for the last twenty years at the Bridgeport pumping works?

A. Yes, but that is not what I consider sufficient engineering data as to how much sewage of the city of Chicago 2777 enters the Illinois and Michigan Canal, because this sewage, the sewage of the city of Chicago, is discharged into a waterway, into the Chicago river and the speed of that river varies. The varying stages of the river cause varying conditions, sometimes the river stagnates and keeps that sewage in there for a long time before it reaches the pumps at Bridgeport, and then again, during storm water times, the flood water sweeps that sewage much faster and quicker, from the south fork principally, into the Illinois and Michigan canal; so that there are different conditions. Therefore it is not possible to say how much direct sewage goes into that canal. I will admit, or rather it is a matter of course that there are daily estimations made of the quantity of sewage pumped from the south fork of the south branch of the Chicago river into the Illinois and Michigan Canal.

Q. Is it not a fact that the sewage from the Chicago river enters the Illinois and Michigan Canal—that not a drop of the sewage from the Chicago River enters the Illinois and Michigan Canal except what is pumped in there?

A. Yes, sir; and that is my impression.

Q. And that sewage that is pumped in there comes from freshets in a more polluted condition or, if stagnation has been allowed to take place in the Chicago river, in a less polluted condition, but the amount of sewage always equals the 2778 amount that is pumped in from the Bridgeport Pumping Works?

A. The amount of sewage polluted water from the Chicago river, yes.

Q. From the Chicago River?

A. From the south branch of the Chicago river, to be correct.

Q. Now, from that amount in cubic feet, did you say that exceeds the sewage polluted water that comes from Springfield, Illinois, from Ottawa, from Peoria, from Pekin, from Beardstown, Virginia City and all the cities lying on the tributaries of the Illinois river, which empty into the Illinois?

A. At times of very low river stages, yes.

Q. And can you state how much in excess of the sewage of these different places that sewage amounts to?

A. I couldn't say at this moment, because I would have to compute accurate data there which will take me some time to calculate. I would have to get all the original figures.

Q. Have you ever made any personal investigation as to the amount of sewage from Springfield, Illinois that enters the tributary that leads into the Illinois river. Have you ever made an estimate?

A. The analyses from the Sangamon river suffices to demonstrate —

2779 Q. You can go on and I will move to strike out your answer as not responsive to the question.

A. Repeat the question?

Q. (Question repeated.)

A. I made an estimate as to the effect of that sewage on the Sangamon river.

Q. Have you made any estimate as to the cause of that effect?

A. It wasn't necessary.

Q. Have you made any estimate as to the cause of that effect, is my question?

A. No, it wasn't necessary.

Q. Whether it was necessary or not, is another matter. Have you made any estimate as to the amount of sewage draining into the Illinois river from Joliet, Illinois?

A. Yes, sir.

Q. How did you make that estimate, doctor?

A. I based that estimate on the water supply of the city of Joliet.

Q. Did you make any estimate at Pekin?

A. Yes, sir.

Q. How did you make that estimate?

A. I made that estimate from chemical analyses of samples of the water taken above and below Pekin.

2780 Q. When?

A. I made that several years ago during other investigations.

Q. Since or before the opening of the drainage canal?

A. I made that before and after the opening of the drainage canal.

Q. And did you arrive at the quantity of sewage that entered from that place?

A. I made some allowance there for the conditions prevailing in every small town like Pekin, that much of the sewage does not, or is not discharged into the river by the sewerage system, but goes into the surface soil through cess-pools and outhouses.

Q. What percentage did you base that on?

A. I don't remember now; it is some time ago since I computed those figures and I haven't got that in my memory just now.

Q. How do you figure out the quantity of sewage from Peoria?

A. The quantity of sewage from Peoria, I base that on the water supply.

Q. Did that water supply apply to the distilleries?

A. Well, that was to include all the sewage from the city of Peoria.

Q. Do you know how many tons of sewage or refuse is drained into the Illinois river every day by the distilleries
2781 of Peoria?

A. Well, directly, I don't know.

Q. Have you any idea?

A. Well the chemical analyses of samples taken above Peoria and between Peoria and Pekin, at such places where the distilleries run their swill into the Illinois river, because many of them run it directly into the Illinois river, and the chemical analyses made from the points where that swill is discharged directly into the river, enabled indirectly an estimation of the effect of the pollution of the Illinois River from the distillery swill.

MR. TODD: I move to strike out the answer and ask that the question be re-read.

Q. (Question repeated).

A. I cannot give an accurate figure directly, as to the quantity in tons.

Q. Prior to the opening of the drainage canal the Illinois river was a polluted stream, wasn't it?

A. Yes sir.

Q. When this report was made in 1893, that you have stated, and your report was made to the Board of Health, it was after that report was made that the Intake was placed at the Chain of Rocks, in the Mississippi River, wasn't it?

2782 A. Yes, in 1895 the intake was placed— No, the waterworks were removed, but whether or not the intake was in the course of construction in 1894—this report was made in December, 1893,—that I don't know, but my impression is that it was contemplated, if not in the course of construction.

Q. When the Intake of the St. Louis water supply was located at Bissell's point, there was an epidemic of typhoid in the city of St. Louis, wasn't there, caused by some creek right above Bissel's Point?

A. Yes sir, right above Bissell's point.

Q. That epidemic was attributed to that contaminated creek, wasn't it?

A. Yes sir.

Q. Then when the waterworks were changed out to the Chain of Rocks, did they have another epidemic?

A. To my knowledge there was no epidemic of that force after that.

Q. No, but they had a good sized epidemic for a few months there didn't they, in 1899?

A. In 1899, in November, there was somewhat of an epidemic.

Q. How many cases of typhoid were there in the month of November, 1899?

A. I will tell you that in a moment; I have the official figures here. There were 482 cases reported in November, 1899, of typhoid. 2783

Q. Do you know whether in any one month in any year previous to that one, that number of typhoid fever cases were reported?

A. Do you mean since the removal of the Intake?

Q. Before, at the time of the epidemic previous to that.

A. You mean in 1892.

Q. Yes.

A. You understand that the number of cases reported in 1892—

Q. Was 1180?

A. During that month was higher—

Q. During the year.

A. Now you are comparing November, 1899, with no previous month in the year.

Q. Yes. 480 cases.

A. 482 cases were reported in November, 1899.

Q. Now in the records of the Board of Health Department of the City of St. Louis, is there any month previous to that when as large a number of cases has been reported in one month?

A. Yes, in the year 1892, during that epidemic, ascribed to the Harlem Creek pollution, above the old intake—

Q. What month was that in?

A. Well, I haven't got the data for that at hand now, but it is my impression that it was a fall month; whether it was October or November.

2784 Q. How many cases were reported in either of those two months?

A. They were considerably higher than those in November, 1899; I don't know the exact figures; I haven't got those.

MR. JEFFRIES: Doctor, haven't you got the tables back for 1895?

A. No, I have only got the statistics for the period following the removal of the intake to the Chain of Rocks, above Harlem Creek.

MR. TODD: Haven't you the tables showing the month in which these 1180 cases of typhoid were?

A. Dr. Ravold presented that table, I believe, as an exhibit, but I haven't got it.

Q. Well, 482 cases in one month, makes quite a respectable showing for typhoid, doesn't it doctor?

A. Yes sir.

Q. What was the cause of that typhoid?

A. Well, the true cause for that typhoid has never been ascertained except that it has been ascribed to the polluted water supply.

Q. No reason then has been able to be found for explaining the presence of typhoid at that time in St. Louis?

A. Not to my knowledge.

Q. And that was before the opening of the drainage canal?

2785 A. Yes sir.

Q. Since the opening of the drainage canal have you had as many as 482 cases of typhoid in St. Louis in any one month?

A. No sir.

Q. Then the conditions in the public health of the city of St. Louis since the opening of the drainage canal has never reached the point in typhoid that occurred for any one month, in 1899, is that correct?

A. Based upon—

Q. Can you answer that Yes or No, if it is true?

A. If based upon the estimate of one month, you are right.

Q. Now doctor, there is just a little matter that I want to pay you a compliment on at the conclusion of my cross-examination, by having you tell me all that you know about the Kaw River and the sources from whence you get your information as to it running through a salt country?

A. Yes sir.

Q. From what data do you get the information that the Kaw River goes through a salt country?

2786 A. (Reading) "Mineral resources of the United States. Calendar year 1887. United States Geological Survey." A tabular presentation of Salt Deposits in the United States, published in this government publication under the title: "Useful Minerals of the United States, a partial list of ores, minerals and mineral substances of industrial importance arranged alphabetically by states and territories, edited by Albert Williams, Jr." This gives the useful mineral deposits for every state where such are found, and names the minerals as well as the quantities where the deposits have been found. It will be seen here on page 732 in the column, "Mineralogical Name," "Halite, common salt, brines and rock salt." It states there "Extensive deposits in Central part of State; Ossowatomie, Miomee county, several wells; near Hamlin, Brown County, springs; Valley of Fall River, Greenwood county; Mound City, Linn County, brine in wells; Marmiton, brine in wells; Emporia, Lynn County, Valleys of Fall and of Verdigris rivers, salt springs; State Salt Springs and other salt marshes in the belt of country crossing Republican, Solomon and Saline valleys, 80 by 35 miles; rock salt south of Great Bend of Arkansaw River, in beds six to twenty-eight inches deep Salt industries at Solomon City, Saline County; Junction City, Davis County; rock salt at Anthony (75 feet thick) Harper County; many borings at Hutchinson 250 feet thick, and Ellsworth, 140 feet thick; Lyons 250 feet thick, Kingman 200 feet thick; of considerable economic importance and remarkably pure." 2787

Now several tributaries of the Kaw River as well as the Kaw River itself, the Kaw River being 300 miles long, drain through several of these counties which are mentioned here as having salt deposits.

Q. Any other source of information on that subject, doctor, except what you have just read?

A. Well, I have discussed this problem with—

Q. I mean from literature first?

A. No, not from literature, no sir.

Q. Doctor, turn to page 622 of that same report.

A. Yes sir.

Q. Is anything said there about salt deposits?

A. Yes, it states there under the heading of "Kansas" what new discoveries of salt deposits have been made during the year 1887 for Kansas.

Q. Will you read that into the record please, doctor. You took that into consideration in regard to the Kaw River, didn't you?

A. No. While it was interesting to see that additional salt deposits had been discovered in Kansas, during 1887, the tabular statement of the mineral resources of useful minerals contained information of all sources of salt deposits in Kansas. 2788

Q. Then if you didn't take that into consideration, why I don't want it. If you didn't regard that at all as shedding any light upon the Kaw River.

A. Well, it did not, because it mentions the discovery of deposits there in counties that were not drained by tributaries of the Kaw or of the Kaw itself.

Q. Doctor, will you state briefly, what the chemical constituents of potable waters as found in rivers, are?

A. Do you mean the natural solids that are in the water, or do you mean impurities that would be permissible and the degree of impurities?

Q. Yes, that's it.

A. You mean the permissible impurities?

Q. Yes?

A. The definition of what is potable water should include a certain arrangement of the degree of impurities taken singly as compared with the general character of a water and the source of a pollution, or the character of the pollution, if the pollution of water should be permissible, and the water be allowed to be considered potable. Now do you want that chemically and bacteriologically, or do you only want it chemically?

2789 Q. I would have to cross-examine you for a couple of days if you go into bacteriology. I want to get through. As to bacteriology I have disregarded you. I am treating you now as a chemist, doctor, and chemically is what I want.

A. You see, the entire potability of water would depend upon both the chemical and bacteriological character of the water, but chemically I would consider water potable if it would be free from nitrites; would be free from free ammonia and albuminoid ammonia, and accordingly it would be free from albuminoid ammonia; it would not show organic matter in the analyses. However, since nature does not furnish such an ideally potable water to a multitude of communities, a liberal allowance must be made by communities for the presence of impurities such as nitrites, free ammonia, albuminoid ammonia and organic matter, as evidenced by the free and albuminoid ammonias. A trace of nitrites and low free ammonia and low albuminoid ammonia, with a comparatively low chlorine, or if the chlorine could be traced to sources not of a polluted character, such a water would be permissible.

Q. Have you completed the answer, doctor?

A. Yes sir.

Q. What proportion of albuminoid ammonia is permissible in potable water?

2790 A. Well, that would depend upon the corresponding amounts of chlorine and nitrites found in the water.

Q. What proportion of albuminoid ammonia, nitrite, chlorines and free ammonia is permissible in what is known as potable water of rivers.

A. Now there again a liberal allowance would have to be made for the conditions forcing a community to accept a water that would not be unpotable if it would have certain relative proportions of these ingredients, proving that whatever pollution formerly existed in that water, if any, that this pollution had been sufficiently removed so as to give that water a character of stability in its chemical ingredients as found present to a limited degree.

Q. Then if you could make a community take the water whether it contained these substances in a high or low degree, that would decide its potability?

A. Well, not entirely because the question would also have to be considered of the bacteriological character of the water before its degree of potability could be determined.

Q. Just eliminate the bacteriology part and stick to chemistry?

A. Yes, from a chemical standpoint alone.

Q. From a chemical standpoint alone, what?

A. I think that a liberal allowance could be made there if 2791 a general conclusion was justifiable, that the potability as accepted by the chemical character of that water would not affect public health injuriously.

Q. And that is the most concise answer you can give as to what is potable water in rivers?

A. Well, analytical limits as to the amount of impurities to be permitted in such water are frequently formulated, but while such limits could be applicable to conditions prevailing in the only possible water supply of a community at one place, they may be different at another place, so that such a limit might be severe in such an instance, and if the general effect on the public health of that community would not be injured by that construction of that so-called standard, such a standard of potability could be adopted in that particular case.

Q. Then the standard of potable water—then the moral to be drawn from what potable water is "Give the people what they think they want" is the test isn't it?

A. If it is not injurious to the public health.

Q. And as far as the chemist is concerned, he cuts very little figure in the determination of what is potable water unless the people accept his views on the subject, is that right, doctor?

A. No. I would say it would depend upon the effect
2792 upon the general public health that the practical application of that standard would have.

Q. So, after all, the people are the judges as to what is potable water or not, and it depends upon the caprices of the people to a large extent?

A. It depends upon public health statistics.

Q. And if the people can stand the water, why it is potable?

A. If the public health statistics show that the water doesn't have any injurious effect on the public health, such water can be considered permissible.

Q. Doctor, have you ever formed an opinion as to whether the waters at New Orleans after receiving the sewage discharge of the entire Mississippi Valley, is sewage polluted or not, or potable?

A. I have not given the analytical data obtained by other investigators on the chemical character of the Mississippi River water at that point any study.

MR. WOERNER: Why don't you say Yes, doctor, and be done with it?

A. I won't say that, I haven't studied the data, but I am not able to answer that question now, positively or negatively.

Q. That's what he asked you, whether you knew.

A. I don't know.

WILLIAM C. TEICHMANN.

ADJOURNED until 10:00 A. M. Saturday, April 4, 1903.

2793 Southern Hotel, St. Louis, Missouri. 10:00 A. M., Saturday, April 4, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

DR. WILLIAM C. TEICHMANN,

Resumed the stand for re-direct-examination by Mr. Jeffries, and testified as follows:—

Q. Doctor state whether or not the fact can be ascertained that the Kaw River runs through saline regions or salt laden soil, from the analyses of the water, by judging from the high number of chlorines found in the water?

A. Yes sir.

MR. TODD: I object to the question on the ground that it is not re-direct of anything that has taken place, and has been covered in chief.

Q. Now what information have you aside from literature and geological reports, that leads you to believe that the Kaw River runs through salt laden territory?

MR. TODD: I object to that for the same reason as is expressed in the former objection.

Q. Go ahead.

2794 A. The results of chemical analyses made of samples of water collected from the Kaw river.

Q. What were those results?

MR. TODD: I object to that question on the ground that in his direct-examination he has already given the results.

MR. JEFFRIES: If that is true, I will withdraw the question, because I was not here when he was examined.

Q. You answered that, did you doctor?

A. Yes sir, the analytical results have been read.

MR. JEFFRIES: I withdraw the question.

Q. Doctor, assuming that the waters of the Illinois River have been condemned as unpotable; assuming that the important tributaries of the river have likewise been condemned as unpotable, and assuming the fact that the effect of the waters of the Illinois river on the Mississippi at their junction or at any point below their junction did not render the Mississippi river water unpotable prior to the opening of the canal; what effect has the opening of the canal, carrying the Chicago sewage into the Illinois river had from your chemical analyses upon the Mississippi River water?

MR. TODD: I object to that question on the ground that it assumes that the waters were condemned without stating by whom or what method the condemnation has been made, and for the further reason that it is not re-direct examination.

2795 ATTORNEY GENERAL HAMLIN: And for the further reason that this witness has testified to the facts in the case and he is now asked an opinion not based upon the facts that he has testified to.

MR. JEFFRIES: Go ahead and answer, doctor?

A. Do you refer to the drainage canal?

Q. I refer to the Mississippi River water and the effect that the drainage canal has had upon it since the opening?

A. Now would you read that question please, over again.

Q. (Question read)?

A. A polluting effect.

Q. State whether it rendered it unpotable or not?

A. It rendered it unpotable.

RE-CROSS-EXAMINATION.

By Mr. Todd.

Q. Doctor, if water is unpotable, will the addition of additional sewage render it more unpotable?

A. Yes sir.

Q. Then if the waters of the Illinois and its tributaries had been condemned as being unpotable before the entrance of the drainage canal into the Illinois river, after that event took place, the water would be more unpotable, would it?

A. Well the increased pollution would of course have an 2796 increased effect on the public health of such community that would use that water for a water supply, and in that respect I would say that it is more unpotable.

Q. That is, if it is unpotable before the addition, it would be more unpotable to a degree?

A. Yes, as judged by its effect on the public health of the community that would use that water as a water supply.

Q. And if the people thought that they wanted to use that water and did use it, it would be potable for all practical purposes, would it not?

A. You mean after the increased pollution. Yes sir.

RE-DIRECT-EXAMINATION,

By Mr. Woerner.

Q. Doctor, do you mean to say that it is your idea that the potability of water depends upon the opinion of the people that are drinking it?

A. No sir.

Q. Now then, I wish you would explain what you meant by the answer to the last question that was asked you by Mr. Todd?

A. Well, will you read that question—not the last one, but the one preceding the last one?

Q. (Question read as follows:) "And if the people thought that they wanted to use that water and did use it, it would be potable for all practical purposes, would it 2797 not?"

A. The potability of the water could only be judged by its effect on the public health.

Q. How do you determine whether it is potable or not?

A. I determine it by the chemical analyses and a general consideration of the analysis from a chemical and bacteriological standpoint.

Q. Well now, isn't that the only way to ascertain whether it is potable or not?

A. Well that is a theoretical way. The practical way would be to judge its effect upon the public health.

Q. But the idea of the people that are drinking it ha nothing to do with that?

MR. TODD: I object to the question as leading.

A. No sir.

BY MR. TODD:

Q. Has the people's judgment anything to do with the potability of water?

A. Well the experience of the people in drinking the water may enable them to form an opinion.

Q. People who are used to drinking a certain water become accustomed to its use, do they not?

A. Somewhat, yes sir.

2798 Q. And people who are not accustomed to drinking that character of water, when they drink it, it affects them injuriously, does it not?

A. The experiences of some communities show that the strangers are more susceptible to the water than the inhabitants of the city that drink that water.

Q. Well water that would be potable in St. Louis would not be potable to the people of some other city, would it, until they got used to it?

A. Well to some degree, the people from the other cities if they would visit the city where that water is not good, they would be more susceptible to it.

Q. And its use and becoming adapted to the use of water—that decides in a large measure its potability, does it not?

A. In a measure; it might be taken into consideration.

Q. And in the case of St. Louis the people become immune to the water that they drink?

A. To a certain extent they become accustomed to the water and their susceptibility as to diseases from polluted water may be lessened, but the susceptibility is not removed.

Q. Can a chemist, without knowledge of local conditions from analyses, pass upon the potability of water in streams?

A. No sir.

WILLIAM C. TEICHMANN.

2799 PROF. EDWARD H. KEISER,

Resumed the stand for further direct-examination by Mr. Jeffries, and testified as follows:—

Q. Professor Keiser, I will ask you if you have made an examination from data furnished you by the Board of Health of the City of St. Louis, of the condition of the water supply of St. Louis, and subsequent and prior to and after the opening of the Chicago Drainage canal?

A. Yes sir.

Q. Will you state briefly the result of your examination?

MR. JOHNS: I object to the result of the examination as incompetent and not being founded on sufficiently recognized data.

Q. MR. JEFFRIES: State where you got the data?

A. I obtained the data from the Water Commissioner of St. Louis, Mr. Edward Flad, and from the office of the City Chemist, Dr. Teichmann. I received it from Dr. Teichman, also some data from my own laboratory, the Washington University chemical laboratory.

Q. Now you may state the result of your examination?

MR. JOHNS: I still object on the same grounds as before stated and on the further ground that such comparisons are not competent evidence, as the data if in existence, are the 2800 only evidence, and the comparison is a matter of law, and not of fact. It is a matter for the Court.

Q. MR. JEFFRIES: Have you got the data?

A. Yes, I have some of them here and the other data are in the room below.

MR. JEFFRIES: If you insist on all of the data Mr. Johns, we can burden this record with it. It will take time to get it all in.

MR. JOHNS: You can take your own course. I simply object at this time.

THE WITNESS: They are all in the building; the tables are all here.

Q. MR. JEFFRIES: Well, go ahead; state the result of your examination and we will get the data afterwards.

A. In the first place, I have tabulated all the analyses that were made of the waters of St. Louis prior to the opening of the Chicago Drainage Canal, and I find that the records go back to the year 1894. In the first place there are reported seventeen analyses of water from the distributing well. These analyses were made from May 2, 1893 to January 24th, 1894. They are reported in the Mayor's message,—the Mayor of St. Louis, annual message for 1894, page 418, and here are these analyses taken out of the Mayor's message for 1894 (Exhibiting sheets of paper). The average results as here printed for the 2801 condition of the water supplied to St. Louis are as follows:

Free ammonia—this is the average of the seventeen analyses—Free ammonia .046.

Nitrites—that means parts per million of nitrogen—Nitrites .003 parts per million.

Albuminoid ammonia 1.033 and nitrates .38 parts per million.

Then we have in the same report seventeen analyses of water from the settling basins made from April 14th, 1893 to January 24th, 1894, and they gave the following average results:

Free ammonia,	.019,
Nitrites,	.002,
Albuminoid ammonia,	.411,
Nitrates,	.44.

Then a series of twenty-one analyses were made at intervals from December 15, 1892 to April 20th, 1894 in the chemical laboratory of Washington University. They gave the following average results. These are the originals, the twenty-one analyses. Now the average at the bottom is as follows:

Free ammonia,	.048,
Nitrites,	.005,
Albuminoid ammonia,	.310,
Nitrates,	.38.

2802

In addition to these results twenty-six analyses were made by the city chemist of the intake water at intervals from September 9th, 1899, to January 22nd, 1900. The average values—

MR. JOHNS: Wait a minute. I object to the statement as to the results of these analyses because, it has already been introduced in evidence in this case.

A. (Continuing) The average values for these analyses are as follows:

Free ammonia,	.063,
Nitrites,	.002,
Albuminoid ammonia,	.552,
Nitrates,	.39.

Comparing these averages obtained in different years we see that there was but very slight change in the character of the water supplied to St. Louis. The free ammonia ranged between—

Q. MR. WOERNER: What year are you talking about?

A. Supplied to St. Louis previous to the opening of the drainage canal.

The free ammonia ranged between .019 and .063 parts per million. The nitrites varied from .002 to .005; the albuminoid ammonia from .310 to 1.033, and the nitrates were practically constant. 2803 The maximum value for free ammonia before the water of the Drainage Canal reached St. Louis was .138 on January 21st, 1900, and for nitrites the maximum value was .01 on the same day.

These analyses that are recorded prior to the opening of the canal show that the water was comparatively stable, and that it was not an unwholesome water compared with its present condition.

Q. Now give the condition of the water after the opening of the canal?

A. On January 17th, 1900, the Drainage Canal was opened. The water must have reached St. Louis about the beginning of February, 1900, and the effect of that opening on the St. Louis water is clearly seen in the results of the analyses made daily during the month of February—twenty-eight daily analyses of intake water made by the City Chemist gave the following average values?

MR. JOHNS: I object now to the recitation here of the results and conclusions from analyses made after the opening of the Drainage Canal, first because they have twice been introduced in evidence here and are already in the record, and second because the conclusions are not competent evidence in this case.

Q. MR. JEFFRIES: Go ahead doctor?

A.

Free ammonia,	.217,
Nitrites,	.013,
Albuminoid ammonia,	.676,
Nitrates,	.6.

2804

The impurities tend to increase during March as is shown by the following value for thirty-one daily analyses in March, 1900:

Free ammonia,	.348,
Nitrites,	.014,

Albuminoid ammonia, 1.202,
Nitrates, .8.

The average results for April, 1900, were free ammonia .186,
nitrites, .020
albuminoid ammonia, 1.036,
nitrates, .6.

A portion of this great increase in free ammonia and nitrites noticed in February and March, 1900, may have been due to the fact that in the winter months, impurities usually are found to run higher than in spring and summer, but the increase in the months of February and March, 1900 was very much greater than had been observed in any previous analyses, and further the water from this time on was found to have been permanently changed. Subsequent analyses show that in 2805 the spring and summer months, following, the water did not return to its former condition, but had been permanently polluted; thus the monthly averages for April, May and June, and for each following month until June, 1901, are as follows: And I have here a table. Shall I read this off, this table?

MR. JEFFRIES: It is too long, isn't it? It can be copied into the record.

(Said table is in words and figures as follows:)

		Free Am.	Nitrites.	Alb. Am.	Nitrates.	Chlorine.
April,	1900,	.186	.020	1.036	.6	9.
May,	"	.094	.011	1.190	.5	10.
June,	"	.070	.004	1.148	.3	11.
July,	"	.127	.004	1.350	.3	10.
August,	"	.101	.005	.810	.4	12.
Sept.	"	.093	.004	.818	.7	15.
Oct.	"	.118	.006	.898	.6	9.
Nov.,	"	.098	.007	.705	.6	10.
Dec.,	"	.105	.011	.289	.4	17.
Jan.,	1901,	.144	.009	.396	.8	19.
Feby.,	"	.121	.007	.296	.7	19.
March,	"	.310	.013	1.455	1.3	11.
April,	"	.191	.016	1.034	1.1	6.
May,	"	.088	.002	.506	.4	9.
June,	"	.105	.002	1.161	.5	10.

2807 A. (Continuing) The average results for this table, are as follows:

Free ammonia,	.150,
Nitrites,	.009,
Albuminoid ammonia,	.880,
Nitrates,	.6.

Comparing this now with the average result before the opening of the canal, namely, free ammonia, .063,

Nitrites,	.002,
Albuminoid ammonia,	.552, and
Nitrates,	.39,

we see that there has been a very decided increase in each of these forms of nitrogen and that the chemical analyses show a permanent pollution of the water.

According to generally accepted standards of potability, a water having .150 parts of nitrogen as free ammonia, and .009 parts of nitrogen as nitrites, would be condemned as unsanitary.

Q. Now give us the sanitary condition of the Missouri River water before and after the opening of the Drainage Canal?

MR. JOHNS: I move to exclude the entire answer of the witness to the last interrogatory, as argumentative.

2808 A. In looking over the statistics of the Health Department of the City of St. Louis, I found eleven analyses of water of the Missouri River taken at a point above the mouth of the stream, are on record in the Health Department of the city of St. Louis.

MR. JOHNS: I object to the announcing of the results of those analyses, and the average of them, on the ground that it is all of record as testified by the witness.

A. The average results of these analyses were:

Free ammonia,	.080,
Nitrites,	.001,
Albuminoid ammonia,	.657,
Nitrates,	.4.

And the average values of eight analyses made in the chemical laboratory of Washington University of Missouri River water taken at Fort Bellefontaine, Missouri, from January 23rd to January 31st, 1900, are as follows:

Free ammonia,	.134,
Nitrites,	.008,
Albuminoid ammonia,	.342,
Nitrates,	.39.

The average of all these recorded analyses of Missouri River water prior to February 1st, 1900, are as follows:

	Free ammonia,	.107,
2809	Nitrites,	.0045,
	Albuminoid ammonia,	.499,
	Nitrates,	.39.

After February 1st, 1900, daily analyses of Missouri River water were made by the City Chemist until October 10th, 1900, and also during the period October 1st, 1901 to November 30th, 1901.

MR. JOHNS: I object to the announcement of the average values of the results of the chemical analyses during the periods named by the witness because they have been twice testified to already and are of record and it is merely a matter of computation.

MR. JEFFRIES: Go ahead?

A.	Free ammonia,	.142,
	Nitrites,	.007,
	Albuminoid ammonia,	1.203,
	Nitrates,	.5.

And for the second period the averages are:

Free ammonia,	.069,
Nitrites,	.003,
Albuminoid ammonia,	.631,
Nitrates,	.55,

Now the averages of both of these series are as follows:

2810	Free ammonia,	.105,
	Nitrites,	.005,
	Albuminoid ammonia,	.917,
	Nitrates,	.5.

Comparing these averages now, with the averages of analyses before February 1st, 1900, namely:

Free ammonia,	.107,
Nitrites,	.0045
Albuminoid ammonia,	.499,
Nitrates	.39,

We see that there is but a slight difference in the average condition of the Missouri during these two periods. In other words, the Missouri River during the period of September 2nd, 1899, to November, 1901, has undergone no permanent change in its sanitary character. The same fact is shown by comparing the average results obtained by the City Chemist on September 2nd to December 4th, 1899, with the average results obtained by him in October and November, 1901. Those analyses in the form of an average give

Free ammonia,	.080,
Nitrites,	.001,
Albuminiod ammonia,	.657,
Nitrates,	.4.

In the later period, which was two years later, but at the 2811 same time of the year we find

Free ammonia,	.069,
Nitrites,	.003,
Albuminoid ammonia,	.631,
Nitrates,	.55,

We see from these that while St. Louis water had undergone a marked deterioration, the Missouri River water had remained unchanged. It is true that in the winter months the impurities in this river are higher than in the summer. This is true of all streams, but we see that in the fall of 1901 the water had again returned to its former condition. These results show then, that the increase of impurities in the St. Louis water, did not come from the Missouri River.

MR. JOHNS: I move to strike out the entire answer as an argument.

Q. MR. JEFFRIES: Those are conclusions arrived at based upon the data which you have given, are they not?

A. They are.

Q. Now give us the sanitary condition of the Mississippi River before and after the opening of the drainage canal?

A. There are recorded in the health department of the City of St. Louis, analyses made by the city chemist, seventeen analyses of the Mississippi River collected at Hartford, Illinois, a point about one mile above the mouth of the Missouri River. These samples were collected at intervals between Au-

2812 gust 3rd, 1899, and December 4th, 1899. The average results of these analyses are as follows:

MR. JOHNS: I object to any statement of the average results taken from these analyses, because the analyses are not proven and the persons who made the analyses are not produced as witnesses and are not subject to cross-examination.

A. The average results are as follows:

Free ammonia,	.107,
Nitrites,	.004,
Albuminoid ammonia,	.622,
Nitrates,	.5.

These were all made before the opening of the drainage canal. After the opening daily analyses were made from January 23rd, 1900 to October 10th, 1900, upon samples taken at Hartford. The average values for these analyses are as follows:

Free ammonia,	.275,
Nitrites,	.018,
Albuminoid ammonia,	.613,
Nitrates,	.7.

Daily analyses were also made from October 1st, to November 30th, 1901, and the averages obtained were:

Free ammonia,	.062,
Nitrites,	.011,
Albuminoid ammonia,	.368,
Nitrates,	.54.

2813 Averaging both series that were made subsequent to the opening of the drainage canal we get:

Free ammonia,	.236,
Nitrites,	.017,
Albuminoid ammonia,	.568,
Nitrates,	.67.

Comparing these results with the average condition of the Mississippi River at the same point before the opening of the Canal, namely:

Free ammonia,	.107,
Nitrites,	.004,
Albuminoid ammonia,	.622,
Nitrates,	.5,

we see that there has been a permanent increase of the pollution of the water. The water of the Mississippi like that of the St. Louis intake has been very materially inferior in sanitary quality since February, 1900, and further, these analyses show that since the St. Louis water is a mixture of the water of the Missouri and the Mississippi the increased impurities of the St. Louis water must have come from the Mississippi river and not from the Missouri river.

MR. JOHNS: I move to strike out the latter part of the answer as an argument.

2814 Q. MR. JEFFRIES: Now give the condition of the Mississippi River above the mouth of the Illinois River?

A. It having been shown by the previous analyses that the Mississippi River is a carrier of the impurities to the St. Louis intake, it is now of importance to determine how these impurities find their way into the Mississippi. The question arises: Do these impurities come down the main stream of the river or from the Illinois River. Eighteen samples of water were taken from the Mississippi River at a point above the mouth of the Illinois river. These samples were collected at intervals between September 6, 1899, and January 17th, 1900. The average values of the analyses made by the city chemist are as follows:

Free ammonia,	.069,
Nitrites,	.002,
Albuminoid ammonia,	.503,
Nitrates	.3,
Chlorines,	6.0.

Daily analyses of the water from this point were also made from January 23rd, 1900 to October 10th, 1900. The averages obtained are as follows:

Free ammonia,	.138,
Nitrites,	.008,
Albuminoid ammonia,	.587,
Nitrates,	.46,
2815 Chlorines,	5.0.

Daily analyses were again made from October 1st, to November 30th, 1901, and the averages obtained were:

Free ammonia,	.057,
Nitrites,	.001,

Albuminoid ammonia,	.348,
Nitrates,	.1,
Chlorines,	4.3.

Comparing these with the results as given, we see that the Mississippi River above the mouth of the Illinois, while higher in impurities in the winter months, returned in the fall of 1901 to a condition very similar to that which it was in 1899. The amounts of free ammonia and nitrites are relatively low in this stream and it is very similar in sanitary character to the Missouri River above its mouth. Plainly then, the upper Mississipi is not the source of the impurities that pollute St. Louis water.

Q. Now, professor, give the results of the analyses of the Illinois River made three miles above Grafton.

A. Nineteen samples of the water of the Illinois River from a point three miles above Grafton were collected and analyzed by the City Chemist at intervals between September 6th, 1899 and January 17th, 1900. That was before the opening of the canal. The average values found are as follows:

2816 Free ammonia,	.215,
Nitrites,	.012,
Albuminoid ammonia,	.553,
Nitrates,	.8,
Chlorine,	25.0.

These results show that at this time the water was badly polluted and not fit for drinking according to accepted standards. From January 23rd to October 10th, 1900, daily analyses were made of water from the same point, and again in October and November, 1901. The averages for the first series are as follows:

Free ammonia,	.272,
Nitrites,	.032,
Albuminoid ammonia,	.509,
Nitrates,	.96,
Chlorine,	13.0.

For the second series:

Free ammonia,	.110,
Nitrites,	.043,
Albuminoid ammonia,	.373,

Nitrates,	1.71,
Chlorine,	21.6.

The average values for both series of analyses are as follows:

2817	Free ammonia,	.239,
	Nitrites,	.034,
	Albuminoid ammonia,	.482,
	Nitrates,	1.11,
	Chlorine,	14.7.

We see from these that for the ten months since the opening of the drainage canal there was an increase in free ammonia of nearly 27 per cent and of nitrites 167 per cent. We can only conclude from these figures that after the canal was opened there was a much larger quantity of sewage undergoing putrefactive changes, than before in 1901, although the proportion of free ammonia had fallen somewhat, the nitrites had gone up to .043 parts per million, an increase of 258 per cent over what they were before the opening of the drainage canal. The Illinois River is thus shown to be the stream which, with its high free ammonia and nitrites, contaminates the Mississippi, and the Illinois River at its mouth is found to be in a much more polluted condition since January 23rd, 1900, than it was prior to that time. It is therefore the Illinois River that has caused the permanent increase in the impurities of the St. Louis water. The analyses have shown that both the Missouri River and the Mississippi River above the Illinois have undergone no permanent change but the Illinois River has been rendered more impure as a result of the opening of the
2818 drainage canal.

MR. JOHNS: I move to exclude the answer as an argument.

MR. JEFFRIES: Now can you give the condition of the Illinois river at the points above Peoria?

MR. JOHNS: I object to the question because the matters inquired of have already been placed in evidence twice and the conclusions drawn have also been placed in evidence twice.

A. There were no analyses of the water of the Illinois river at points above Grafton made by the city chemist before the opening of the canal, but from January 23rd, 1900, to October

10th the same year, daily samples were taken at a point three miles above Peoria, and occassional samples at Joliet and at Lockport. Samples were also taken from the Illinois and Michigan Canal and from Lake Michigan. These analyses show that as we ascend the river from Grafton to Chicago, the water becomes steadily more and more impure. This fact is clearly shown by the average values obtained from the Illinois: Thus, the average values from samples taken three miles above Grafton, are as follows:

Free ammonia,	.239,
Nitrites,	.034,
Albuminoid ammonia,	.482,
Nitrates	1.11,
Chlorine,	14.7.

2819 The average values for samples taken three miles above Peoria are as follows:

Free ammonia,	.468,
Nitrites	.095,
Albuminoid ammonia,	.284,
Nitrates,	1.48,
Chlorine,	19.4,

And the average values from samples taken at Joliet in 1901 are as follows:

Free ammonia,	2.732,
Nitrites,	.057,
Albuminoid ammonia,	.452,
Nitrates,	.22,
Chlorine,	23.9,

and the averages of samples taken from the Illinois and Michigan Canal, are as follows:

Free ammonia,	13.250,
Nitrites,	.009,
Nitrates,	None,
Chlorine,	150.0.

The averages from the drainage canal, Lockport, Bear Trap Dam are as follows:

Free ammonia,	1.585,
Nitrites,	.026,
2820 Nitrates,	.15,
Chlorine,	15.0.

Now for the sake of comparison, the averages of the water from Lake Michigan are as follows:

Free ammonia,	.043,
Nitrites,	.005,
Nitrates,	.15,
Chlorine,	6.0,

Q. MR. JEFFRIES: Now what conclusions do those results show or lead you to?

MR. JOHNS: I object to the answer and move to strike it out as an argument.

Q. (Question repeated)?

MR. JOHNS: I object to the question as the conclusions have already been testified to and are not at any rate, competent evidence.

A. We see that the entire Illinois river is in a highly polluted condition. The figures obtained at Joliet and those for the Illinois and Michigan and Drainage Canals are such as would have been obtained from sewage in its early stages of decomposition. Lake Michigan has .043 parts of free ammonia and .005 parts of nitrites. Now by the admixture with the sewage in the Chicago River, we find that when it reaches the drainage canal the free ammonia has increased to 1.585
2821 and nitrites to .026 parts per million. The Illinois and Michigan Canal is still more highly charged with sewage and gives 13.250 parts of free ammonia. These two canals carry sewage into the Illinois River by dilution with the water of the river, we find free ammonia .468 at a point three miles above Peoria. The nitrites, however at this point are higher, namely .095. Going down then to Grafton we find that the free ammonia has fallen to .239, and the nitrites to .034, but this is still far from being in a condition fit for drinking. We see that the oxidation and self-purification processes become very slow as the concentration of the sewage is diminished, and for the same reason we find these impurities in the water of the Mississippi and in the water of the St. Louis waterworks.

MR. JOHNS: I move to exclude the answer as an argument.

CROSS-EXAMINATION, BY MR. JOHNS.

Q. By whom were the seventeen analyses from the distributing well made in the period ranging from May 2nd, 1893, to January 4th, 1894?

A. They were made by the Water Department of the City of St. Louis, Mr. M. L. Holman, water commissioner.

Q. Where did you obtain these figures?

2822 A. I obtained these figures from the annual report of the Mayor of St. Louis for 1894, page 418.

Q. You know nothing whatever as to the time of the analyses of any of these samples prior to January, 1900, with reference to their being taken from the water?

A. Yes, the dates are all stated for those in that report from the Mayor's message of 1894, and also these others that are recorded below. The date when the samples were taken is always indicatd.

Q. When was the sample of May 2nd, 1893 taken, and how long after it was taken was it analyzed?

A. Well, it was taken May 2nd, 1893, and it was analyzed in a short time after that, in a very short time after that.

Q. Have you any knowledge of that fact?

A. None except what is stated in the report of the water commissioner.

Q. Do you know as to any one of the samples in the paper I have in my hand marked "Appendix I" Annual Report of the Water Commissioner for the year ending 1894, M. L. Holman, what time of the day, or any one of the days mentioned in the first paragraph of this table, that the sample was taken, from what point and what time elapsed from the taking of the sample until this analysis was completed?

A. They were taken at the St. Louis intake but I don't 2823 know what time elapsed after the taking until they were analyzed.

Q. Do you regard the St. Louis intake as the same thing as the distributing well?

A. No sir, but the water is very much the same.

Q. Well, the samples upon this paper to which I have referred, and which I have described in a previous question, and which you have inclosed in pencil marks, are from the distributing well and samples from the clear wells, are they not?

A. Yes sir.

Q. As to any of these samples in the paper described in group D and group C, can you tell at what time they were taken from either the distributing wells or from the clear wells and how long a time elapsed until they were analyzed after they were taken?

A. No sir.

Q. Do you know personally anything in refrence to the manner in which those samples were kept for the purposes or plan by which they were analyzed?

A. Yes sir.

Q. I mean, do you personally know anything about it?

A. No, except what I have read in that report. The method of the analyses is there described.

Q. Your knowledge then in reference to it, is derived 2824 from the report?

A. Yes sir.

Q. And your knowledge as to that is derived from the printed copy of the report?

A. Yes sir.

Q. Now when you were reading off these results, why did you not state the amount of oxygen consumed?

A. Simply to make the report concise and not to over burden the report with the table of figures.

Q. Do you know whether as to those samples of May 2nd, 1893 to January 24th, 1894, in group D, and from April 14th, 1893 to January 24th, 1894 in group C, there was determined the amount of solids in suspension?

A. There was a statement there of solid matter, of total solids.

Q. Why didn't you state that in giving these figures?

A. I don't know.

Q. Were you instructed not to?

A. Oh, I misunderstood you. What is the question?

Q. Why did you not state them in giving these figures?

A. The solids, simply because it would throw very little light upon the sanitary condition of the water.

Q. Was there any statement made of the solids in solution?

A. No sir, I made no statement of that.

2825 Q. Was there any statement in the report of solids in solution?

A. I don't remember, but we can see by looking at that.

Q. Whether there was or not, do you regard the question of solids in solution as having anything to do with the potability or unpotability of the water?

A. Very little. Very little information can be derived from that as to the sanitary character of the water.

Q. Were there any statements in the report of chlorines?

A. No sir.

Q. And therefore as to those results obtained from the examination of the report, you made no statement as to the chlorines?

A. No sir.

Q. Would you be able to give an opinion as to the sanitary condition of the water without a knowledge of the chlorine?

A. Yes sir.

Q. In your opinion chlorine does not enter into the proper consideration of the potability of water?

A. Not of the St. Louis water.

Q. I am asking about water in general.

A. Oh yes.

Q. In order to determine the potability of water there should be taken into consideration the chlorines, shouldn't 2826 there?

A. Yes sir.

Q. Also the oxygen consumed?

A. The oxygen consumed is not always taken into consideration.

Q. Shouldn't it be properly taken into consideration in the fair opinion as to the potability of water?

A. It assists in forming an opinion.

Q. Well then, it should be taken into consideration shouldn't it?

A. At times I think it is valuable to do it, and at other times it isn't of very great importance.

Q. Abstractly without refrence to the matter now under investigation, is it necessary to take into consideration that subject?

A. It is advisable at times to do it.

Q. At what times?

A. When you know very little about the natural history of the water. It is very desirable then to get all the data that one can in regard to the water before passing judgment on it.

Q. And do you make a distinction between oxygen consumed and oxygen consuming power of water?

A. Those terms mean the same.

2827 Q. Do you make any distinction between dissolved oxygen and oxygen consumed?

A. Yes sir.

Q. Is it necessary in a fair consideration of the potability of water eliminating now any consideration of this case, to know the amount of oxygen dissolved?

A. It isn't usually done.

Q. Is it necessary?

A. It is not very necessary.

Q. Is it necessary at all?

A. I don't think so.

Q. Was the oxygen dissolved stated in the report from which you took these or drew these conclusions?

A. I don't remember that it was.

Q. Can you form an opinion on the potability of a sample of water which has, only so far as your information is concerned, the following elements: Free ammonia .046; nitrites .003; albuminoid ammonia 1.033 and nitrates .38, and if so, what is that opinion?

A. Yes sir, I should say that water was not unsanitary.

Q. Is it potable water?

A. Yes, drinkable water.

Q. Is there a distinction between potable water and drinkable water?

2828 A. I think not; I think they mean the same.

Q. Do you know anything in regard to the samples taken from the clear wells from April 14th, 1893 to January 24th, 1894 as to the time when they were taken and the time elapsing before they were analyzed?

A. No sir.

Q. Do you know anything with reference to the series of nine samples from December 17th, 1892, to April 20th, 1894, in the chemical laboratory at Washington University as to the time when the samples were taken?

A. Yes.

Q. The place from which they were taken and the time elapsing from being taken until analyzed?

A. Yes sir.

Q. State what you know in reference to it personally?

A. I have here a table giving the individual analyses of the samples taken from December 15th, 1892 to April 20th, 1894, stating the exact date upon which these samples were taken and giving in addition to the averages here, giving the actual results obtained, not only for these statements but also for the solids, the total solids and chlorine, and stating whether they were filtered, or unfiltered, and this part of the report if you would like to see it.

MR. JOHNS: I move to strike out the answer as not responsive to the question.

2829 Q. Referring to the former question, have you any personal knowledge as to the taking of the samples in that question mentioned?

A. No, sir.

Q. Nor as to their analyses?

A. No, sir.

Q. Have you any personal knowledge as to the samples taken from September 9th, 1899, to January 22nd, 1900, in the office of the City Chemist, of the intake water?

A. I have no personal knowledge of those.

Q. From what source did you draw the conclusions that you have given as to that water?

A. I have taken the figures from the tables furnished by the city chemist and drawn up these averages.

Q. As to those 26 samples, how did you obtain the averages mentioned?

A. I obtained the average for free ammonia by adding together all the recorded values for free ammonia found in those 26 samples and then dividing the whole number by 26.

Q. And the same process as to the nitrites?

A. Yes, sir.

Q. And as to the albuminoid ammonia and nitrates?

A. Yes, sir.

Q. Taken in the abstract without reference to anything
2830 and—taken in the abstract without reference to anything
than the elements of pollution stated by you, to-wit, free ammonia .063, nitrites .002, albuminoid ammonia .552; nitrates .39. Are those figures sufficient to warrant you in a conclusion as to the potability of that water?

A. I think so.

Q. What is your conclusion as to that?

A. It is potable water.

Q. If I remember correctly, after January 17th, 1900, you were engaged regularly and continuously in the analysis of specimens of the waters under investigation in this case?

A. Yes, sir.

Q. You obtained the averages which you have given this morning by the use of the process of adding up the results as to each sample and dividing it by the number of samples?

A. Yes, sir.

Q. Do you consider a water having the following constituents potable, namely:

Free ammonia,	.217
Nitrites,	.013
Albuminoid ammonia,	.676
Nitrates,	.6 ?

A. No, sir.

Q. On what account?

2831 A. Because the free ammonia there has gone beyond .2
and the nitrites are up in the second decimal place, whereas, potable water shouldn't have free ammonia very much above .1 and in fact, if the nitrites are measurable at all, we usually condemn the water; but we see here in the figures you have given us .013. That is very high nitrites.

Q. I don't want an argument at all; I asked you in what respect?

A. On account of the very high free ammonia and the very high nitrites.

Q. Do you consider the albuminoid ammonia?

A. Of very little value in determining the character of these waters.

Q. Are they of any value in determining a sample of water without reference to this case or a history of the water?

A. Of a little value.

Q. Was the water analyzed as taken from the intake during the month of February, 1900, an absolutely unpotable water, unfit for human consumption?

A. Yes, I should condemn that water as unfit for drinking purposes.

Q. Would it of a certainty, poison inhabitants and animals, people and animals having partaken of it and render it unfit for manufacturing and agricultural purposes?

2832 A. It would not necessarily make it unfit for agricultural and manufacturing purposes, but it would probably cause disease if used for drinking purposes; perhaps not in persons of robust constitution, but very probably in persons of weak constitution, or children. Persons that are weak would probably suffer.

MR. JOHNS: I move to strike out the answer as not responsive and ask the reporter to read it again, and request that an answer directly be made.

Q. (Question repeated.)

A. Not with certainty, I would say.

Q. From what places were the samples mentioned as taken in April, 1900, to June, 1901, on page 3 taken?

A. These samples were taken at the St. Louis Intake, or the Intake of the St. Louis Waterworks.

Q. Would water containing the following ingredients, namely:

Free ammonia,	.150
Nitrites,	.009
Albuminoid amomnia,	.880
Nitrates,	.6

of a certainty be unfit for human consumption?

A. Not with certainty.

Q. Would such water of certainty produce disease in either animals or human beings?

2833 A. It will probably produce disease.

Q. Upon what account?

A. On account of the large amount of sewage matters in it, as indicated by the proportions of free ammonias and nitrites.

Q. That would be because of the presence of germs in that sewage, bacilli?

A. I suppose so.

Q. If there were no pathogenic germs in that sewage, could you tell anything about the probability of its producing disease?

MR. JEFFRIES: I object to the question because the witness is not qualified as a bacteriologist?

A. I don't know.

Q. MR. JOHNS: Well, a chemist considered of himself, is not supposed to know anything about bacteriology.

A. No, sir.

Q. It is the bacteria in the sewage which produce disease, isn't it?

A. I don't know.

Q. The chemical constituents named here in the proportion in which they were named in the former question, would not produce disease, if the water was used for drinking?

A. They might.

Q. Considered of themselves now, and solely as chemical
2834 constituents?

A. These figures that the chemist obtains show that there are in the water nitrogenous materials and nitrogenous materials are of animal or vegetable origin and they furnish the food for the growth and development of disease germs.

Q. I am asking you to exclude anything from your mind and from your consideration except the mere fact that the waters contain the constituents named in the former question and eliminate from your mind any other consideration in that and answer this quesion: Would such chemical constituents produce disease in a human being if such water was used for drinking purposes?

A. These constituents which we have, are not in the water as such, they are chemical compounds that have been gotten out of the water by chemical transformations. For instance, we report chlorines so many parts per million. We don't mean by that that the chlorine is there as chlorine. We report free ammonia so many parts per million. We don't mean that it is there free as ammonia; it is there in combination as ammonium carbonate, or ammonium chloride and when we say albuminoid ammonia, we simply mean ammonia that has been evolved by acting chemically upon this water, freed albuminous substances in the water.

MR. JOHNS: I am very much obliged to you for the lec-
2835 ture, and I move to strike out the answer as irresponsive
and ask that the question be re-read and I demand a direct
answer to the question.

MR. JEFFRIES: I submit that the witness has answered the question in an intelligent way and directly.

MR. WOERNER: Without a lecture.

Q. (Question repeated.)

A. I don't know.

Q. MR. JOHNS: Do you know anything personally as to the 11 analyses of water taken from the Missouri river above its mouth from September 2nd, 1899, to December 4th, 1899?

A. No, sir.

Q. Do you know what time elapsed from the taking of those samples until their analysis, the season of the year in which they were taken or the point in the river at which they were taken?

A. Only in so far as they are recorded on the sheets that I have examined.

Q. On the sheets that you examined were the solids in solution and in suspension given for those samples?

A. Yes, sir.

Q. Was the oxygen consumed given?

A. Yes, sir.

Q. The chlorines given?

2836 A. Yes, sir.

Q. Why did you not give the averages as to those?

A. Because it would have lengthened this statement very much and because those values are of less importance in judging of the sanitary character of the water.

Q. Are they of any importance as to the Missouri river?

A. The chlorine is of no importance, and the solids in suspension and in solution are of no importance, or of very little importance in arriving at a knowledge of the sanitary character of the water.

Q. Why is the chlorine not of any importance?

A. For the reason that the Missouri river water is highly charged with chlorides which is of mineral origin.

Q. Have you any personal knowledge as to that, as to the mineral origin of it?

A. Only in so far as the analyses show this water comes from the Kaw river.

Q. Have you any personal knowledge as to the Kaw river?

A. No, sir.

Q. What those results show to you as a chemist, independent of the consideration of this case, from such results as you have given, could you say whether that water was potable or unpotable?

2837 A. Yes, these results enable me to form an opinion of the sanitary character of this water.

Q. Well, what is that opinion?

A. That it is a fair drinking water, not above suspicion, but still it is drinkable.

Q. And you come to that conclusion without reference to the solids in solution or suspension, or the chlorine or oxygen consumed?

A. Yes, sir.

Q. And from those four items alone, you are enabled to form that opinion as an impartial chemist?

A. Yes, sir.

Q. In the examinations made by you of eight samples, did you determine the amount of solids in solution and suspension and the chlorines and oxygen consumed?

A. Yes, we determined the total solids—excuse me—we determined all of those but we didn't determine the solids in solution. We determined the total solids and the chlorine and the oxygen consumed.

Q. That is, in your data you determined the total solids?

A. Yes, sir; the total solids include those in suspension and those dissolved.

Q. And because they were not necessary to a consideration of the potability of the water you omitted them from this statement?

2838 A. Yes, sir; and because they would have cumbered this report with an unnecessarily large amount of figures and made it difficult to compare the same in these forms of nitrogen in every case.

Q. Which was the stronger consideration in your mind, the incumbering of the record, or the in-utility of the omitted elements in the making of the table?

A. The in-utility of the omitted elements?

Q. Referring to the sanitary condition of the Mississippi river between August 3rd, 1899, and December 4th, 1899, having free ammonia .107; nitrites .004; albuminoid ammonia .622, nitrates .5; is that water potable?

A. I should say that was unsanitary water and water that had reached the limit. It shows so much impurity in that water that it ought not be used for drinking purposes.

Q. Would you consider water, having the following parts, namely: Free ammonia .107, nitrites .004, albuminoid ammonia .622 and nitrates .5 a potable water?

A. No, sir.

Q. Now, that was the average condition of the Mississippi river as given in your tables, before the opening of the canal?

A. Yes, at a point above where it mixes with the Missouri.

2839 Q. Would you consider water having the following constituents free ammonia .069, nitrites .002, albuminoid ammonia .503, nitrates .3 a potable water?

A. Yes.

Q. Why, in putting in the average values for the Mississippi river above the mouth of the Illinois, did you put in the chlorine 6.0 when you have omitted it in all other tables and estimates made here?

A. Because, afterwards I found that I could get the chlorine for comparison in the Illinois river with the Mississippi.

Q. Well, you could have got the chlorine in the Missouri for comparison with the Illinois, couldn't you?

A. Yes, sir.

Q. And the chlorine from the Missouri for comparison with the Mississippi also?

A. Yes, sir.

Q. But you did not?

A. It wouldn't have helped us any.

Q. But it does help in the case of the Mississippi?

A. Yes, I think it does.

Q. Very little?

A. Yes, sir.

Q. Now, why does it help in one case and not in another?

2840 A. Because where a stream is contaminated with salt, rock salt, of course, the chlorine is no indication of sewage pollution, but where you have a stream that is not contaminated in that way a high chlorine indicates sewage, because all food matters contain a good deal of salt. Salt is used for seasoning food and we find it therefore in large quantities in sewage.

Q. Now, you assume in defense of the Missouri river, that its chlorines are entirely from mineral deposits in the river in Kansas?

A. No, sir; not entirely.

Q. Well, very largely?

A. Yes. There is so much there that the chlorine is no longer of service to us in judging of the amount of pollution in the water.

Q. You wouldn't admit that any portion of the chlorine in the Missouri river showed the presence of sewage in the Missouri river?

A. Yes, sir.

Q. What portion do you think in the Missouri shows the presence of sewage?

A. I couldn't say; I don't know.

Q. You have no idea?

A. No idea.

2841 Q. As a chemist and without reference to this question, if you had been called upon to analyze a sample of Missouri river water not knowing that it was Missouri river water and not knowing that you were a chemist of the City of St. Louis, would you have said considering the high chlorine in that sample that it was potable water?

A. I would have been inclined from the high chlorines to condemn that water as unpotable.

Q. The average values which you have stated here in all instances are taken or obtained in the usual way by the addition of the results of all samples taken and dividing by the number of samples?

A. Yes, sir.

Q. Have you done this work yourself, of obtaining these averages?

A. Yes, sir.

Q. These are the results of your own personal examinations, and the evidence introduced here, the tables introduced?

A. Most of them. In a few cases like this large table, in the beginning I have taken the averages that were made by the city chemist and published by him in the report of the three hydraulic experts that were appointed by the mayor of St. Louis to investigate the water supply.

Q. What samples or which table is that?

A. That is the table on page 3.

2842 MR. WOERNER: You had better have the record state that.

A. They were taken from the report on the water supply for the City of St. Louis by the Commission of Hydraulic Engineers in 1902. These are the monthly averages of themselves and I didn't figure out those. I took them as here published.

MR. JOHNS: If a consideration of the chlorines in the Missouri was not necessary to you as a chemist in determining the potability of the Missouri river water, why do they become necessary to you as a chemist in the determination of the potability of the waters in the Illinois river?

A. Because chlorine is generally used as one of the means of judging the potability of water.

Q. And yet you omitted it in the Missouri river samples?

A. Yes, sir.

Q. And the Missouri river conclusions?

A. Yes, sir; because the local history—if we had known that the Illinois river was fed by streams that carried large quantities of salt we shouldn't have been able to use the chlorine there.

MR. JOHNS: When these tables were made up with reference to a consideration of the circumstances of a particular case, they were not made up with reference to the consideration of the potability or unpotability of the water itself?

A. They were simple averages drawn from the recorded 2843 analyses in the possession of the Health Department of the City Chemist's office of St. Louis and the Washington University.

Q. Were they made up with reference to the consideration of the facts in this particular case, or were they made up by you as an impartial expert simply to draw conclusions with reference to the potability of the water?

A. They were drawn up by me in an impartial way for the purpose of satisfying myself as to what the conditions of the waters were at those stated times.

Q. But you took no consideraion of the chlorine in one river and you did in the other two. Did that arise from an impartiality in your mind, do you think?

A. Well, it seemed to me there was no use in putting the chlorine in, in the case of the Missouri river because it wouldn't help us any; it would simply cumber the report to put that in; it was of no value.

RE-DIRECT EXAMINATION, by Mr. Woerner.

Q. Professor, I want to ask you this question. You say that you did not consider the chlorine as an element in determining the potability of the water of the Missouri river because you attributed that chlorine to mineral origin and not to vegetable or animal?

A. Yes, sir.

2844 Q. Now, isn't it a fact, independent of any knowledge as to the origin of the chlorine, that the water contains high chlorine and low ammonias and low nitrates or an absence of nitrates, that it shows that the chlorines are not attributable to animal or vegetable origin, but must be attributed to mineral origin?

A. Yes, sir.

Q. And you found those conditions present in Missouri waters?

A. I did.

Q. And that did not apply to any of the other streams?

A. No, sir.

Q. So that if you knew nothing about the chlorine in the Missouri, coming from the Kaw river or from any other mineral source, you would have still come to the conclusion that they were attributable only to mineral salt sources?

A. Yes, if the ammonias are low. If the ammonias and nitrites are law, and if we find all forms of nitrogen low, low nitrites and low nitrates, then find high chlorine, the water is no longer contaminated and it may show that the water was at one time contaminated, but the forms of nitrogen have been removed and while the mineral matters may be high, the chlorine might be high, it would in all probability come from salt layers or salt springs.

2845 Q. And if the chlorine could be attributable to animal or vegetable origin, then you would say as a chemist that the nitrites and the free ammonias must be correspondingly high?

A. Yes, sir.

Q. And if they are not, it shows that they did not come from sewage pollution?

A. Yes, sir.

Q. And that is the condition of the Missouri river?

A. Yes, sir.

Adjourned until 2:00 p. m. same day, Saturday, April 4, 1903.

2846 Southern Hotel, St. Louis, Missouri. 2:00 p. m., Saturday, April 4, 1903. Continuation after recess.

Present, the Commissioner and same counsel representing the respective parties.

PROF. EDWARD H. KEISER resumed the stand for further re-direct examination, by Mr. Jeffries, and testified as follows:

Q. Professor, I will ask you to state what that piece of paper is (handing same to witness).

A. These are the printed results of chemical analyses of the water taken from the distributing well and the settling basins of the St. Louis Waterworks, in the year 1893. This paper is from the Annual Report of the Water Commissioner for the year ending April, 1894—M. L. Holman, Water Commissioner.

Q. And is the same paper that you testified concerning in your answer to questions propounded by Mr. Johns this forenoon?

A. Yes, sir.

Q. I will ask you if you have a copy of that report in full?

A. I have.

2847 Q. And that is one of the pages taken from the official report?

A. Yes, sir.

Q. Now, this morning you said something about the report containing the system used in making the experiments or the examinations or analyses of the water?

A. Yes, sir.

Q. Is that contained in the report?

A. Yes, sir; the methods used in arriving at these figures are described in the pages succeeding this in the same report.

Q. Can you get a copy of the pages containing the report?

A. Yes, sir. I simply removed one page from it. The other pages follow this, and I have those.

Q. Now, what do you say with reference to the system used in ascertaining those results, as to its being a proper system to follow in the examination of water?

MR. JOHNS: I object to the question as not re-direct examination and as incompetent—that it is a subject upon which it is incompetent to express an opinion.

A. I have read the methods described in this report and they are the usual standard methods used in analyzing water.

Q. Now, will you get a copy of the page containing those methods and bring it down here Monday morning?

A. I will. I have the rest of this that contains it. It is 2848 a bulky volume. I can bring it—the other pages, or bring the whole of it. I will bring the whole of it.

Q. Will you bring the book from which those pages are taken?

A. Yes, sir.

MR. JEFFRIES: Now, I will offer this page in evidence as complainant's Exhibit No. 36, with the privilege, Monday morning of introducing that page from the book or report of the Mayor for the year, in connection with the pages of the book as containing the system or plan used in arriving at these results.

Said paper received in evidence and marked as requested.

MR. JOHNS: I object to the paper with the proposed addition, as it is not a public record and not such a publication in any event as becomes competent evidence.

Q. MR. JEFFRIES: I will ask you to examine those two papers and state what they are?

A. The first of these two gives the results of twenty-one analyses of samples of water—of the St. Louis water, made from December 15th, 1892, to April 20th, 1894, in the chemical laboratory of Washington University.

Q. What kind of water was it?

A. That was the tap water—or the St. Louis drinking water.

2849 MR. WOERNER: Well, were you familiar with those yourself?

MR. JEFFRIES: Who made this tabulated statement?

A. These were made by my predecessor, who was professor of chemistry in the Washington University at that time. His name was Dr. Charles Sanger, now professor of chemistry at Harvard University.

Q. And was a record kept of the examinations—kept there in that laboratory?

A. In the laboratory record book.

Q. And that is copied from the record book, is it?

A. This is copied from the record book.

MR. JEFFRIES: Now, I offer this record in evidence as complainant's Exhibit 37, with the privilege of respondents to examine the original book from which it was copied, on Monday morning.

MR. JOHNS: We object to the admissibility of the exhibit as evidence because it is not such a matter of evidence as can be identified or proved by comparison, and that the record from which it was copied is not a public record.

Said document received in evidence and marked as requested.

Q. MR. JEFFRIES: Is it possible to get the original record and leave it in this case?

MR. JOHNS: Don't misunderstand me, gentlemen; I am 2850 not objecting to it because it is a copy. I have not said so. If the original paper was here I should object to it in the same way.

MR. WOERNER: Let the record show then that the objection is not based on the ground that it is a copy.

MR. JOHNS: The objection is not that it is a copy of some entries in that book, but is that the entries in the book, and the book itself, is not such record as is admissible under the rules of evidence, in any legal controversy.

Q. MR. JEFFRIES: This tabulated statement as contained on that sheet and as contained in the original record in the laboratory of the Washington University were made by your predecessor, you say?

A. Yes, sir.

Q. And represent the analyses of water taken from the tap?

A. From the tap.

Q. In the laboratory of Washington University—hydrant water of St. Louis.

Q. And the record is kept in your laboratory by the Board of Trustees of the University, and under their direction?

A. It belongs to the university; it is a university record.

Q. Now, I will ask you to examine this sheet and state what it is, and what it represents?

2851 A. This sheet contains the results of daily analyses of water from the Missouri river at Fort Bellefontaine, the samples having been taken from January 23rd, 1900, to February 1st, 1900. They were made under my direction in the chemical laboratory of Washington University.

Q. And from water taken where?

A. From water taken in the Missouri River at Fort Bellefontaine.

Q. Is this a copy of the record contained in the laboratory?

A. No, this is the original record.

Q. This is the original record?

A. These were made under the direction of the City

Q. Which side it was on?

A. Yes, and the velocity of the wind varied probably from about 5 to 12 miles an hour.

Q. Now can you give the names of the men that you selected and who were actively engaged in taking these observations from Chicago to St. Louis?

A. C. V. Mersereau, and T. F. Reed were the assistant engineers from Chicago to Peoria, and J. E. Gibson and F.
2880 J. Brown from Peoria to Grafton. They are all connected with the St. Louis water department, and were detailed for these observations.

Q. Is that all of them?

A. That was all except the boatmen, etcetera, that were hired and had no part in the technical observations that we made.

Q. Now then, from these men that you have just named, you got this data with reference to the flow of the river along these particular places?

A. Yes, from Chicago to Grafton.

Q. State whether or not the work was done continuously from day to day with the exception of suspending the work during the night, and as you stated a moment ago?

A. There was no interruption through more than a night and the hours of early morning and late afternoon, except one day where a very severe storm on the upper Illinois prevented a prosecution of the work there; that day was the 24th of March.

Q. You stated, I believe, Professor, that these floats were made under your personal supervision?

A. Yes sir.

Q. As a civil engineer?

A. Yes sir.

Q. State if you know from your personal observation in following these floats down the Mississippi River from Grafton to the Intake, which side of the river they seemed to fol-
2881 low or what particular point in the river did they follow?

A. The floats were placed in the lower end of the Illinois River in such a way that they spread across the river; one in the center, one about half way from this one to the right bank, and one about half way from the center one to the left bank.

Q. That was in the Illinois River?

A. That was in the mouth of the Illinois river. As they flowed into the Mississippi River they moved closer and closer to the Illinois shore of the Mississippi River and in a general way from the Illinois river to below the mouth of the Missouri they were more or less close to the Illinois shore. Sometimes, in the extreme, getting to the middle of the Mississippi River, but most of the time being within three or four hundred feet of the Illinois shore. At about two miles above the waterworks intake for instance, the floats were quite close to the Illinois shore; perhaps about 50 feet from it, but from this point on down to the waterworks intake the floats rapidly left the Illinois shore, reaching the middle of the Mississippi River and finally passing the waterworks intake between the Intake and the Missouri shore.

Q. All of them?

A. Yes sir, and perhaps—and somewhat closer to the Missouri shore than to the intake. The distance from the
2882 Missouri shore to the waterworks intake is about 1500
feet and from that I judge that the floats passed the intake about 700 feet from the Missouri shore.

MR. JEFFRIES: We are through with the witness now with the exception that we may want to introduce one of the floats when it gets here.

CROSS-EXAMINATION BY JUDGE JOHNS.

Q. Does the stage of the water in the drainage canal above Lockport remain pretty constant?

A. I understand so.

Q. The stage of the water in the Desplaines River is very fluctuating, is it not?

A. Yes sir.

Q. Are there any gauges indicating the stage of the water in the Desplaines river?

A. Yes sir.

Q. Where?

A. I saw one at Lockport, just below the Bear Trap Dam, when I was at Lockport, after these observations were taken, in an attempt to get the readings of the gauge for that month. I understand there are gauges at Joliet, but I did not personally see them there.

Q. Do you know anything about the stage of the Desplaines River when the floats were put in there? 2883

A. Gauges were read by these engineers as they passed them, wherever they saw them, but beyond that I know nothing about it. I have been unable to get such readings.

Q. Have these gauge readings been furnished to you by the observers?

A. They are in the field note books which I neglected to bring this morning.

Q. They are not in your notes from which you have been refreshing your memory?

A. No sir.

Q. So as to the time that these floats were in the Desplaines River, you have no knowledge now of the stage of the river?

A. No exact knowledge, no sir.

Q. Do you know as a matter of fact whether the river was high or low?

A. It was high.

Q. Now there are gauges at various places upon the Illinois River?

A. Yes sir.

Q. Do you know at what places?

A. There are gauges at all the locks; there are also gauges of which I have records, at Peoria, Beardstown and Grafton.

Q. And at various locks?

2884 A. Yes and I am confident there are others, but I don't know definitely about them.

Q. Now what was the stage of the Illinois River from the time that the floats were placed in it until the end of the experiment?

A. In general, the Illinois River was high.

Q. Was it very high?

A. Yes sir.

Q. The bottom lands and the overflowed land along the Illinois River was very extensive, was it not?

A. Yes sir.

Q. The river was sometimes four or five miles wide in very high water?

A. It may be.

Q. From water line to water-line?

A. Yes sir.

Q. Varying of course with reference to the proximity of the high land to the river?

A. Yes sir.

Q. But at times during this experiment the river was out of its banks and overflowing the bottom lands, was it?

A. A great many of them.

Q. Well, the ordinary banks of the river at all places were overflowed with water?

A. Yes.

Q. The water extending out into the bottoms?

A. Yes sir.

2885 Q. Now in the Desplaines River how many floats were put in at one time?

A. I believe five; one had been lost in the drainage canal.

Q. Were they put in at the same place and at the same time?

A. Yes sir.

Q. So that you had floating down the Desplaines River under observation at the same time, five different floats?

A. Through a portion of it, but from time to time the floats were lost so that before reaching the mouth of the Desplaines river I believe that one or two more had been lost.

Q. When you placed them in the Desplaines river what was the plan upon which they were placed?

A. The plan was to distribute them across the channel portion of the river, to place them abreast of each other opposite a certain point, to distribute them across the channel of the river.

Q. By channel you mean that part which is the swiftest moving of the water?

A. Yes sir, as near as could be judged.

Q. Now did you have in the Desplaines river floats of different lengths?

A. Yes sir.

Q. One, two and three feet?

A. Yes sir.

2886 Q. And you continued that also in the Illinois River?

A. Yes sir.

Q. Where were the longer floats placed, in the center or on the sides of the channel?

A. As a rule the longer ones were placed in the deeper water.

Q. In the center of the channel?

A. Yes sir.

Q. Well, whether or not—was that your instructions for the Desplaines?

A. I believe in the oral instructions I spoke of that matter to those engineers before I sent them out, but nothing in regard to that occurred in the written instructions.

Q. Is there anything in regard to placing the floats and the length of the floats in your field notes from your engineers?

A. The numbers to identify the floats are given in each case,—yes; so that it can be told where the floats of different depths were put with reference to each other and with reference to the shore in a general way.

Q. Do you know whether after those floats were placed in the water on a cross-section of the river they separated wider than when placed—or whether the tendency was to come together toward the middle of the channel?

A. I understand that the general tendency was towards separation although there was nothing very marked to be observed in that connection.

2887 The stage of river throughout our observations in the Desplaines and the Illinois being in a condition of overflow, caused them to rather seek the banks.

Q. The current outward?

A. Yes sir.

Q. During that time was it found they were aground?

A. Quite often.

Q. And when that was done they were released and taken back to some deeper point?

A. Taken back.

Q. Did those floats in the Desplaines river keep abreast of each other if they were floating rapidly?

A. That would depend largely on the wind, sir, whether they would keep abreast of each other or not. In general they would keep abreast of each other.

Q. Which one would advance more rapidly?

A. That would depend whether the wind was more up-stream or more down-stream. In general the wind was (more than otherwise) up-stream or had a component up-stream, which would affect the shorter float more and hold it back.

Q. Have a greater effect on the shorter float?

A. Yes sir.

Q. The float having the shorter chain from the visible part to the gauge below—what do you term the lower part of the float, having the flanges?

2888 A. Well, it has no distinct name. I generally speak of it as the vanes of the float.

Q. Would the direction of the wind have a considerable effect upon the direction in which the floats went down the river?

A. I couldn't say. It would considerably affect it would have an effect and of course the amount of it would depend upon the velocity of the wind as well as other things, but mainly upon that. The effect would be small compared with the effect of the current of course, but it would have an effect, a certain effect.

Q. You had no way of determining how much of an effect it had in varying the course of the float?

A. No experimental way. Of course it was generally noticed that during a half a day or a day's run, that the floats would work toward the leeward side of the river. If the wind is across stream during a number of hours' run, greater or less, depending upon the velocity of the wind, the floats in general will be influenced in the direction of the wind to an extent.

Q. The visible floating part was it rigid or would it revolve and swing in the water?

A. It was rigid as far as—it was not a pliable thing, but you see the chain would allow the upper part to move as though on an axis, perfectly well. That is to say, I suppose the question refers to that metal flag that was upon it?

Q. I am asking you first as to the float, the body of the
2889 float itself; was it attached to the chain by a swivel or in any way so that it could by itself revolve?

A. No sir, there was no swivel. The chain was linked so that the link permitted a horizontal movement.

Q. The flag above the float was how high?

A. The top of it was about twelve inches above the top of the cone.

Q. And the top of the cone was above the water how much?

A. Above the water level about four inches.

Q. So that the top of the flag would be about sixteen inches from the surface of the water?

A. Yes sir.

Q. How large was this flag?

A. Four inches square.

Q. Of what material?

A. Sheet iron.

Q. On what kind of a staff?

A. Stiff wire.

Q. Ordinary wire?

A. Yes sir.

Q. Was it fixed firmly to the staff or would this flag revolve?

A. No sir, it was fixed firmly to the staff.

Q. I don't know that I understand you. Was the flag a square piece of metal?

2890 A. Yes sir.

Q. Four inches square?

A. Yes sir.

Q. And painted?

A. And painted a color and with a number to identify the float.

Q. Now were the observations of your engineers kept with reference to the numbers of those floats?

A. Yes sir.

Q. And the field notes were mentioned by number?

A. Yes sir.

Q. When a float went aground, what was done with it?

A. It was pulled out and put in the channel either opposite the point where it went aground if it was not too far back, but if it were too far in the rear of the general group of floats, it was simply pulled out and carried ahead and put in with the group in the channel.

Q. Now did they differ very considerably in the distances which they would travel in a given time?

A. Yes, quite considerably.

Q. On what account?

A. Well on various acounts; partly on account of the different depths of the vanes; partly on account of some of them in the same group being deflected toward the shore and others
continuing in the channel, and partly because of driftwood
2891 that would interfere with them sometimes, and other similar reasons.

Q. Is it not a fact as a general observation that the floats nearest the center of the channel traveled most rapidly?

A. Yes sir.

Q. And the floats nearer the shore were much slower?

A. Yes sir.

Q. So that the fact is that the center of the channel, the current of the river, wherever it may be, moves according to these observations much more rapidly than the water does on the side?

A. Yes, there is a very distinct difference.

Q. Could you tell how much difference from the observations and reports which were made to you as to the current in the center of the channel of the Illinois River and at the sides?

A. No sir. It is a very noticable difference in all hydraulic observations of the kind, but it is a very variable difference at different portions of the river, depending on a great number of things.

Q. Your statement that the entire time from Lockport to the Intake, or to Grafton, rather, was nine days and three minutes?

A. Yes sir.

Q. Would that be for the center of the channel?

A. That would be—that time is the aggregate time which
is determined by the time occupied from the putting in of
2892 the floats in the current abreast of each other, and fairly
close together, to the time when the leading of these floats reached the point at which work was suspended for that day.

Q. So that whenever you have mentioned a time here that the float was taken out, it was the time of the arrival of the most advanced float at that point?

A. Yes sir.

Q. Then the total time of 9 days and three minutes, is the fastest time that these floats made down the Illinois River?

A. Yes sir.

Q. Could you tell or had you any knowledge of how rapidly the current flowed if at all, at the side of the banks of the Illinois River?

A. Well, I know nothing definite about that except for one portion between Peoria and Pekin, where I was obliged, or where I did start a party and was obliged to take a trip in order to find a boat, when I simply observed a very slow current at the side of the banks of the stream; how slow I couldn't say. I haven't any doubt it was less than a foot a second and very much less.

Q. Less than a foot a second?

A. Yes sir. It was observed from along the line, and is nothing definite at all.

2893 Q. So that all your observation has determined is the quickest time of the most swiftly flowing water from Lockport to Grafton?

A. Under conditions existing at the time the observations were made, yes sir.

Q. Now isn't it true that the current of the Illinois River at the time of these observations was very much swifter in its channel than at the ordinary stage of the river?

A. I suppose it is.

Q. Is it not true that it is very much swifter than at the low stage of the river?

A. Undoubtedly.

Q. Now all you know from these experiments as to the time for the flow of water is at a very high stage of the Illinois River and the fastest time that the floats could make?

A. I would say as to all except the last phrase. As an engineer I could not agree that it is the fastest time that the floats could make under any stage of the river.

Q. I didn't intend that you should gather that meaning from my question. It is the fastest time that the floats under the observation of yourself and your assistants, did make from Lockport?

A. Yes, it is the minimum time over the course covered.

Q. Do you know whether there had been all over the valley of the Illinois, very heavy rain-falls immediately preceding this experiment?

A. I understand that is the case, yes.

2894 Q. Did you select this time for the experiment with reference to that fact?

A. About a week before entering upon this work I was told that these facts were very desirable in connection with the investigation and suit, and I was asked to make experiments as speedily as possible and did so. I had not the information of the desire to have them until a few days before they were entered upon.

Q. Now what was the stage of the Mississippi River at the time you followed the floats from Grafton to the Intake?

A. In an approximate way the Mississippi River was at about half stage, half its flood stage.

Q. The guage readings were about 24 feet here, were they not?

A. Nearly, yes,— between 23 and 24 at the time the observations were made from Grafton.

Q. What do you understand by a guage?

A. A gauge is a staff or other appliance on a river bank placed there for the purpose of indicating the stage of water in the river.

Q. We have been using the term here in a little different sense. When we say that the river is 24 feet on the gauge; that means 24 feet above what point?

A. It doesn't always mean the same thing, sir. It means that it is simply 24 feet above the zero reading of that 2895 gauge. Now the zero reading may be low water and may not.

It is generally the desire, and is certainly better to have the zero mean extreme low water reading, but it isn't always the case on gauges.

Q. Is it the case at St. Louis?

A. The lowest water known at St. Louis was 2.5 feet below the zero of the St. Louis gauge.

Q. Now when you say that the Mississippi River was at about half stage, do you mean to say that the Mississippi River at St. Louis rises to a height on the gauge of 48 feet?

A. No sir. I said that was the approximate condition for this reason; while the St. Louis gauge read 23.3 the highest water we have had here was 41.4 feet, less than double, while at Grafton the gauge reading on that same day was 16 feet and the highest water known there was 37.8, and more than double; so that it is the local condition, the width of the channel and other such things that control; so that I cannot state precisely whether the river is half height, or two-thirds height, or six-tenths height, or what not.

Q. Now what part of the river, of the channel of the river does the water flow most swiftly in,—the center is the place I presume?

A. In a straight piece of river. If it is curved, it is swifter toward the concave bank and sometimes very close to the
2896 concave bank.

Q. And sometimes right up against the concave bank?

A. Well, not exactly, but very close to it.

Q. Now commencing at the surface, is the water flowing on the surface more rapid than it is two feet below? Or more slow?

A. In general it is more slowly. If there is wind down stream sometimes the surface has a maximum velocity under the influence of the wind, but usually the maximum velocity is at the depth, where there is no wind, at the depth of one-fifth or one-sixth below the surface, or somewhere in that vicinity. It is not the same for all streams but that is the general fact.

Q. When you say one-fifth or one-sixth, you mean one-fifth or one-sixth of tthe perpendicular depth from the surface?

A. Yes sir.

Q. Not from the bottom?

A. No sir, from the surface.

Q. Water below that point, the swifter flowing, of course, flows more slowly?

A. Yes sir.

Q. And in the channel most slowly at the bottom?

A. Yes sir.

Q. Have you any means of determining, as an engineer, assuming the flow of the water at its swiftest point to be, say six feet a second, what would be the flow of the water at the 2897 bottom if its perpendicular depth was twenty feet, or any other depth?

A. No sir, there is no way of determining that. It depends not merely on the slope of the river itself, but on the general direction and character of the river, whether it is comparatively straight, or very crooked. That would depend particularly upon the character of the bottom, whether it is mud, sand, rock or gravel, or very rough or very smooth; there is no way to do it.

Q. Whether it is clogged with obstructions or free from them?

A. Yes sir.

Q. Now the longest chain you used on the float in the Illinois River was three or four feet?

A. Three feet.

Q. And the shortest was one foot?

A. Yes sir.

Q. Where was the longest float placed,—near the center of the river; was that your instruction?

A. That was the general intention, but that was left a good deal to the discretion of the engineers that were observing it. It was a point of such minor importance that I didn't consider it worth while to issue any special instructions on the point. For instance, any delay that might be caused by acceding 2898 to such requirements would more than compensate for securing it.

Q. Your object was to obtain the approximate length of time it would take a float to travel from Lockport to the Chain of Rocks?

A. Yes, or really from the Chicago River.

Q. What kind of a day was it when you followed them on the Mississippi River?

A. The floats were started at 6:56 in the morning and passed the intake at six minutes after six in the evening.

Q. As to the character of the day?

A. The day was somewhat cloudy and somewhat windy. Enough to cause that part of the float sometimes to be entirely out of water and sometimes entirely submerged.

Q. And the flag sometimes submerged?

A. No sir, simply the buoy part. The flag and above the wire staff was practically always out of water. There was a jumping of the float—an apparent jumping of the float of about eight inches. That would give an idea of the conditions perhaps.

Q. What was the direction of the wind that day?

A. I judged from the way it seemed to vary with reference to our course, that it was practically from the southeast all day.

Q. These floats hugged the Illinois shore down to a point
2899 a mile or two above the entrance of the Missouri River?

A. No sir, below the entrance of the Missouri River to two miles above the waterworks intake.

Q. Two miles above the waterworks intake?

A. Yes, they were never more than half way across above Alton.

Q. Then above the intake they started across the river?

A. Yes sir.

Q. All of them?

A. Yes, there were only two then. We started with three but a chain parted and one was lost below Alton. I think from Alton down there were only two.

Q. How far out from the bank on the Illinois shore were those floats when they started toward the Missouri?

A. About two miles above the intake both floats were about 50 feet from the Illinois shore. That is, this two mile point was between the mouth of the Missouri and the intake.

Q. How long were the chains to these two floats?

A. One was six feet and the other four.

Q. Did they travel together?

A. No sir.

Q. How much did they separate?

A. Do you mean with reference to the shore or with reference to the speed?

2900 Q. With reference to each other first?

A. Will you allow me to read the field-notes?

Q. Read them and refresh your recollection, if you see fit.

A. I recollect very plainly their action with reference to each other, as far as the distance from the shore is concerned, but how far one was ahead of the other I don't remember. (Witness reads notes) I am wrong in what I just said, sir. The floats were about 50 feet from the Illinois shore at a point where the Missouri River enters the Mississippi. A mile below this point both floats were three or four hundred feet from the Illinois shore. Two miles below this point the red No. 5, which is the six foot float, was 200 feet from the Illinois shore and the four foot float was 400 feet or thereabouts, from the Illinois shore. In passing the upper end of Chouteau's slough, still nearer the waterworks intake, the four foot float was 600 feet or thereabouts from the Illinois shore and the six foot float was about 100 feet in the rear and about 100 feet from the Illinois shore, and just below that the six foot float kept moving still further toward the left, and was about to pass at what is called by river men, the chutes, that is the pasage to the eastward of the island opposite the intake, and was pulled out of the water and put in again opposite, the four foot float which had not been
disturbed, and about 60 feet to the left of it. That is, 60
2901 feet toward the Illinois shore from the four foot float.
That is below the Madison Point light; and still the six foot float kept working off toward the left and moving toward those chutes (as they are called), behind the islands, to the east of them and was pulled out again and put in abreast of the four foot float about sixty feet toward the Missouri shore,—at this time, from it. From that time on they both kep on very closely together, the six foot float however, lagging behind, but with reference to the shore they seemed to keep, or work, toward each other and crossed opposite the intake at about the same distance from the shore. That is to say, the red was disturbed twice,—the six foot float was disturbed twice between Alton and the waterworks intake. The four foot float was not touched.

Q. Now the six foot float was taken out of the water and moved over toward the Illinois shore?

A. Moved away from the Illinois shore, because it seemed to be that if it had gone behind the islands, to the easward of the islands, it would have been lost to us.

Q. Then it was moved over toward the right?

A. Toward the right, yes sir.

Q. I understood you to say it was moved over towards the left?

2902 A. No, I said it had moved over near the Illinois shore, and placed the first time about 60 feet to the left of the four foot float.

Q. And that would be 60 feet nearer the Illinois shore?

A. This four foot one was farther from the Illinois shore than it (the six foot float) was when it was taken out.

Q. Now what are these things which you term chutes?

A. It is simply a high water channel behind the islands. At low water there is practically no flow and there is no channel there and when the water of the Mississippi rises it of course leaves its channel and flows on through this back channel on the Illinois shore.

Q. It was about to go into some one of these things when it was removed,—the six foot float?

A. Yes. So I placed no special import upon the action of that red float, the six foot float, because it was disturbed, it was taken out.

Q. Did it travel more slowly than the other one?

A. It did after it was put in the last time, near the waterworks intake, about a mile above the waterworks intake. For the first mile it moved more slowly. There were times when one would move more slowly than another, depending upon the circumstances, or the wind and the depth, probably, mainly.

Q. And the velocity of the current at the place where it was?

A. Yes, really, but affected by wind and depth.

2903 Q. When you say that the floats were close to the shore at a point where the Missouri River enters the Mississippi, you mean the north shore of the Missouri River, or the center of the river, or what do you mean?

A. I mean that the floats passed the mouth of the Missouri River, at the Missouri River point as it is called on the river, at about fifty feet from the Illinois shore, of the Mississippi River, that is, the left bank of the Mississippi River.

Q. The Missouri River was also a very high stage of water at that time?

A. The Missouri River at that time was at about a half stage.

Q. Well, at about the same stage as the Mississippi?

A. Yes sir.

Q. Twenty or twenty-five feet on the gauge?

A. This will give the indication. At the lowest gauge I could get on the Missouri on this date, the reading was 15 and one-half. This is at Hermann. The high water is 35.6, indicating very much the same thing as the stage of the Mississippi.

Q. Is there a water gauge at Fort Bellefontaine?

A. I think there is, but I didn't get the gauge. I have no reading for that, no sir.

Q. Was the Missouri River where it enters the Mississippi very wide at this stage?

2904 A. Yes sir.

Q. How wide would you say?

A. Well, at almost any stage not deducting the area occupied by the numerous islands, it is between three-quarters and a mile wide, probably, but part of this is taken up of course by islands.

Q. And the confluence of the two rivers produces strange effects in the currents there, doesn't it? For instance, did the floats circle any in the meeting of those waters?

A. No sir.

Q. They kept along steadily?

A. Very steadily. They were apparently so close to the Illinois shore that they were not affected at all directly, by the inflow of the Missouri River.

Q. And kept that position for a mile or two?

A. Well, from that point they began gradually and very slowly, but gradually, to leave the Illinois shore, or from that vicinity.

Q. Do you know whether there were dikes in the river along the Illinois shore opposite the mouth of the Missouri River and below that down towards St. Louis?

A. I don't know of any.

Q. You know nothing whatever as to the number or contion or position of dikes opposite the Mississippi River and on the Illinois shore practically to the chain of rocks?

2905 A. I cannot speak authoritatively on that point at all. I don't know of any such.

Q. And whether there are any or not you don't know?

A. No sir.

Q. If there were such dikes, would that effect the direction or velocity of the current for such a stage as you have described?

A. To an extent. The Mississippi dikes are always built for low water effects, and at this stage I can hardly see how such dikes would have any effect if they existed there, other than to retard the velocity of the floats, because the floats would be passing directly over them if they were there.

Q. Now how far above the intake itself did these floats pass in going over toward the Missouri shore?

A. It was a gradual movement entirely.

Q. Well, with reference to the current of the Mississippi River the intake is about on the edge of the Mississippi channel is it not?

A. Yes sir.

Q. How far with reference to the direction of the current above the intake, did these floats pass the intake itself?

A. I can explain that better perhaps by showing the platted course of these floats.

2906 Q. Well, if you can answer my question you may.

A. Well, I estimate that at about one-third of a mile.

Q. Now then, did they go clear over to the Missouri shore?

A. No sir.

Q. Did they pass the intake itself on the west side?

A. Yes sir.

Q. And between that and the shore?

A. Yes sir.

Q. Where did you take them out of the water?

A. Immediately below, as soon as I could get them after timing them as they passed.

Q. And both of the floats went over there?

A. Yes, one of them as I have stated, however, being removed and put in again, which destroys any significance that may be attached to it.

Q. How far is it from the mouth of the Missouri River to the chain of rocks?

A. I guess I will have to scale that off of the chart.

Q. Have you a general idea how far it is?

A. I should think five or six miles; that's my recollection of it.

Q. Five or six miles, you think?

A. Yes, that's my recollection as near as I can give it.

2907 Q. Now when these floats started across the river for the Illinois shore, how far were they north of the intake?

A. Up-stream from the intake?

Q. Yes, up-stream?

A. They were opposite the mouth of the Missouri. They were actually opposite the Missouri River point which is a point between the Missouri and the Mississippi as they come together.

Q. Well, that is the southern point.

A. It is the northern point, on the north side of the Missouri River.

Q. Of the Missouri River?

A. Yes.

Q. They were opposite the north side of the Missouri River when they started to move across the river?

A. Well, I don't know that they started immediately there. They were at that point, opposite the Missouri River point, when they were about 50 feet from the Illinois shore.

Q. Now they started to move away from the Illinois shore when they were about opposite what is known as the Missouri River Point.

A. I don't know that they started then. The first thing that I noticed was about a half a mile below that, or opposite really the mouth of the Missouri River. They were not so close to the shore, not so close to the Illinois shore as they were opposite the Missouri River point.

2908 Q. And when they were a mile below this Missouri River point they were 300 feet or so from the Illinois shore. Now did they continue to go in about a direct line across the Mississippi River?

A. Oh, no sir. From that point on down for some distance, the four foot float kept on at about the same distance from the Illinois shore, and the six foot float moved off toward it.

Q. Well, for how great a distance was that in feet or miles or fraction of miles?

A. Well in another mile or two the four foot float was somewhat farther from the Illinois shore, perhaps 600 feet and the six foot float was still closer to the Illinois shore or about 100 feet from it perhaps.

Q. How far below the mouth of the Missouri River?

A. My recollection is about three miles.

Q. About three miles?

A. That is just at Chouteau's slough. I can get that exactly if you care to have it.

Q. Well, in general terms it is about three miles below the real mouth of the Missouri when the six foot float was closer again to the Illinois shore?

A. Yes sir.

Q. And the four foot float was about 600 feet from the shore?

A. Yes sir.

2909 Q. How wide is the Mississippi River at that point between its normal banks?

A. I think it is about three-quarters of a mile. It appears to be narrower somewhere in that vicinity.

Q. Then the floats three miles below the mouth of the Missouri were not near the center of the channel?

A. No sir, not near the center of the river. I don't know where the channel is.

Q. Not near the center of the river?

A. No sir.

Q. Can you tell accurately the distance from Chouteau's slough to the intake?

A. I can in a moment.

Q. Will you please?

A. (Witness examines map). I have platted there the course of the floats as indicated by the notes. There is the Mississippi River (indicating). Here is the Missouri and there is the Missouri River point which I have described, and the black line shows the course of the float which was not interrupted, and the red line shows the course of the six foot float which was taken out and put in as indicated there.

Q. MR. WOERNER: And also shows the interruptions?

A. Shows the interruptions and shows everything just as it occurred. Here is the intake and here is where they crossed. 2910

JUDGE SPRINGER: What does this mean?

A. That is a sand-bar.

Q. Was it out of the water?

A. It was really an island. There were trees and the water was overflowing it. This is the chutes I referred to a moment ago. This is where the red one was heading for, and I didn't want to lose any so I simply took it out of the water.

Q. JUDGE JOHNS: Can you tell accurately the distance from Chouteau's slough to the intake?

A. It is practically four miles from Chouteau's slough to the intake by the course followed by the float.

Q. Now below the point where the six foot float was about to go into Chouteau's slough, there is a sand-bar or island?

A. Yes sir.

Q. In low or medium stage, it is quite a large island, isn't it?

A. Yes sir.

Q. And the general current of the river goes around to the left of the island as you go down the river?

A. Yes sir.

Q. And that is the general current at what time?

A. It certainly must be at low water when there is practically no flow here, and the course of these floats indicated it to be the case at medium stage.

2911 Q. If this red float had not been interrupted it would have gone down through Chouteau's chute, wouldn't it?

A. Through this chute as the river men call it. Probably it would. I was afraid of it.

Q. And if it had done so, it might have gone below and to the left as you go down the river, of three other islands or two other islands between that and the chain of rocks?

A. To the right, do you mean?

Q. Yes.

A. I think so; I presume so.

Q. Now may be you and I don't agree as to which is right—

A. I beg pardon, I made a mistake.

Q. To the left?

A. Yes sir.

Q. To the left as one is going down the stream?

A. Yes sir.

Q. That float might have gone to the left of three islands between Chouteau's slough and the intake if it hadn't been interrupted?

A. Yes sir.

Q. And at that time there was a decided current that way?

A. Yes sir.

Q. And in order to prevent its going that way you took it out of the water and replaced it in the main channel of the Mississippi?

2912 A. Yes sir.

ADJOURNED until 2:15 P. M., May 5th, 1903, to meet at the City Counselor's Office, in the City Hall.

City Hall, St. Louis, Missouri.

2913 2:15 P. M., Tuesday, May 5th, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

J. L. VAN ORNUM,

Resumed the stand for further cross-examination by Judge Johns, and testified as follows:

Q. What is the general direction of the Mississippi River from Chouteau's slough to the Chain of Rocks?

A. It is very crooked in that vicinity. Its flow at Chouteau's slough, as I recollect it, is about southwest, and from that direction there is a gradual curve, until at the Chain of Rocks I believe the Mississippi River flows nearly south.

Q. Its general direction is southwest from below Chouteau's slough to the Chain of Rocks, or is it west of south?

A. It is certainly west of south. I think the average direction might be considered something west of south.

Q. A southeast wind then would be blowing almost at right angles to the direction of the current?

A. I don't think at right angles, but very close to it. In connection with the map and in considering in my own 2914 mind that aspect of the case, I had arrows put in to indicate the direction of the wind, which would indicate on the map the relation to the direction of the flow at different portions of the river, all the way from the Missouri River down to where the floats were, to the Illinois shore, and to the waterworks intake, and as a resume and result of that I think it is fair to say that the average component of the wind which would affect a float in direction in right angles to the average direction of the current would be about 6-10 of the effect of wind if it were blowing exactly across the stream all the way.

Q. Well, is the general direction of the southeasterly winds across the Mississippi River from Chouteau's slough to the chain of rocks, an angle of about 60 degrees?

A. It might be. I can get at it quite closely if it is worth while by referring to that same map if you wish it.

Q. What is your opinion?

A. Well, I haven't looked into that so that I can't give a very close idea about that. I presume that would be a fair estimate.

Q. Now of all these observations of which you have testified, you personally conducted none except from Grafton to the chain of rocks?

A. No sir.

Q. You didn't assist in the making of the experiments, 2915 nor did you conduct those which were commenced at the highway bridge at Peoria?

A. Well, I conducted that to this extent: I started everything and did personally start the floats, but at that point left it to the charge of the assistants.

Q. So that all your knowledge or information of the floats and their speed and rapidity and the various happenings to them come to you from reports made by your employes?

A. Yes sir.

Q. As to the entire Illinois River above Grafton?

A. Yes sir.

CROSS-EXAMINATION,

By Mr. Todd.

Q. Professor, when the floats were first put in the drainage canal, you stated they were lost or taken out?

A. During the succeeding night, yes.

Q. How do you know they were taken out?

A. I know because I was told by Mr. Mersereau who was in immediate charge of that part, that when he was going forward the next morning, there were some of the floats that he had allowed to run all night—he found them in the possession of I think someone on the bank of the canal who had pulled them out and who was there with them at the time.

2916 Q. Those were floats that were lost in the canal proper?

A. Those were floats which were interrupted. No sir, I would not say they were lost.

Q. I mean interrupted.

A. Yes sir.

Q. You recovered those, did you?

A. Yes sir.

Q. The reason I ask you this is, there was no interference on the part of the Sanitary District, in these experiments that you could find, was there?

A. No sir.

Q. Did you make any investigation as to the volume of water coming down the Illinois River at the time this experiment was made?

A. No sir.

Q. Are you acquainted with the conditions that obtain in the Illinois River under normal conditions?

A. To an extent; simply from observation of the fact at different times when I have seen the river under different conditions of flow.

Q. How do the conditions that would be denominated normal compare with the conditions that existed at the time that this experiment, or these experiments were made?

A. At the time these experiments were made the river was much higher than the average condition of the river. In fact,
it was overflowing the low lands. The necessary accom-
2917 paniment of that fact is that the current was swifter, and
there was drift-wood running.

Q. Now, professor—

A. If that's all you wish, I have nothing more to say, sir.

Q. Do you know how high the river was above the normal flow at the time this experiment was made?

A. I could tell you that sir, if you could tell me what the height of it is at normal flow. I hardly know what to place as that condition.

Q. You are not acquainted then with the Illinois River sufficiently to know what the normal flow of the river would be in the absence of flood waters?

A. Would that mean the total flow for a year for instance, divided by the number of days in the year?

Q. No, the ordinary stages of the river?

A. I think through all the lower portion of the river that is entirely controlled by the locks and dams.

Q. Then an evidence of the conditions of the water would obtain in ascertaining the height of water that was above the four different dams in the Illinois River, wouldn't it?

A. I suppose so, yes sir.

Q. How high was the water above the crest of the dam at Henry at the time this experiment was made?

A. That I don't know; I have been unable to get those
2918 records.

Q. And at Copperas creek?

A. I don't know that.

Q. And La Grange?

A. I don't know.

Q. And at Kampsville?

A. I don't know.

Q. Did you have any opinion at that time in regard to the height of the water above the crest of the dams at those four places?

A. I think that can readily be deduced when the observers who passed those points testify, because they had orders to read such gauges; and if we can tell the gauge readings at ordinary stages at those points, we can readily get those facts. I don't know them.

Q. If the water was six to ten feet above the crest of the dams at those four different places at the time you made the experiment, that would indicate, wouldn't it, that there were flood waters in the Illinois River?

A. Yes sir.

Q. And is it not a fact that at the time this experiment was made there was a great amount of flood water in the Illinois River?

A. Yes sir.

Q. The river had overflowed its banks from LaSalle, practically to Grafton, hadn't it?

2919 A. I couldn't say certainly; I think so, through the larger part of that distance, certainly. At Peoria, for instance, the river was practicaly confined to its channel, to the old channel because the banks are high in that vicinity.

Q. That was not true at Peoria, was it, doctor?

A. Well, it was a trifle wider on the Peoria side.

Q. Which is below Peoria, just before you get to Peoria?

A. Between Peoria and Pekin it had widened a trifle.

Q No; just immediately below Peoria, wasn't the water, or didn't the water overflow its banks, right bank, to an extent of several miles?

A. I don't know how far.

Q. Did you go down from Peoria to Pekin?

A. Yes sir.

Q. Do you remember the sanitary district that was mapped out just below Peoria that the dikes had broken away and the waters had extended over that vast territory?

A. I don't know about the sanitary district you speak of, but the lands below Peoria, between Peoria and Pekin, were overflowed for wide distances. I don't know the distance, but a mile or two perhaps.

Q. At the time you made these observations, the waters in the Illinois river were what you call high, were they not?

A. Yes sir.

2920 Q. Do you know how long that condition obtains in the Illinois River; that stage of water?

A. No sir, it is of variable quantity, and of course a variable length of time.

Q. Your experiments then were based upon conditions most favorable to a swift current?

A. I wouldn't say most favorable.

Q. What conditions could you define as being superior to the conditions that you found at that point at that time?

A. A condition, or actual stage of water as indicated by gauge readings, where the water is rising rather than falling, as it was when our observations were taken. That is to say, it is a well known fact that when rivers are rising the discharge is greater and the velocities are greater at the same elevation of the river, or at the same flood stage, than they are when that same stage is reached on the falling river. Our observations were all of them occurring at a time when the river had fallen; it had passed its crest, or highest water had occurred shortly before the observations were undertaken, and so as a general principle, I can say that the length of time occupied and recorded here is probably greater than it would have been if the observations could have been made when the river was at the same stage, but still rising.

Q. What was the height of the river from which you estimated the fall, at the time you made the observations? 2921

A. The fall was not estimated.

Q. You said it was a falling river?

A. Yes, I say that for the reason that the gauge readings at Peoria for instance, or at any other of the places which I have records of, indicated that the crest of the flood passed before the observations were made; that is to say, at Peoria, when we began on the afternoon of the 14th.

Q. Of what month?

A. March, 1903.

Q. What was the gauge reading on the 14th?

A. The gauge reading was 19.1 feet. Now on the 12th the gauge reading was 19.4 and there had been a rise, a continuous rise from the 7th up to the 12th, and I felt confident that if the floats had passed Peoria for instance, anywhere between the 7th and the 12th, instead of on the 14th or later, the velocities would have been found to have been greater, and following down these charts, the charts indicate more or less all the way down the river that if maximum velocities are desired, they could have been obtained a few days before the observations were taken, with almost a certainity of securing greater velocities than were observed during these observations.

Q. How much lower was the river at the time you made these observations than the maximum height?

A. Well, I can only give an average reply to that. Perhaps I could give it for specific cases and specific places. 2922 It is variable all along, it would probably range from practically nothing to a foot less than the maximum.

Q. Then this experiment that you conducted was made during a stage of the river which ran from nothing to one foot below its maximum flood?

A. During this month?

Q. Yes, during this month?

A. Yes sir.

Q. The time calculated was calculated upon the channel flow?

A. As near as I could get it. It was calculated, as I said this morning, on the actual time covered by the floats as observed.

Q. What was the proportion of water in the channel, to the water in the Illinois River outside of the channel?

A. I don't know.

Q. You made no calculation upon that?

A. No sir.

Q. Have you any judgment upon it?

A. Only the roughest. It is a very variable quantity. In places the water was entirely confined to the channel and in other places it was spread for probably miles wide, with a very slow flow. I should hesitate to give a guess and it would be nothing but a guess, at the proportion in the channel and 2923 the proportion at the side. If I were obliged to, I might guess it 90 per cent of it in the section between the natural banks of the river on an average.

Q. That is an average of 90 per cent is in the channel?

A. I think that would be fair.

Q. How did the water along the overflowed banks compare in velocity of current with that in the channel?

A. Very much slower.

Q. Can you give any figures that would convey an idea more clearly than the adjectives which you used to express it?

A. No sir, I cannot.

Q. Was the water in the basins beyond the banks of the river, or rather did the water in the basins of the overflowed land have any perceptible current?

A. As far as I saw it, it was barely perceptible.

Q. It was practically in a stagnant, slow condition, was it not?

A. As far as I saw it.

Q. And how much land was overflowed?

A. I don't know, sir.

Q. By the river, that you observed?

A. I only observed it at this time between Peoria and Pekin, and then only causually. Apparently the width varied from nothing at Peoria and nothing at Pekin where the bluffs extend to the river, to somewhere between a mile and two 2924 miles between the two cities, and the depth changed, say from a few inches to perhaps a few feet, as indicated by grass still rising through the water, and bushes in most places, and things like that.

Q. Did you observe the width of the channel at Lake Peoria?

A. Only as I saw it from the Peoria Highway bridge.

Q. Could you see the width of the stream at that point?

A. I could see that it was very wide.

Q. Approximately how wide?

A. Well, I would hesitate to give an estimate unless I had seen it across the stream, which I did not.

Q. From your observations in this experiment, are you able to tell what the velocity of the current would be if the Illinois River was contained within its banks?

A. No sir.

Q. The condition that you found in the Illinois river, does that condition obtain the year round?

A. No sir.

Q. What period of the year does that condition obtain in the Illinois River?

A. I don't know.

Q. Have you any idea about it?

A. Only the most vague.

Q. Does it obtain for a period of six weeks during the 2925 year?

A. I don't suppose it will average that much. I speak without definite knowledge.

Q. Would it obtain for three weeks, professor?

A. I have no idea, when you get to that point.

Q. Then you wouldn't put it above six weeks, would you?

A. Not as a guess, no sir.

Q. Then the experiments that you made would apply to the Illinois River for a period not to exceed six weeks throughout the year, would it?

A. I presume so.

Q. Do you know or have you any information in regard to the volume of water that you found in the Illinois River at the time you made the experiments, as compared with the volume of water that would be in the Illinois River, if the Illinois River was contained within its banks?

A. I have been unable to get such facts.

Q. That information is obtainable, is it not?

A. I don't think so.

Q. Is it beyond the scope of engineers to make those calculations?

A. No sir, but I think they have never been made.

Q. That's what I mean. It is possible to find that out, isn't it?

A. It is.

Q. By engineering skill?

A. Yes sir.

2926 Q. You mean when you say it has never been done, that you don't know of it having been done?

A. I don't know of it being done, nor have I been able to find that it has, after inquiry.

Q. Now, as to the gauge readings that you collected along the Illinois River; what are those gauge readings based upon; what is the data from which they are taken?

A. It is wholly an arbitrary thing.

Q. Beginning at what?

A. At no definite point for the zero reading, unless or except in certain instances—it is the endeavor of course, at gauges at locks and dams, to put the zero of the gauge below the lock, at the level of the mitre sill, or of the gauge above the lock at the elevation of the upper gate or top of the upper gates, but there is no regular and definite place to put the zero of gauges universally used.

Q. Take it at Peoria; you read I believe, the gauge reading there as 19.1 feet?

A. 19.1 feet above, yes sir.

Q. What does that mean?

A. That means that the record that day was 19.1 feet vertically above the zero of that particular gauge.

Q. What does the zero signify at Peoria?

A. Nothing in particular. The way to interpret that 2927 reading would probably be by stating that the low water reading for Peoria is 2.6 on the same gauge, and that at high water the reading (I suppose from that—I can explain) the highest water previously of record is 21.9 feet.

Q. When was that?

A. I don't know, sir.

Q. And the 19.1 feet was the difference between the low water gauge as you gave it on the 19th, showing the height of water above the low water reading?

A. We would subtract 2.6 from 19.1 to get the height above the low water reading, yes.

Q. Is there any way of ascertaining the velocity of the current if the height of the gauge reading is reduced instead of 19 or 18 feet above the zero, suppose it was 10 feet above zero?

A. Is there a way of computing the velocity of that current?

Q. Yes, in your experiments?

A. It would be exceedingly crude and liable to a very considerable percentage of inaccuracy. There are ways of attempting to arrive at such a thing, but it is very likely to be wide of the facts.

Q. Then your experiment only serves to prove the velocity of the current at a time and under conditions that existed in the Illinois River at the time that the experiment was made?

A. Yes sir.

2928 Q. It doesn't show what the velocity of the current would be at other stages of the year, when the water in the Illinois River is considerably lower than it was at the time that you made the experiment, does it?

A. No sir, it would not furnish proof of such velocity at any other stage.

Q. From Grafton to the Chain of Rocks, at the time that you made this experiment, what was the stage of the water in the Mississippi River?

A. Do you mean the gauge reading, or about?

Q. The gauge reading?

A. The gauge at Grafton read 16 feet; the gauge at St. Louis 23.4.

Q. What does that mean, professor?

A. That means that the water in the river at those respective places was at the height above the zero point of the gauges which is given.

Q. Now what does the zero point mean in the Mississippi River?

A. That can best be indicated by giving the lowest water reading at Grafton on the same gauge, which is minus .3 feet, with the corresponding high water reading.

Q. Right there, professor. Minus .3 feet; does that mean the bottom of the river?

2929 A. No sir, that means the surface of the river at the lowest water that has been observed there.

Q. And do you know how far below that surface was the bottom of the river at that point?

A. I don't know at the present moment. That would be told from the depth of the water of course.

Q. We had these once before and I was trying to get it straightened out. That is the reason I am asking these questions.

Q. Now if the stage of the river that you have read at Grafton at the time that this experiment was made—it was how much?

A. 16 feet.

Q. If it was 16 feet, was that a normal or an abnormal flow in the Mississippi River?

A. That was certainly greater than the average flow.

Q. It was what is known as high water?

A. Yes sir.

Q. Coming down the Mississippi to the point—may I have that chart you exhibited this morning—coming down from the mouth of the Missouri River, down to the Mississippi River, to where a sand-bar appears in the Mississippi River, is that sand-bar under water or above water?

A. When the observations were made?

Q. When the observations were made?

A. It is, I suppose, entirely under water, with bushes and trees growing upon it, of course above the water surface.

2930 Q. Do the bushes and trees grow entirely over the sand-bar or do they only grow on a part of the sand-bar?

A. As far as I know they cover it. I won't be positive of the covering of the whole of it.

Q. Does the water of the Mississippi flow over that sand-bar the greater part of the year, do you know?

A. I think not.

Q. Does the water of the Mississippi pass to the left of that sand-bar during the entire year?

A. I don't know of my own knowledge. I understand that at low water stages, very little, if any, passes to the left of the sand-bar.

Q. Do you know what proportion of the year the Mississippi is at low water stage?

A. It varies with the year. For instance last year there was no what might be called low water stage, and the year before there was a great number of weeks when it was.

Q. Is there any channel to the left of the sand-bar that we are talking about, in the Mississippi River?

A. Yes sir.

Q. Do you know what the depth of that channel is, professor?

A. No sir.

Q. Have you any idea as to its depth?

A. Not at the present time. I believe that the upper end
2931 of that channel has been closed by a jetty, which would
cause it to fill and would obstruct the low water flow through it. These depths we see here were the depths at the date this map was made and before such jetty was put in.

Q. Doesn't the sand-bar project considerably west of the line of vegetation?

A. I don't think so very much.

Q. The three islands south of the sand-bar are about how large, Professor?

A. They were submerged when my observations were taken, and I have not been in that vicinity during low water recently so that I could answer at all. There are changes since that map was made, to a greater or less extent, how much I don't know, in the size of the islands.

Q. East of the intake, do you know whether the island forms the bank of the river or whether there is a channel around that island in the river on the Illinois shore?

A. I believe there is a channel between that island and the Illinois shore, through which the waters, in high water stages, make their way. I understand there is practically no flow there during low water stages.

Q. Professor, after you left Joliet some of the floats were lost again, were they not?

A. From Joliet to Grafton?

Q. Below Joliet?

2932 A. Yes, there were.

Q. How did they become lost?

A. Mostly from flowing into the woods from the side channels, which are full at high water, and getting away.

Q. What did that indicate as to the current?

A. It indicated that the waters of the river separated wherever there was an opportunity to, and the current is more or less dissipated.

Q. And the water went over and submerged the lands?

A. Yes sir.

Q. Do you know whether the men operating under you kept the velocity or made a memorandum of the velocity of these floats through what is known as Lake Joliet?

A. They did.

Q. What was the velocity?

A. Well, they made the velocity experiments in this way; they noted the time of passage through but not the velocity as it may be expressed in feet per second, for instance.

Q. Have you the data showing the time that these floats entered Lake Joliet and the time that they emerged from Lake Joliet?

A. Not in that way. I do not know; and from the records I have, I cannot identify the upper end of Lake Joliet. The time from Rome to Peoria, if that is at all indicative—

2933 Q. No, Lake Joliet is immediately below Joliet.

A. No, I have not; I cannot give that. I can give the time from Bear Trap Dam, in the aggregate, to Joliet.

Q. Well, from Joliet, where is the next point?

A. Morris is the next. We will locate a point 24 miles.

Q. They did not make any data in regard to this point of which you speak?

A. They undoubtedly did, and I imagine the engineer who was in local charge, can give you those facts.

Q. Did they make any data of Lake Peoria from the time that the floats entered Lake Peoria?

A. I think that can be arrived at in the same way. All I could give was the time from Rome to the Peoria bridge.

RE-DIRECT-EXAMINATION BY MR. JEFFRIES.

Q. Professor, I would like to have you take this chart or map and explain what it is?

A. This is simply a tracing I had made to show the point at, or figures of time of the flow from really the Chicago River to the St. Louis waterworks intake, embodying graphically what was given in the figures this morning. That is to say, the towns are given along the river and the distances of those towns from Lockport, successively all the way down, and the aggregate time at which each of those towns was reached. Say for in-
2934 stance, here we have Ŭtica, a distance of 62 miles from Lockport. The aggregate time of flow from Lockport to Utica being 29 hours and 51 minutes, and so for all the rest, and the time is given in the notes here of passage through the drainage canal.

Q. This was prepared by yourself, was it?

A. Yes sir.

Q. Upon the figures made by the men you had to make these observations?

A. Yes sir.

Q. As to the velocity of the Illinois River during the month of March, 1903?

A. Yes sir, and the figures, for instance, were taken from tables furnished me by the different United States engineering offices. I don't know how correct they are.

MR. JEFFRIES: Mr. Commissioner, I would like to have you mark that paper Complainant's Exhibit No. 40. I offer it in evidence.

Said map marked Complainant's Exhibit No. 40.

2935 RE-CROSS-EXAMINATION BY JUDGE JOHNS.

Q. The distances marked on that chart are the distances by river?

A. As well as I could get at them, yes sir.

MR. TODD: And this is at the stage of water you have testified to in your testimony?

A. The times given there correspond with the stage of water existing during the observations, yes sir.

MR. TODD: I object to the map for the same reason that I objected to the data from which the copy was compiled, namely, that it was based upon hearsay and not the personal investigations of the witness.

RE-DIRECT-EXAMINATION BY MR. JEFFRIES.

Q. I will ask you, professor, if it is not a fact if you know, that the water would spread out over a considerable portion of low land near Peoria, even in low water of the Illinois River?

A. I have never been there at such a time, so I don't know.

Q. Professor, I will ask you if you ascertained the water stages of the Illinois River from Chicago to St. Louis or various points along the river and the canal?

A. Those were read at the time the parties passed such
2936 gauges but only at such times as they were passing them.

Q. Did you make any effort to obtain the water gauges of the canal and Desplaines river?

A. I made a very extended effort to get the gauge readings of the upper Illinois and the Desplaines river, all above Peoria, of at least a dozen or fifteen different sources of information that I thought might give them to me and found that the Chicago Drainage Canal controls all such readings. I then wrote to Chief Engineer, Mr. Randolph and he replied very courteously that after consultation with the legal advisers, he must refuse them.

Q. When was that that you made this effort to get these readings?

A. I have been continuously making this attempt since these observations were begun, and have in every case asked for such readings during the month of March, 1903.

Q. Then it was during the month of March, 1903?

A. I made the request to cover the month of March, 1903, and have been up to last week trying to get them.

RE-CROSS-EXAMINATION BY MR. TODD.

Q. Did you get a letter from Mr. Randolph in regard to the gauge readings?

A. Yes sir.

2937 Q. Have you got that letter with you?

A. I have.

Q. Will you produce it?

A. Shall I read it?

MR. TODD: I would like to have it read into the record.

GENERAL CROW: Let me see it before you read it into the record. We may not want it read into the record.

(Witness hands letter to General Crow.)

GENERAL CROW: There is no objection to reading that letter.

MR. TODD: Read it into the record.

THE WITNESS: (Reading) "Chicago, April 27, 1903, J. L. Van Orum, Esq., Professor of Civil Engineering, Washington University, St. Louis. Dear Sir. I have yours of the 25th instant, *in re* gauge readings in the Desplaines and Illinois Rivers. I hope that in what I am about to say, you will acquit me of any discourteous intention, and believe me, when I assure you that in time of peace, that everything I could do to serve you would be done. After advising with our attorney I must decline to furnish any facts bearing upon the St. Louis situation which would aid said city in preparing its case against the district. All physical facts possessed by us which have any bearing upon the questions at issue, will be presented when the State of Illinois and the Sanitary District present its case. Yours very truly, Isham Randolph, Chief Engineer."

2938 MR. TODD: You said, Professor, that all the gauge readings you found were under the control of the Sanitary District or something to that effect, did you not?

A. Yes, every source of possible information which I approached, either referred me to someone else, who in turn referred me, or referrrd me directly, to the Sanitary District as controlling those gauge readings and taking them.

Q. And to what points did you have reference?

A. I asked particularly for gauge readings at or near Lockport or Peoria, preferably Lockport, and at or in the vicinity of Ottawa and LaSalle, so that I could divide the river, you see, into approximately equal distances all the way down from the upper end to the lower.

Q. And the answer that you got was the authority for the conclusion that you gave, that all gauge readings were under the control—or putting it the way you did—of the Sanitary District?

A. Yes sir, it was the inference from the replies that I received.

Q. Do you know whether any of the parties to whom you spoke, had any authority to speak for the Sanitary District?

A. I know definitely of only one such case. That was the man who appeared to be in control of the Bear Trap Dam at Lockport.

2939 Q. I mean outside of the District's property.

A. No sir, I do not. No employe as far as I know, of the Drainage Canal told me that such readings were taken by the drainage canal people. There was, for instance the City Engineer of Joliet, who told me that if the readings were taken at Joliet by any one, it was done by the drainage canal people, and other similar replies were made.

Q. Was the same said at Peoria?

A. I have the Peoria readings; I didn't need them.

Q. And at other points below Joliet?

A. Yes, similar replies were sent in those cases.

RE-DIRECT-EXAMINATION BY MR. JEFFRIES.

Q. Professor, identify that chart and state what it is?

A. That is a graphic representation of the gauge reading of the Mississippi River at Keokuk and Grafton, and at St. Louis during the month of March, 1903, and at Hermann, Missouri, for the Missouri River for the same time.

Q. Did you prepare that?

A. Yes sir.

Q. From what?

A. I prepared that from figures furnished to me in most cases by the Weather Bureau, and in one case by the figures furnished directly by the gauge reader.

2940 Q. Which case was it?

A. That at Keokuk.

Q. That was directly by the gauge reader?

A. Yes sir.

MR. JEFFRIES: Now we offer this chart as complainant's Exhibit No. 41 and ask to have it marked by the Commissioner.

Chart marked by the Commissioner "Complainant's Exhibit 41, Frank S. Bright, Commissioner."

2941 JUDGE JOHNS: We object to the chart as not competent evidence and not prepared from any data which has been verified and known to be correct.

MR. JEFFRIES: I will ask you to identify this chart and state what it is?

A. This is a chart prepared by me showing the gauge readings in the Illinois river during the month of March, 1903, at Peoria, Beardstown and Grafton, Illinois. This was prepared by a table furnished by the Weather Bureau also.

Q. What do the figures on the lower margin of the chart or map represent?

A. The day of the month and the figures at the side in ink represent the gauge readings.

Q. In feet?

A. In feet, yes sir.

MR. JEFFRIES: I will offer that chart in evidence and ask to have it marked Complainant's Exhibit No. 42.

MR. TODD: I object to it for the same reason as was given in the objection to Exhibit No. 41.

Chart marked by the Commissioner "Complainant's Exhibit No. 42, Frank S. Bright, Commissioner."

2942 MR. JEFFRIES: You have the original data from which that chart was made, in your possession, have you?

A. Yes sir.

Q. Professor, state whether or not the wind, taking it as it blew, on the day that you observed, and the observation of the velocity of the current of the Mississippi made from Grafton to the intake at the Chain of Rocks, would be sufficient to throw the floats on the west side of the Intake and explain fully, whether or not?

A. The wind as it existed during these observations, in its effect upon the float, was not sufficient to drive it or carry it to the westward of the intake, supposing of course that without wind it would have gone to the eastward of the intake. I say it is very evidently the case in the first place (and it must be said that the wind does have an effect upon the float) because it reaches the exposed portion of the float; and the amount of that effect is a matter for computation, depending upon the circumstances existing.

Q. Mathematical computation?

A. Yes. Do you wish me to go into the details of this computation?

Q. Yes, I think you ought to explain the system.

A. Authorities, whose authority is entirely reliable for deriving the principle, state that the effect of any fluid upon 2943 a body, varies in its effect upon that body as the area of exposed surface, and particularly as to the square of the velocity of the moving fluid, and also particularly as to the density of the fluid. Now I consider in this case we have a situation like this: the wind affecting the upper portion and opposing that effect of the wind the resistance of the fluid in which the lower portion of the float is suspended; and there will be a sidewise movement until the resistance offered by the water, equals the pressure exerted by the wind.

Now the average velocity of the wind at the water surface, from the time the floats were 50 feet from the Illinois shore, to the time they passed the intake tower, is estimated at eight miles an hour. Of course this estimate was made and recorded in my field notes before any such computation was made. The area of surface exposed to the wind, is the area of that buoy part of the float above the rim, and of the flag and its wire stand extending above it. The area of the vertical projection of that cone in which the flag rests—the part above the horizontal rim, is 16 square inches, and the best and most authoritative experiments on the effect of wind upon a conical surface, indicate that the equivalent area of a plain surface, which would offer equal resistance, is 38/100 to the projection of the conical surface, or 38/100 of the sixteen square inches which I have just mentioned.

38/100 of these sixteen square inches gives us practically six square inches, as the equivalent plain area of surface 2944 exposed to the wind in the conical portion of the buoy part, and to that the area of the flag wire and of the flag itself as it is wrapped around with wire, would add about one square inch, or make seven square inches in all as the equivalent area exposed to the wind pressure. Now if that vane portion of the float, floated with one of those vanes at right angles to the current, the area would be 144 square inches, but I have considered the worst condition, where one of those vanes is at an angle of 45 degrees, with the direction of the wind, offering the least resistance, and in that case the area of the vanes exposed to the current is 122 square inches. The chain which is also exposed to the current would add eight square inches, as near as may be, to these 122 square inches, or giving a total of 130 square inches surface exposing itself to the resistance of the water. Reynault, Ganot and other physicists, who have measured and observed very accurately the density of air as compared to that of water, state that at zero degrees centigrade, or just above, for water, so that it isn't freezing, and at a barometer pressure of 660 millimeters, water is 773 times as dense as air. That is to say a cubic foot of water will weigh 773 times as much in a vacuum as a cubic foot of air. Now to arrive at the definite effect of the wind, and to determine how much this wind would drive or influence the float in a certain direction, we can say that the weight of 2945 water, 773, as I have just given, times that of air, of exposed surface, 130 square inches as just given, times the velocity of movement, which is at present unknown, and which we wish to find, is equal to a weight of the equivalent unit of air, or unity, times the exposed area of the surface of seven square inches, times square of the velocity of the wind, or 8 miles an hour squared, which is 64. Seeking for the unknown velocity of water, which would offer an equivalent resistance, we find that this velocity is 0.066 miles per hour. Now as I stated this afternoon, in trying to arrive at the effect of the wind, I found that the average direction of the wind with reference to the direction of the current was such that the effect of the wind was .6 what the effect of the wind would have been at the same velocity if it had blown constantly, directly at right angles to the direction of flow in the river. So, multiplying this by the .6, we get, wouldn't we, .04 miles per hour as the equivalent velocity of the water in the direction which would carry the float sidewise at right angles to the direction of the stream. Now how long was this influence exerted. I have taken it as being exerted all the way down the river from a point opposite the Missouri River point when the floats were about 50 feet from the Illinois shore, to the time they passed the intake, which was practically 100 minutes, so multiplying this .04 miles per hour by the 100 minutes, and dividing by 60; multiply this result by 5280, which is the number of feet in a mile, to reduce the effect of the wind to feet, I found that on this basis the effect of the wind was to move the floats toward the Missouri River shore about 350 feet. That is to say, in all probability if there had been no wind whatever that day the float would have passed about 350 feet nearer the intake than it did, about 350 feet further from the Missouri shore than it did actually pass. 2946

Q. You testified, I believe, this morning, it passed about 700 feet?

A. About 700 feet from the Missouri shore, yes.

Q. And that the intake was about 1500 feet from the Missouri shore?

A. Yes.

Q. Then, from your calculation the wind was not sufficient to throw the floats on the Missouri side, and between the Intake and the Missouri shore?

A. No sir.

Q. Then, if there had been no wind, according to your calculations, where would the floats have gone?

A. This four foot float which is exhibited, would probably have passed about 450 feet to the westward of the Intake instead of 800 as it did.

Q. Now the system that you have used in these calculations is one that is generally adopted by civil engineers in estimating these matters, is it not? 2947

A. It is the most authoritative method that there is; the most reliable one, and practically the only one I know of, of any reliability, the only one that would be used.

Q. Examine this, Professor, and state what it is?

A. This is the float we called White No. 5, on which I wrote my name, at the time it was used in the Mississippi River, as being the one passing (without being touched in its course from above Alton to the St. Louis waterworks intake) as I have stated, about 800 feet westward of the intake before it was taken out.

Q. Now this is one of the floats that was used in this experiment, was it, concerning the velocity of the water from Chicago to St. Louis?

A. Yes sir, this is the identical one which was used from Grafton to St. Louis, and the others were entirely similar, the only difference being in the length of the chain.

MR. JEFFRIES: We offer this float in evidence as complainant's Exhibit 43.

Float marked by the Commissioner "Complainant's Exhibit 43. Frank S. Bright, Commissioner."

2948 RE-CROSS-EXAMINATION BY MR. TODD.

Q. At the time, Professor, that these calculations were made, what was the condition of the waves?

A. I don't apprehend the question I am afraid. The calculation was made after the return from the observations.

Q. I mean the data from which these calculations were made; what was the character of the water—was it smooth as a looking-glass?

A. No sir.

Q. Or was it wavy?

A. It was wavy.

Q. How high were the waves?

A. The force of the wind and consequently the height of the waves was reduced toward evening. It was the highest that day during the middle of the day and the waves then were such that at times we could see probably half way from the extreme rim of the buoy to the lower point of the buoy part of the float, and at times the buoy was submerged to a point about half way from that horizontal rim to the upper point of the—

Q. At any time during the—

A. There was an apparent movement of the water so as part of the time to expose the buoy down to about here (indicating on exhibit 43.)

Q. Probably about like that (indicating)?

2949 A. No, a little bit under the surface of the water.

Q. Did you make any calculations in the problem that you have given us, of the time that that surface of the buoy—the under surface, was exposed to the wind?

A. No sir, I assumed that inasmuch as a part of the time some of the lower portion was exposed to the wind, and during other protions of the time not even the full portion above that rim was exposed to the wind that the fluctuations balanced each other and that the average condition could be considered, where all of that portion below the horizontal rim was entirely exposed to the water, and the portion above the horizontal rim entirely exposed to the wind—during all the time—it was an average.

Q. When the buoy would go over the crest of a wave and turn up, it would present a perpendicular surface for the wind to strike, would it not?

A. Conditions were not enough to turn it perceptibly to the wind. The waves were very short and choppy and really the up and down effect was the only effect noticeable in the float. There was no tipping effect—the waves were small and it was so that it really bobbed up and down without tipping appreciably.

Q. So that it didn't take that motion?

A. Not to any appreciable extent.

Q. Were you able to calculate, or were you able to determine whether the under surface of the buoy was inclined so as to give a perpendicular surface for the wind to strike at 2950 any time or any number of times?

A. I didn't attempt to calculate that sir, because I know from watching the float that such a condition did not exist.

Q. Did you make a calculation based upon the effect of the wind when it bobbed up out of the water and struck the lower surface as well as the upper surface?

A. No, that condition of things which existed was generalized in this way, as though the calculation was made upon the assumption that the average condition and the fair condition on which to make this calculation is that everything below that horizontal rim is not exposed to the wind at all, but only to the water and everything above that horizontal rim is exposed to the wind only, and while that condition did not exist much of the time, exactly, still the position of the float and of the buoy part of it—particularly with reference to the water surface, was such that that was an average condition—that condition on which the computation was made, is the average condition that existed.

Q. Well, assuming that the wind struck the lower part of the buoy as often as the buoy was up out of the water, what do the authorities hold as to the effect of the wind striking an incline towards the water, such as is indicated upon this buoy?

A. I know of no investigations of that.

2951 GENERAL CROW: That condition did not obtain either, did it, in this experiment?

A. It obtained occasionally. That is to say, the rim was above the water surface sometimes, so that the wind would reach the lower cone, and I suppose the attorney's question refers more or less to the effect of imprisonment of the wind between the water surface and the surface of the cone; but that condition was only momentary and the situation varied from that as I have said, to the condition where the buoy was not only buried to the horizontal rim, but buried enough to, as far as we can tell, balance the effect.

MR. TODD: How did you calculate the velocity of the wind?

A. Simply from being obliged for a great many years to arive at that from observation only.

Q. Did you have any instrument?

A. No sir.

Q. Did you ever use any instruments in the calculation of the velocity of the wind?

A. Yes sir.

Q. Was it from instrument observations that you say you were compelled to make the velocity of winds that enable you to form an opinion as to the velocity of this wind?

A. That helped, of course, and I have also, where I was obliged to make such estimates, as often as I could, compared them to nearby readings of wind velocities, so as to per-
2952 fect myself as far as I could, in this kind of thing.

Q. Was this a steady gale of eight miles an hour, or did it come in gusts?

A. Well, as far as I know, all winds come in gusts more or less. As "steady" is generally used with reference to winds, however, this might be considered as a steady wind, and yet, of course—

Q. And then the velocity of the wind is merely a guess?

A. It is an estimate.

RE-DIRECT EXAMINATION, by General Crow.

Q. It is not a guess in any sense; it is simply the opinion of an expert, isn't it, based on wide experience in determining the velocity of wind without instruments?

A. I think that may be said.

Q. You have had a good deal of experience of that kind, haven't you?

A. Yes sir.

Q. Go back to the proposition that he diverted from when I started to examine you. The top of that float; the conical portion of the top you started to say, was submerged equally as much under the water as the lower conical portion was lifted above it by the action of the waves?

2953 A. Yes sir.

Q. And thus you say you thought it would be fair enough to consider that in the calculations?

A. Yes, there was that consecutive condition, one following the other.

Q. The cone itself—the float was built for the purpose of keeping it from tilting, wasn't it?

A. Yes sir.

Q. So as to make it stay erect.

A. Those dimensions given it were determined for that purpose.

Q. Now, the action of waves and the action of wind were both calculated upon in the building of that float?

A. Yes sir.

Q. And it was built under your direction?

A. Yes sir.

Q. And is such a float as is built and operated by civil engineers when they desire to test the flow of a stream?

A. Very frequently, yes sir.

MR. TODD: Just one question, Professor. In your calculations, did you calculate the effect of the wind on the water itself in diverting the current?

A. No sir.

Q. Does the wind have any effect upon the current in 2954 diverting it?

A. It does at the surface.

Q. How far below the surface does that extend?

A. It depends upon the velocity of the wind. There is probably no effect whatever—no appreciable effect—no effect that could be expressed in figures comparable to this 350 feet for instance.

GENERAL CROW: For measurement, you mean?

A. That can be measured or definitely stated, at a depth of four feet at which this vane portion was carried.

MR. TODD: In your calculations does the effect extend as far as six inches below the surface?

A. I think it would, yes sir.

Q. And would that effect upon the current six inches below the surface add any effect to the wind as upon the buoy? Do you get my idea?

A. Yes sir. I think it would have a very slight effect indeed in tending to move the buoy sidewise.

Q. Was that taken into consideration in—

A. No sir, it would be an exceedingly small percentage of the total as given.

GENERAL CROW: Would it be appreciable in measurements sufficient to affect the result as to whether it would pass inside of the intake?

A. Oh no; no sir.

2955 RE-CROSS EXAMINATION, by Judge Springer.

Q. Where were you, Professor, when you made these observations—where were you?

A. I was in a steam launch in the vicinity of the floats all the time.

Q. How did you get the measurements as to the relative distances from the shore of these lines?

A. By estimation.

Q. Estimation?

A. Yes sir.

Q. What do you mean by estimation; by your eye you mean?

A. Yes, by eye and experience in that class of work a great many years.

Q. You were on a steam launch; you had a pencil and this map before you and you observed and you marked this line about where you supposed it would be if a tape line were put upon it?

A. Why, that isn't precisely it. I noted in my field note book the distance from shore at certain consecutive points and when I reached my office I plotted that line with reference to these records.

Q. Well, the line is simply the result of the field notes which you made?

A. Yes sir.

2956 Q. Therefore the field notes were your estimates as to what the distance was?

A. Yes.

Q. From shore?

A. Yes sir.

Q. And you based that entirely upon your vision—what you saw?

A. Yes sir.

Q. You had no actual measurements?

A. No actual location or measurements.

Q. Did you make more than one experiment between Alton and the intake as to the velocity of this float?

A. No sir.

Q. You did not?

A. No sir.

Q. Why did you not make another estimate in order to test the correctness of your calculations?

A. Well, because no launch was furnished me and I wasn't asked to take the time for it, sir.

MR. JEFFRIES: It wasn't necessary?

A. I didn't see any necessity for it.

JUDGE JOHNS: Professor, the vertical projection of the white part of this float is how many square inches?

A. Sixteen.

2957 Q. Sixteen square inches. Then the white part of this float offers as a resistance to the wind, sixteen square inches of surface?

A. No, that doesn't follow, because it has—

Q. Well, if the top of the float had been a vertical plane of sheet iron or tin, it would have had an exposure of sixteen square inches, would it not?

A. Yes sir.

Q. Now the wind was blowing in a general direction from the southeast?

A. Yes sir.

Q. That would make the waves moving across the current of the river in a northwesterly direction?

A. Yes.

Q. The force of the waves, whatever it might have been, would be to crowd the float northwesterly?

A. Yes sir.

Q. And therefore towards the Missouri shore?

A. Yes sir. J. L. VAN ORNUM.

2958 C. V. MERSEREAU,

Recalled as a witness in behalf of the complainant, having been first duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. What is your name?

A. C. V. Mersereau.

Q. You have testified in this case before, haven't you?

A. I have.

Q. Are you employed in the water department of the city of St. Louis?

A. I am.

Q. I will ask you if at any time in the past few months you have made any observations of the velocity of the water in the Chicago drainage canal and the Desplaines River?

A. I have.

Q. State when it was and how you made them and under whose direction?

A. It was under the direction of Professor Van Ornum. The observations were begun on March 15th, 1903, and ended on March 26th.

Q. Now then, what waters did you take observations of?

A. Through the drainage canal from the Western Street bridge to the Bear Trap Dam at Lockport. From the bridge at Morris, Illinois, to a point about seven miles above Henry.
2959 From Chillicothe to Peoria.

Q. Now I will ask you what kind of an instrument you used in taking these observations?

A. For part of the work we used floats similar to the one exhibited here.

Q. Complainant's Exhibit 43?

A. Yes sir.

Q. They were furnished you by professor Van Ornum?

A. Yes sir.

Q. Well now, you state part of the time you used this kind of floats—what kind did you use in addition?

A. We used a float that was made of a white pine picket, about one and one-eighth of an inch square, on the bottom of which were nailed two pieces of tin, bent at right angles, so as to resemble those floats.

Q. Well now, you started in in the canal, did you?

A. Yes sir.

Q. Did you take water gauges along the route?

A. I read no water gauges in the drainage canal at all until after I reached Lockport. At Lockport I read both gauges. The gauge in one corner of the basin showing the stage of water in the canal.

Q. Do you know what that was?

A. Yes sir.

2960 Q. What was it?

A. (Witness refers to book).

Q. You are refreshing your memory now from your field notes?

A. From the field notes. It is recorded in the notes. About nine o'clock on March 16th the water gauge of the Bear Trap Dam at Lockport was 4.4 feet. Allow me to change that time. That was at 6:00 a. m. on March 16th, the gauge on the Bear Trap Dam read 4.4 feet.

Q. Above or below?

A. They read it as plus reading, meaning that the water—that the depth of the water going over the Bear Trap Dam was 4.4 feet. The gauge in the corner of the basin read minus 2.3 feet.

Q. Now in these field notes, what did you keep? Just state briefly what was kept in those field notes?

A. Kept the time that the float was dropped into the water and its approximate position also.

Q. Now that was on all the floats that were put in?

A. That was on all the floats that were put in. Also the time that any floats were picked out of the water, and anything that happened to the float, and the time of passing any marked object.

Q. Well now, would you note the time that the float was deposited in the water again after it had been picked out?

2961 A. Yes sir, the time when a float was picked out of the water, the approximate distance behind any other float was taken, and when it was deposited in the water, it was generally deposited opposite a float, and the time noted.

Q. And the number of the float opposite which this float was re-deposited was always noted, was it?

A. Yes sir.

Q. Do you know when you first started your floats?

A. Yes sir.

Q. You may state that.

A. On March 15th, at 10:19 a. m. dropped white float No. 3 off from Western Street bridge, about 95 feet north of the center of the draw pier.

Q. How many floats did you have there?

A. Shall I read the numbers?

Q. Yes, give the numbers of the floats?

A. Mr. Reed dropped green float at the same time, 75 feet south of the center draw pier, so there were two floats.

Q. Two floats?

A. Put in at that time, yes.

Q. Now then, how did they run and where did they lead you to?

A. I followed the floats that day all day long, until approximately six o'clock that night.

2962 Q. Until six o'clock?

A. Yes, do you want the exact time?

Q. Yes, I want the exact time and the distances?

A. At 6:18 p. m. white float No. 3 passed what is known as the Chicago Terminal bridge.

Q. Now, how long had it run?

A. That had run from 10:19 to 6:18, that would be practically nine—

Q. Between 10:19 in the morning to 6:18 in the evening?

A. Yes, that was the last reading that I took that evening. The float continued in the canal all night and ran—it was picked out of the canal by some laborers at a stone quarry at about half-past nine the next morning.

Q. Now then,what did you do with it when you found it, take it back?

A. I took it back, yes sir.

Q. Back where?

A. Back to the bridge where I made the reading at 6:18.

Q. Where you made the reading at 6:18 in the evening?

A. Yes sir.

Q. Well, what did you do then?

A. I dropped it in the water— no, allow me to change that. I put the white float back in the water at the place

that it had been picked out, and followed it on to Lockport that day. It was placed in the water at 11:48 on the
2963 morning of the 16th. It was taken out of the water at 6:31, about 100 feet east of the north gate tower at Lockport.

Q. At Lockport?

A. Yes sir.

Q. Now then, what became of the other float?

A. The other float—

Q. Did you keep time on it?

A. I did for some time, until the white float was running so far ahead of the green float that I couldn't take time on both of them.

Q. On the first night?

A. On the first night.

Q. You kept time on it?

A. I kept time on it.

Q. You did?

A. Yes sir.

Q. Well now, give us the time that that one—

A. Well, I kept time as long as I could on it. I will tell you that. (Referring to book.) At half-past three the green float was approximately 2,000 feet behind the white float, and from that time on I have no definite readings. At the times that I read the white float passing the bridge, it was too dark to have seen the green float more than 1,000 feet up
2964 stream, and so it was useless to take that.

Q. Well now, go right on through with it?

A. Go right on with the white float?

Q. Yes.

A. The white float was picked out at the Lockport dam at 6:31 p. m., and was taken back to the Chicago Terminal bridge and dropped from the bridge at 8:30 p. m. Here is the record. 8:30 p. m., No. 2, white, dropped into the canal from the C. T. Railroad bridge at south side of draw pier and five feet from it.

Q. That is where you went back?

A. Yes sir.

Q. Is that where you went back?

A. Yes sir.

Q. Going over again?

A. Yes sir.

Q. Now then, that was where you were going back over the same route again?

A. Yes sir.

Q. To that float which had been picked out by those quarrymen?

A. Yes sir.

Q. Now then, carry that from there?

2965 A. The next morning I didn't find the float until 11:57, and that was the first reading that I made on it. It was then approximately two miles above the St. Stephen Street bridge. From there I followed the float down to the quarry where I had put it in.

Q. On the day before?

A. The day before. It was picked out at 3:34 in the afternoon opposite the same point that I had taken the time in starting the float the day before.

Q. Well now, go right on.

A. Well, I picked it out at that point, so that completes—

Q. That completes that section?

A. The record as far as the drainage canal is concerned.

Q. Now then, have you got the field notes of the exact time that it took the float to go through the canal?

A. Why, I haven't got it worked out here.

Q. But you have not given it here in your testimony?

A. No, I worked it out and gave it to Professor Van Ornum.

Q. Now then, take the second section; that statement that you gave—

GENERAL CROW: Let him state the time it went in and the time it went out.

A. The time is broken and it had to be computed from the time that I gave.

2966 Q. MR. JEFFRIES: You stated a moment ago that you started in at a certain place, at a certain time?

A. Yes sir.

Q. And that you took readings of the time about six o'clock in the evening?

A. Yes sir.

Q. Then you let the float go on that night?

A. Yes sir.

Q. And it was picked up by some laborers the next morning, before you reached it?

A. Yes sir.

Q. And that you came back after that and ran that space over again?

A. Yes sir.

Q. And computed the time from the time it was put in to the time it was taken out?

A. Yes sir.

Q. Now take the second section; and commence at the time you put the floats in. Now this second section commences where the first section left off, doesn't it?

A. No sir.

Q. There was another man in between you?

A. There was another man in between.

Q. All right.

A. On March 20th, at 8:40 a. m., white float No. 4 passed
2967 under bridge near middle pier at Morris, Illinois.

Q. That is where you started anew on your second section; is that correct?

A. Yes sir.

Q. That is where you started on your second section?

A. Yes sir. Do you want any of the time in or not?

Q. Yes, if you have them, go ahead.

A. Well the readings are in the books, taken on an average of about every three minutes.

Q. Oh well, I don't want that.

A. The floats were run all day.

Q. And taken out in the evening?

A. They were picked up at 4:24, the float passed under the Marseilles wagon bridge—No, I will have to stop a minute there; that is not right.

Q. Just give where they were picked up that evening?

A. Well, there is a break in there on account of the dam. At 3:50 picked up float No. 4 about one-quarter of a mile above the State dam at Marseilles, Illinois.

Q. That was the green float?

A. That was the white float.

Q. The white float?

A. Yes sir. The float was started again at 4:17 and passed over the State dam where the float was lost. That
2968 was about five minutes from there to the bridge. Then the next morning we started again at 7:30 a. m. I will have to change that time. The gauge was read at 7:50 a. m.

Q. What was the gauge then?

A. 98 feet—the gauge above the State dam at Marseilles.

Q. Go ahead.

A. The floats were dropped off from the bridge at Marseilles at 9:05 and 9:09. They were taken out at 11:30 a. m. at the bridge at Ottawa, at the wagon bridge. The gauge on the wagon bridge in Ottawa is 80.6 or 90.6. The first figure was indistinct and we couldn't make out what it was. The zero and the 6 was plain. The float was started again at the wagon bridge at 1:25 p. m. At 5:12 No. 4 float passed the wagon bridge at Utica, Illinois. Picked out float for the night.

Q. At that place?

A. At that place, yes sir. At 6:55 a. m. March 22nd, float passed the wagon bridge at Utica, Illinois. That was starting again the next morning at the point where we left off the night before. At 11:28 passed Peru wagon bridge. Gauge reading on the bridge, 14.75. At 1:38 p. m. passed Spring Valley wagon bridge. Well, the float was taken out of the water at 5:35 that evening—

Q. Where?

A. Opposite the town of Depue.

2969 Q. Now is that as far as you went on that section?

A. No sir, that was that night.

Q. Now the next morning where did you begin and when?

A. At 6:30 the next morning.

Q. Did you deposit it in the same place?

A. We deposited it opposite the same place and at 10:59 the float passed the elevator at Hennepin, and the floats were run the rest of the day until 5:20 that evening when they were picked out opposite the point about seven miles above Henry.

Q. And that was the end of that section?

A. That was the end of that section. I left Mr. Reed to—

Q. What time was it picked out now at Henry, or seven miles above Henry?

A. At 5:20 p. m.

Q. Now then, the parties that took the observations below that point started in from that place?

A. Started in at that point and took it down to Chillicothe.

Q. And that is where you commenced anew again?

A. And that is where I commenced again.

C. V. MERSEREAU.

ADJOURNED until 10:00 a. m. May 6th at City Counselor's office, City Hall, St. Louis.

2970 City Hall, St. Louis, Missouri. Continuation pursuant to adjournment, 10:00 a. m., Wednesday, May 6th, 1903.

Present, the Commissioner and same counsel representing the respective parties.

C. V. MERSEREAU resumed the stand for further direct examination, by Mr. Jeffries, and testified as follows:

Q. Now, we had concluded the second section of the observations that you were testifying about yesterday afternoon, had we not, Mr. Mersereau?

A. Yes, sir.

Q. Now, commence at the third section and give the place of starting, the time and follow that through to the end of the section.

A. On March 21st, we started at the grain elevator at Chillicothe, at 5:56 a. m.

Q. At when?

A. 5:56 a. m. And then all of that day.

Q. When did you reach the end of the section?

A. Reached the end of the section at 6:43 on the 23rd.

2971 Q. Now during that time you hadn't run during the night?

A. No sir, a part of the time I had run a double set of floats.

Q. Well now, when you would remove the floats from the water at night, you would put them back in at the same place the next morning?

A. Yes sir.

Q. That is, at the place where you removed it?

A. Yes sir.

Q. Noting the time of the removal and the time of the re-deposit?

A. Yes sir.

Q. Now, how long did it take for you to get through that section?

A. 29 hours and 59 minutes.

Q. Now take the third section; did you get any of the gauges during that section?

A. That is the third section, sir.

Q. This is the third section—did you get any of the gauges on that third section?

A. No sir, there were no gauges on that section.

Q. Now take the fourth section?

A. I only had the three sections.

Q. You only had the three sections?

A. Yes sir.

2972 Q. Now then, on your third section you started your float where the party above you had left off?

A. No, I started ahead of the party.

Q. You started ahead of him and he came down to where you started?

A. Yes.

Q. Now then, where did you stop—right where another party had started?

A. Yes sir. Yes, on the third section I stopped at Peoria, highway bridge, where Mr. Van Ornum had started a party about two weeks previous.

Q. About two weeks previous?

A. About that—ten days or two weeks, yes sir.

Q. Do you know who it was that he started there?

A. Mr. Gibson and Mr. Brown.

Q. Now you used these same floats that you started with, did you?

A. Not on the third section. On the third section I had none of those floats.

Q. You had some new ones?

A. I had temporary floats that I had made.

Q. You turned all of this information—all of these field notes over to Mr. Van Ornum, did you?

A. Yes sir, the day following my return from Peoria.

2973
CROSS-EXAMINATION,
By Judge Johns.

Q. Where did you commence your work?

A. Sunday, March 15th.

Q. At what place?

A. Western Street bridge.

Q. How far did you personally follow the floats, or superintend the work of following?

A. Why, I followed the floats personally that day and the next day. During the night one of the floats was running through the drainage canal and nobody followed it.

Q. Where did you quit the following day, on the 16th?

A. On the 15th I got down as far as the C. & C. T. bridge. The float ran that night and was picked out the next morning at about the county line, near where the tablet is in the side of the canal. That morning I started that float again at that point and took it down as far as Lockport; got down there late in the evening. I then took it back to the C. & C. T. bridge where I was the night before and dropped it off from the bridge and allowed it to run all night. In the morning I went below it and walked up the canal until I met it, and then followed the float down until it came to the point, where it had been picked out the day before, where I started the other float.

Q. Now did you follow the floats personally any other place?

2974 A. Yes sir. All the records that I have here were made by my following the float.

Q. Well, did you follow floats from Lockport down to Peoria?

A. No, it was divided into three sections from there.

Q. What section did you take up?

A. I took from Morris down to about seven miles above Henry, and then from Chillicothe down to Peoria.

Q. How far is it from Morris to the place where you left off?

A. Well, that would be a matter of guess work. I could tell—

Q. What day did you commence at Morris?

A. I will have to look and see, sir. (Witness refers to notebook). March 20th.

Q. And you followed the floats how many days then, yourself?

A. I followed it March 20th, March 21st, March 22nd and March 23rd. That was between Morris and a point about seven miles above Henry.

Q. How many hours and minutes for that distance?

A. In the neighborhood of 33 hours.

Q. When you stopped running the floats at a certain place, you timed the taking out by the arrival of the first float there?

A. Yes sir.

Q. On each occasion that you took them out?

2975 A. Yes sir.

Q. The time you gave is the time that the first float arrived at the place?

A. Yes sir.

Q. How many floats did you conduct down the river?

A. It varied. In some places I had five; in other places I only had one.

Q. For what reason?

A. It depended upon the width of the river and the wind and state of the water.

Q. Could you not run five when the wind was running high?

A. When the wind was running high it was almost impossible to attend the five.

Q. Would they be blown over onto the banks?

A. No sir, but the trouble was handling the boat and getting around.

Q. Keeping track of so many floats on account of the difficulties with the boat?

A. Yes sir.

Q. When the wind was high you then ran only one float?

A. I always tried to have in two floats, with the exception of one day, and that day the wind was quite high, and I only ran one float.

Q. Where was that?

A. Just below Ottawa down—well say the afternoon of
2976 the day that we were running from Ottawa down to the
next point—Utica I think it was.

Q. Did you put that float in the middle of the river,—in the middle of the current?

A. It was in the middle of the current a part of the time. I would put a float in the river and try to put it where I thought the point of maximum flow was. Whenever that float appeared to be working too much to one side I would go out and drop another float opposite to the first one and then let them both run from there and see which was running the fastest and then take up the one that was lagging behind.

Q. The object being to keep the float traveling as fast as you could discover current to make them travel?

A. Yes sir.

Q. And you were looking for fast time down the river?

A. I was looking for the actual time that it took the float to go.

Q. And the fastest current?

A. Well, I was taking the fastest float.

Q. And if the float began to get slow you put in another one opposite and ran it?

A. Yes sir.

Q. Now in going down the canal did you have a boat?

A. I did not.

2977 Q. You went along the shore?

A. Yes sir.

Q. Did you have any companions or assistants?

A. During the forenoon of the first day Mr. Reed was with me.

Q. Who is Mr. Reed?

A. Mr. Reed, the man who took the second section. There were two of us left St. Louis, and were supposed to work together, but I found that the time that had been allowed me would not allow us to do the work together, so I sent him down to begin at Lockport and go on down until I overtook him.

Q. Now when he started at Lockport, did he take a boat?

A. He did, yes sir.

Q. What—a launch or a row-boat?

A. A small row-boat.

Q. How many oarsmen did he have?

A. He had one oarsman.

Q. Do you know who he was?

A. I think the name is given in the book here; I would not be sure of that.

Q. Have you a name that you think is the name of the person?

A. I will look and see, sir. (Witness refers to book). Yes sir. George Garver.

Q. Where did he live?

2978 A. He lived at Joliet.

Q. Did he go with Mr. Reed any great distance?

A. He went with him to Morris.

Q. Now when you were on the Illinois River, what kind of a boat did you have?

A. I had a row-boat.

Q. How many oarsmen did you have?

A. I had one.

Q. Where did you get him?

A. I had one on part of the work. I couldn't get an oarsman and I did my own rowing at that time. Mr. Reed was in the boat with me.

Q. Now where did you get a boatman?

A. I hired a boatman at Chillicothe.

Q. Who was he?

A. Harry Wilkie.

Q. Did he live at Chillicothe?

A. Yes sir.

Q. How far did he go with you?

A. Down to Peoria.

Q. To Peoria?

A. Yes sir.

Q. Now did you do any work below Peoria yourself?

A. No sir, I had nothing whatever to do with it.

2979 Q. You quit at the Peoria highway bridge?

A. Yes sir, the lower bridge.

Q. The lower bridge?

A. Yes, the one about the middle of the town.

Q. And at a point where some other parties had previously started floats?

A. Yes sir.

Q. About two weeks before?

A. Well, approximately that.

Q. Do you know exactly the day when the party started at Peoria?

A. I do not, but I think it was the same day that I started at Chicago.

Q. At Chicago?

A. Yes sir.

Q. Do you know who that party was that started at Peoria?

A. There were two men, Mr. Gibson and Mr. Brown, from the Water Department, that went up there with Professor Van Ornum.

Q. Well, while you were on it, the Illinois River was quite high I believe?

A. Yes sir.

Q. How many gauges did you read and where were they?

A. In the drainage canal I read two gauges; one was the gauge on the Bear Trap Dam; the other was the gauge in the corner of the basin. I think the next gauge that I got was
2980 the gauge at Morris, on March 20th, at 8:40, the gauge at Morris was 91.25.

Q. Were they the only ones you saw?

A. No sir, the next one that I read was on the same day at the Seneca railroad bridge; the gauge was 95.0.

Q. What does that mean, 95.0 feet?

A. No sir, I think that those gauges are set with reference to the datum plane of the drainage canal and the reading on them decreases as you go down the river.

Q. What do you understand that that reading 91.25, meant?

A. Well, I don't know definitely what it means, but my idea of the matter is that that is 8.75 feet below the datum plane of the Chicago drainage canal. It was the difference between 91.25 and 100, which would be 8.75. Now those gauges I know nothing about definitely.

Q. What kind of a looking thing was this gauge?

A. Most of them were a board painted with figures on them, fastened to the piers of the bridges.

Q. Marked off into feet and tenths of feet?

A. Yes sir.

Q. Well, when you read 91.25, was that the surface of the water upon that board?

A. The surface of the water on the board.

Q. And the exact significance of those figures you do not
2981 understand?

A. No sir.

Q. Did you read any other gauges?

A. Yes sir. At the Seneca wagon bridge the gauge read 95.5.

Q. What kind of a gauge. Was that also a board nailed to the pier?

A. Yes sir.

Q. And that was the reading at the surface of the water?

A. Yes sir.

Q. And you do not understand the significance of that?

A. No sir, more than as I have stated, that I suppose those gauges were set with reference to some definite plane used by the drainage people, and that the zero of those gauges would correspond with that plane, and that the difference in reading would give the fall of the river.

JUDGE SPRINGER: That would be below the level of Lake Michigan, you mean?

A. No, I don't say that. The zero of that plane may be an arbitrary point. These figures are merely for comparison of the readings at the different points.

JUDGE JOHNS: Did you read any other gauge?

A. Yes sir. No— I had the reading of the gauge about a quarter of a mile above the dam at Marseilles; that was given to me by the gauge reader that morning, but I didn't read the gauge myself.

2982 Q. What was the gauge as given to you?

A. 98 feet.

Q. 98 even?

A. 98 even, yes sir.

Q. And the significance of that you don't understand?

A. No sir.

Q. Except as you suppose it is from some arbitrary datum?

A. My instructions were to read the gauges and I read the gauges without going into further details.

Q. At what other place did you read a gauge?

A. At the Ottawa bridge. There the "10" figure on the gauge was indistinct, and it was either 80.6 or 90.6. The zero and 6 were plain, but the third figure I couldn't make out.

Q. And at what other place did you read a gauge?

A. At the LaSalle bridge the reading there was 81 feet.

Q. 81 even?

A. Yes sir.

Q. And at what other place?

A. I think that is the last gauge—No, there must be one more. I will have to hunt through the book to find that. (Witness refers to book). The gauge on the Peru highway bridge was 14.75. Now this gauge appeared to be a gauge set from a different datum, and I took it to be a government gauge.

Q. Was it a board or an iron rod?

2983 A. I would not be sure about that, sir.

Q. Do you understand that to be 14.75 feet above zero of that gauge?

A. Yes sir.

Q. Well, if you read any others, tell me where they were and what the reading was?

A. I think that was the last gauge reading that I have—that is, that I read. I have a gauge reading that was made at Henry by the gauge reader.

Q. Well, you have already given that have you not?

A. No sir.

Q. Well, give me the gauge at those various places, and the date?

A. On March 24th, the gauge readers—well, it was the lock tender at Henry,—gave me the reading of the gauge at 11.8 feet at 7:00 A. M. He gave me the high water of the Thursday or Friday before that, at 13.4 feet.

Q. Now, did you get any other gauge readings at any time?

A. I think not.

Q. What time did you start from Chillicothe and at what point did you start?

A. I started at 5:56 on the morning of March 21st. The float crossed the road line at Chillicothe about 300 feet from the east bank. No. 1 was in the middle of the channel. 2984 The channel was approximately 1,000 feet wide, and at 6:05 that same float passed the grain elevator at the lower end of the town. And that 6:05 is the time that should be used as the party coming down with the other float took his time at that elevator.

Q. When did you arrive at Peoria?

A. Two days later.

Q. How far did you travel the first day?

A. The first day we got down nearly opposite Mossville.

Q. What time did you take the float out at Mossville?

A. At 5:50.

Q. Of the same day that you started from Chillicothe?

A. Yes sir.

Q. Now when did you start the next day?

A. I started at 6:40 A. M.

Q. And when did you arrive at Peoria?

A. 6:43. That only shows in that time about twelve hours, but as an actual fact the float covered a time in there of about nineteen hours. I was anxious to get through that day— I would put my floats in, and I started the first float on the range that I had the night before. I just went down-stream some distance, and got into a range and put in another set of floats and let them go on down, and I waited there or went back and

met the other floats and took them out when they reached that range so that the total time that it took the float to go from Mossville down to the highway bridge at Peoria, is
2985 somewhere in the neighborhood of 19 hours.

Q. Could you give me from your data the exact time?

A. Yes sir, 29 hours and 59 minutes.

Q. From Mossville to Peoria bridge?

A. No sir, from Chillicothe.

Q. From Chillicothe to Peoria Bridge?

A. Yes sir.

Q. Now that was through a part of the Illinois River called Peoria Lake, was it not?

A. Yes sir.

Q. The progress of the floats even in this high water through Peoria Lake was very slow?

A. Yes sir.

Q. Do you know whether you kept your floats in such current as actually existed in Peoria Lake?

A. I don't quite catch your meaning. They must have been in the actual current to have made that time. As to whether the float could have been put through that lake in quicker time that than, I can't say definitely.

Q. At that time Peoria Lake was a very wide body of water to have a river running through it?

A. Yes sir.

Q. Well, did you endeavor in Peoria Lake, so far as your observations would allow you, to keep the float in the fast-
2986 est current you could find?

A. No, not entirely. On the upper part of that lake, or, not the upper part,—the part below the upper highway bridge, there was a time in there when the wind was very high, and it was not any too safe to be out with a light boat, and for that reason I didn't spread as many floats out as I otherwise would. I always had two, and part of the time four floats going through there.

Q. Did any one float along uninterruptedly from Mossville to Peoria?

A. I should say not. I could tell by looking through the records, but without doing that I should say no, for one reason. Well, I can answer right off-hand that they did not, because the way I was doing the work one float couldn't possibly go through; there was only twelve hours between starting and finishing.

Q. Now in making sub-sections from Chillicothe to Peoria, did you make more than one?

A. Oh, yes.

Q. How many times did you go ahead of floats that were in the water and start others on some range line?

A. Nine sections.

2981 Q. That is, you put in floats at nine different places and allowed them to run free, and waited for the floats up the river, to come to that range line.

A. What I did was, in the morning I put in a set of floats. I would then drop down about a mile or a half a mile and put in another set of floats. It took the first set of floats 57 minutes to get down to the range where I had started the second set of floats. I followed those floats for a while and dropped down and put in some more on a range. The second set of floats were in the water one hour, fifty-five and a half minutes. The third set were in two hours and 45 minutes, and the next set 3 hours and 28 minutes.

Q. That would be the fourth?

A. Yes sir, the fourth.

Q. What about the fifth?

A. The fifth were in 2 hours and 8 minutes.

Q. The sixth?

A. Three hours and 38 minutes.

Q. The seventh?

A. One hour and 26 minutes.

Q. The eighth?

A. 53 minutes.

Q. And the ninth?

A. 34 minutes. That is the 9th instead of the 10th.

2988

CROSS-EXAMINATION,

By Judge Springer.

Q. Did you note the movement of the floats in upper Peoria Lake, opposite the city of Peoria?

A. Yes sir.

Q. Have you a record of the movement there?

A. Yes sir.

Q. Will you refer to it please?

A. I have the record here.

Q. State if you please what time the float entered the upper part of Lake Peoria?

A. What do you mean by the upper part of Lake Peoria?

Q. The place called the Narrows, above the City of Peoria?

A. You mean there by the Narrows, the point where the upper highway bridge is, or do you mean the Narrows farther up, just below Spring Bay?

Q. I mean the narrows above Peoria, where the river below them widens out into what is called Lake Peoria.

A. Well, I hardly know how to locate the point. I will tell you. I am not very familiar with only going over it, and if I understand it, Peoria Lake runs away up the river above Peoria. Now just below Spring Bay, the town of Spring Bay, is what you call the Narrows, up there. The lake widens out and a number of points go out into the Lake, but I think it is quite wide until it gets down to where the highway bridge
2989 is across, about three miles above the city of Peoria, and if you mean that point, I can give it to you definitely, or if you mean the Spring Bay Narrows, I can give that definitely.

Q. Well, I desire to learn the velocity of the float in Peoria Lake, if you have a note of that, so as to indicate the velocity at that place?

A. I will have to work it out for you definitely; that is, the time here is not continual, on account of putting in and taking out the floats; I would have to add the different times in order to give it to you.

Q. Did you notice a material increase or decrease in the velocity of the float while it was in Peoria Lake?

A. There was a very decided difference in the velocity of the floats in going through the narrows or through the lake.

Q. How does the velocity in the lake compare with the ordinary velocity of the river?

A. I cannot answer that definitely, because I have never figured it out. These record books were turned over to Professor Van Ornum, when I came back from doing the work, and they have not been in my possession until yesterday.

Q. Then you did not note the velocity of the float in the upper lake harbor?

A. There are two ways of answering that. I did not note
2990 the definite velocity that the floats were making, but there is data enough in the notes to figure out that velocity.

Q. That you have not done?

A. No sir.

Q. If you have an opportunity during recess today, I wish you would figure that out in your notes and be able to state it after adjournment today. You can do that, can you?

A. Yes sir, but in doing that you will have to understand that it is done in making an approximate distance. For instance, I can simply say that it is approximately three miles from the upper highway bridge, to the highway bridge in the middle of the town and on that basis I can figure it, or I can give you the definite time between those two points and you can get the correct distances and figure it.

Q. That will be sufficient.

CROSS-EXAMINATION,

By Mr. Todd.

Q. At any time that these floats were going down the river, what was the character of the wind; was it high or low?

A. All the way from nothing to 24 miles an hour.

Q. When the wind was 24 miles an hour, how often would you take the floats out of the water?

A. We took them out of the water and turned in.

Q. That is, you didn't continue the experiments?

2991 A. Yes sir, we had to quit.

Q. Well, when the wind was ten miles an hour?

A. We continued.

Q. And how often did you take the floats out of the water then?

A. As often as was necessary.

Q. And how often did that appear to be necessary?

A. Well, sometimes the floats—I can show the records here, where the floats were taken out of the water, once on an average of every five minutes; that is, one float; that is where I was running five floats.

Q. What was the cause of taking it out?

A. As a rule the cause was that the current is not or was not following the channel of the river, the country was overflowed, and there was a tendency of the float to leave the river and go out across the point, so that you had to be continually taking up a float that was on the inside and taking them out and putting them on the other end of the line.

Q. Was that generally in the direction the wind was blowing, or the opposite direction?

A. Why the wind cut very little figure in that I think, with the exception of the past part of the day that we quit above Henry, about 7 miles above Henry. On that day the wind was very high and there was a very heavy swell and the float
2992 showed a tendency to work with the wind. Now I didn't realize that the wind was so high that day.

Q. How high was the wind that day?

I think that I estimated it at about 15 to 20 miles an hour late in the day, and I have forgotten now whether it was that day, or the day following that the signal service in Chicago registered it 24 miles an hour.

Q. When the wind was high enough to create waves, would the waves have any tendency, or rather any effect on the floats?

A. Very little. The floats ran quite steady. There would be some rocking of the floats, but I think that on an average you might say that it had very little effect on the velocity. The only reason for my saying that is, that I had two kinds of floats. One of them was simply a picket like they use in buiding a picket fence, about 1 1-8 inches square, and on the bottom of it were two sheets of tin that were 10x16 inches and bent at right angles. They were nailed on the different sides of the stock so that it gave practically the same effect to the float as the float that is exhibited here, but it had no cone or buoy at the top, so that the only surface that the wind could act upon was from four to six inches of the picket, 1 1-8 inches square, and a little piece of wire may be, six inches long, which is not a great deal larger than a pin, and a little piece of wrapping cloth, say four by six inches.

2993 Q. At any time that the wind was blowing did you ever remove the floats out of the river when they had gone towards the side of the stream from whence the wind was coming?

A. I couldn't say definitely that I did. On the piece of river just below Ottawa, there is quite a bluff along there, and part of the time the wind was blowing away from the bluff and part of the time it was blowing toward the bluff, depending on the direction of the river, and the floats appeared to want to follow the bluff all the time, notwithstanding that the wind part of the time was blowing away from it. Now I found the same thing in the drainage canal. That owing to the rock piled up on one side of the drainage canal, that the tendency of the float was to go in the direction the wind came from, as though the wind came over the bluff and created a suction.

Q. The tendency, you say of the float was to go in the direction that the wind came from?

A. Yes, in those cases that I speak of.

Q. And did you attribute that tendency to the wind?

A. Well, in the drainage canal I didn't know what else to attribute it to, but in the river below Ottawa, it might have been the wind, or it might have been an under-tow in the river. The wind driving the surface of the water in one way and the water flowing back and taking the float in the opposite direction.

2994 Q. You are not able then, to arrive at any definite conclusion as to the effect of the wind upon the floats in the drainage canal?

A. In going through the drainage canal the wind was not high, it was a light breeze.

Q. Did you find any other explanation as to why the floats went in the opposite direction to the wind, except what you have given?

A. No sir.

RE-DIRECT-EXAMINATION,

By Mr. Jeffries.

Q. The real reason why the float went in the opposite direction from the wind was what? State whether or not it wasn't the current that carried it,—the current of the river?

A. You ask me to state it definitely, and I cannot do it. The tendency of the float was gradually to work one way or the other. Now in the majority of cases, I think you can say it was the current, but at times they may act a little erratic. They may appear to be erratic.

Q. Now wouldn't the fact that the river rises, have a tendency to swell the current and throw it to one side?

A. I think you will find that would be different with different rivers.

2995 Q. You mean they go down stream if there was no current?

A. The current would take them down stream.

Q. I want you to give me again where you started the first section and where you ended?

A. From the Western Street bridge to the Bear Trap Dam at Lockport, within 100 feet of the Bear Trap Dam.

Q. You mean the Western Avenue Bridge instead of the Western Street bridge?

A. Yes sir.

Q. Where did you commence on the second section?

A. At Morris, Illinois.

Q. Where did you go to?

A. To a point seven miles above Henry.

Q. Now where was the third section?

A. From Chillicothe to Peoria.

JUDGE SPRINGER: State where in Peoria you ended?

A. The highway bridge, about the center of the town.

ADJOURNED until 2:30 P. M., same day, Wednesday, May 6th, 1903, at City Hall, St. Louis.

2996 City Hall, St. Louis, Missouri, 2:30 P. M., Wednesday, May 6th, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

C. V. MERSEREAU,

resumed the stand for further cross-examination by Judge Springer, and testified as follows:

Q. This morning Judge Johns asked you to state the length of the last division of the Illinois River in which you made your experiments. You could not state it at that time. Have you since obtained that data?

A. Yes sir, I can give you that in just a moment (witness refers to book). It is approximately 24 miles.

Q. Approximately 24—that is, between what points?

A. That is between Chillicothe and Peoria.

Q. Now, I requested you this morning to furnish the data from which you estimated the velocity of the flow in Lake Peoria. Have you obtained that data?

A. Yes sir.

2997 Q. Will you please give it?

A. The total time of the float in going from the upper bridge at Peoria to the bridge at the central part of the town, which is approximately three miles, was five hours and 49 minutes, which would make one mile in about one hour and 56 minutes. It was practically one mile every two hours.

Q. One mile every two hours?

A. Practically, yes sir.

Q. What is your opinion as to what would be the velocity of the flow in Lake Peoria at an ordinary stage of water?

MR. JEFFRIES: Do you ask him that as an expert or as a layman?

JUDGE SPRINGER: I am asking him for his opinion. That would be an opinion as an expert.

MR. JEFFRIES: Objected to, as the witness is not qualified as an expert on that subject, so as to give his opinion at an ordinary stage of the water.

JUDGE SPRINGER: Now, will you answer the question?

MR. JEFFRIES: I object to the question for the further reason that the witness has not stated that he has seen the water at an ordinary stage, or at any other stage than at the time the observations were taken.

JUDGE SPRINGER: Let the objection be noted. I will ask another question.

Q. Did you observe the width of the Lake opposite the city of Peoria?

2998 A. I did.

Q. How does it compare with the ordinary width of the river above the lake?

A. I never saw the river at an ordinary stage.

Q. How?

A. I never saw the river at an ordinary stage, but at the upper part of the lake there is no question but what it is considerably wider than it would be at an ordinary stage. In other words, the river was out of its banks.

Q. You could see where the banks were however, could you not, the ordinary banks?

A. In some places you could, yes sir, from the trees and bushes along the banks.

Q. Now you can answer that question I asked you before—what is your opinion as to what would be the velocity of the flow in Lake Peoria at an ordinary stage of water?

MR. JEFFRIES: I will interpose a further objection to that, that the witness has not qualified himself as being acquainted with the various flows of water, except in this particular instance, when the measurements were made by him.

JUDGE SPRINGER: Well, in view of the objection I will withdraw the question.

Q. Did you observe the character of the water between the Des Plaines river,—the mouth of the Des Plaines River
2999 and the end of the last division in which you made examinations as to its turbidity?

A. I was not on any portion of the Des Plaines River.

Q. Well, this is on the Des Plaines River after it had received the sewage of Chicago, or the drainage canal, opposite Joliet, for instance, all the way down from Joliet to Peoria, did you observe the character of the water as to turbidity?

A. In a general way, yes sir, the water was a little turbid.

Q. How?

A. The water was a little turbid.

Q. A little turbid?

A. Yes sir.

Q. Did you see any indication of the presence of the water of Lake Michigan?

A. I think that the water in the river was more turbid than the water in the canal,—if that will answer your question.

Q. Yes. It was more turbid in the river than in the canal?

A. Yes.

Q. Did you notice the condition of the streams that were emptying into the Illinois River,—the Kankakee for instance, and the Fox River?

A. Only in a general way. Let's see, the Fox River comes in at Ottawa?

Q. Yes.

A. I think the water that was coming in from the Fox
3000 River was rilier than the water in the Illinois.

Q. More turbid you mean?

A. Yes, more turbid.

Q. How about the Kankakee River; that comes in.

A. I didn't see that point.

Q. What was the stage of the water in the tributaries, that is, the Kankakee and the Fox Rivers, so far as you noticed or observed, was it a high stage of water or low?

A. Why, I couldn't answer that question because I did not go up on the Fox River at all. I only saw the river as I came by it.

Q. Well, you saw the confluence of the two streams, of that stream with the Illinois River?

A. Yes sir.

Q. Well, what was the appearance of the water there, low stage or high stage?

A. Well, of course the stage of water at the mouth would agree with the stage of water in the Illinois River, and with a low stage it would back up in the stream so that I would have no means of judging the height of the water in that stream at all.

Q. You could tell whether it was backing up from the Illinois or whether it was crowding from the Illinois?

A. Perhaps I could if I went over and watched it to make
3001 that determination. I could tell whether the current was
flowing in very strong or whether it was dead water.
Did you observe that?

A. I did not.

C. V. MERSEREAU.

3002 **FRANK J. BROWN,**

called as a witness in behalf of the complainant, being first duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. State your name?

A. Frank J. Brown.

Q. You have testified in this case before, haven't you?

A. Yes sir.

Q. Where do you live?

A. 2754 Lawton Avenue.

Q. You are still engaged in the water works department, are you?

A. Yes sir.

Q. Here at St. Louis?

A. Yes sir.

Q. Did you do any work on the Illinois River last March, —this last March?

A. Yes sir, I did.

Q. What was the character of the work?

A. It was to ascertain the velocity of the current of the Illinois River from—I started at Peoria, Illinois, and came down as far as Naples.

Q. You had one section then?

A.Yes sir.

3003 Q. And obtained the velocity from Peoria to Naples?

A. Yes sir.

Q. Now at what point at Peoria did you start?

A. Opposite the lower highway bridge.

Q. That is the bridge that is opposite the main part of the city?

A. Opposite the main part of the city of Peoria, yes sir.

Q. Did anybody else take the distance,—or rather time the velocity above that?

A. Yes sir, I understand Mr. Mersereau or Mr. Reed was there above that point.

Q. What did you do with the field notes that you made during that period?

A. I returned them to Professor Van Ornum of the Washington University.

Q. Professor Van Ornum?

A. Yes sir.

Q. Now can you state the time that it required the floats to come from Peoria?

A. Yes sir, the total distance was 71 hours and 40 minutes.

Q. Between what places?

A. From Peoria, Illinois to Naples, Illinois.

Q. What kind of floats did you use? Those that were furnished you by Professor Van Ornum?

3004 A. Yes sir, I had six floats, one, two and three feet submerged.

Q. One, two and three feet submerged?

A. Yes sir.

Q. You made a continuous run, did you, night and day?

A. No sir.

Q. Well now state what you did with refrence to stopping, or rather, removing the floats from the water and re-depositing them the next day?

A. Well, I started the floats at 3:15 at Peoria, Illinois, March 14th, and arrived at Pekin, Illinois at 7:45 that day.

Q. What did you do—

A. I took them out of the water at the highway bridge at Pekin and took them over to the hotel until the next morning and then took them out the next morning and put them in the water at the same point that I took them out the night before, and started them down the river.

Q. Now state whether you put them in the current of the river or on the side?

A. Yes sir, in the current, as near as I could possibly place them.

Q. What day did you finish your observations?

A. March 21st.

Q. March 21st?

A. Yes sir.

3005 CROSS-EXAMINATION, BY JUDGE JOHNS.

Q. Did you put the floats in at any stated distance from each other at Peoria?

A. Yes sir, I started them about fifty feet apart, probably, about that, I guess, yes sir.

Q. In going from Peoria to Pekin, did you have to take them out of the water because they grounded?

A. Some of them, yes.

Q. How many times?

A. Why, I don't know. There was several times I had to go to shore; I had to take them out.

Q. On the right bank of the river going down?

A. Well, partly. Not altogether on the right bank;—partly on the left. Partly on the right bank, and partly on the left, yes sir.

Q. Which was the most?

A. I think it was on the right bank, that was the most, if I remember it.

Q. The river from Peoria to Pekin is quite tortuous?

A. Yes it curves around.

Q. At Pekin did you put them in at this same distance,—about fifty feet apart?

A. Yes, just about that.

3006 Which float traveled the most rapidly—what ones?

A. Why, I think that the one-foot submerged floats made a little the best time in my experience.

Q. Made the better time?

A. Yes sir.

Q. Which was the slowest?

A. Well, the three-foot was the slowest, except in case of high winds up-stream, and if anything they would fall behind, but in the ordinary current or wind, the red floats made the best time.

Q. If the wind was high, and blowing up-stream?

A. The three foot floats made the best time.

Q. Would travel the most rapidly?

A. Yes sir.

Q. Did you take any guage readings along the route?

A. Yes sir.

Q. Where did you read guages?

A. At Peoria, where I started, and at Pekin, at the Copperas Creek dams—the State Locks, as they call it; at Havana, Government locks and Beardstown, and at Meredosia.

Q. Have you the guage readings for those various places?

A. Yes sir.

Q. Give them please?

A. The guage at Peoria, at the starting place, was 19.

3007 Q. Do you understand that was 19 feet above zero?

A. Yes sir.

Q. Well, go on and give the guages at the different places respectively, and the day of the month on which you read them?

A. That was March 14th.

MR. JEFFRIES: You say that guage at Peoria was March 14th?

A. Yes sir. Guage on bridge at highway—highway bridge at Pekin, Illinois, Sunday, March 15th, was 13.6. The guage at the State Locks, same day, at 6:35 p. m., was 17.5.

Q. JUDGE JOHNS: Is that the Copperas Creek dam?

A. Copperas Creek dam, yes sir. And I also took the readings at the Copperas Creek dam the next morning, sir, when I started out at 7:27 and it was 17.5. At Havana, Illinois, March 17th, at 4:20 P. M., the gauge at the highway bridge was 16.9. On March 19th at 6:15 P. M., the gauge at Beardstown, Illinois, was 16.10. At Meredosia, March 21st, at 8:40 the guage was 17 feet, nine and one-half.

MR. JEFFRIES: 8:40 in the evening or morning?

A. 8:40 A. M. And on March 20th, the government locks, at 2:02 P. M.,—there is two guages there, called the upper guage and the lower guage of the Government Locks.

JUDGE JOHNS: At La Grange?

A. Yes, just below the boat landing at La Grange, about a mile. It was 24.50 at the upper end of the locks, and the
3008 lower end was 24.25. That is all the guage readings I have.

Q. How many hours and minutes from Peoria to Naples?

A. 71 hours and 40 minutes.

Q. When you took out the floats each time at the place where you stopped, you took out the first one that arrived?

A. Yes sir.

Q. You endeavored to keep the floats in the current of the river as much as possible?

A. Yes sir.

Q. And in the most rapid current?

A. Out in the current as near as it was possible, just as direct in the current as we could get them.

Q. When a float went astray and got out of the current, or went aground, you took it out and put it in the current, opposite where you took it out?

A. Yes sir.

Q. Did you have a boatman?

A. Yes sir.

Q. How many?

A. One.

Q. Who was he?

A. His name was Henry Clay.

Q. Where did Henry live?

A. At Peoria, Illinois.

Q. Can you give his street number and address?

3009 A. Foot of Bridge Street, was his Post Office address, Peoria, Illinois.

CROSS-EXAMINATION, BY MR. TODD.

Q. You said something about the floats, in regard to their situation depending upon the wind, whether the wind was upstream or not—what was the statement?

A. What was the statement?

Q. Yes?

A. Well, I said with a very high wind blowing up stream the three foot submerged float made a little the best time. At least I think so according to my observation.

Q. The three foot submerged float?

A. Yes, in a high wind.

Q. How high a wind did you have?

A. Well, 25 miles an hour,—twenty or twenty-five miles an hour.

Q. Did you have wind 25 miles an hour?

A. Well, I didn't have anything with me to measure it, but I think at one time it was fully that much, yes sir.

Q. Well, any wind under 25 miles an hour wouldn't effect the floats, would it?

A. Yes, it would not necessarily have to be that strong;

twenty-five miles it would have some effect upon it, blowing directly up stream. 3010

Q. Have you ever had any experience in a wind of 25 miles an hour?

A. No sir, none whatever, except the cyclone in St. Louis, that's all.

Q. Do you know what the speed of that was?

A. About eighty five.

A. How did you arrive at that conclusion that the wind was 25 miles an hour?

A. Because it was a very strong gale,—a very strong wind.

Q. And it might have been 50 miles an hour as far as your observation goes?

A. No, it wasn't that—no I don't think so.

Q. Well, have you any experience in regard to the velocity of wind?

A. No sir. I told you that before—none whatever.

Q. Well then, how did you fix 25 miles an hour there?

A. That is my observation of the matter; what I thought about it.

Q. Well, if you had no experience in that line, was there anything that would enable you to draw that conclusion?

A. Well, I think—

Q. Except a pure guess?

A. That's all, just a pure guess, as I had nothing to measure it by, whatever.

3011 Q. Now would those conditions obtain in a lighter gale than the one which you spoke of?

A. Well I said when the wind blowed strong,—I would say ten miles, that is an ordinary gale, the white float would make a little the best time; that is my idea.

Q. That then, doesn't obtain only in these heavy gales?

A. Any ordinary gale.

Q. Any ordinary gale?

A. Yes sir, it is a pretty strong wind when it is blowing directly up-stream.

Q. How did this wind affect the floats?

A. Well, I don't know; I couldn't answer that question, how it affected them.

Q. I mean, what appearance did it have on the floats at eight or ten miles an hour say?

A. The only way I could answer that question,—the one foot submerged float didn't make as good time as the others. I noticed that it dropped behind considerably; that is all I could tell you.

Q. Most of these floats were floats with conical tops, with a flag, weren't they?

A. Yes sir.

Q. When the wind was down stream, what effect did it have on them?

3012 A. Well, in my experience on the river, there was a very little wind blowing directly down stream, but when it did blow down stream, it was very light.

Q. Well, the wind you speak of, didn't blow down stream all the time, did it?

A. Oh no, just only came up once or twice.

Q. Did the wind blow across stream?

A. Yes sir.

Q. What effect did it have when it blew across stream?

A. I couldn't answer that question.

Q. Would it affect the six foot float as much as it would the four float?

A. No sir, whenever the wind was across stream, an ordinary breeze—

Q. Well, a ten mile an hour breeze?

A. Across stream it would not effect it at all, I don't think. Not so much as I could notice it.

Q. It was only wind which was blowing up-stream that would affect them?

A. I noticed that the white one would make better time.

Q. When it was blowing up-stream, was the white float exposed anymore to the wind than the deep one?

A. I don't know what was the cause of it. The others dropped behind a little bit.

Q. That was merely a coincidence then?

3013 Well, the coincidence happened every time it blowed.

Q. When the wind blew up stream, why the floats didn't go down as fast?

A. I don't know, about as fast—

Q. I mean, the two floats didn't go down the stream with uniform regularity?

A. One didn't go quite as fast as the other.

Q. But at other times they would go with uniform regularity?

A. Yes sir.

Q. And when the wind was blowing as a gale, ten or fifteen miles an hour did you take the floats out of the water at any time?

A. No sir.

Q. Did you take the floats out of the water at any time in making these different experiments?

A. No sir, except when they would get grounded on shore or something of that kind.

Q. How?

A. They would drop way behind and go to one shore or the other; I would have to take them out. That is the only times.

Q. When they would get out of the channel you would take them out and put them back in the channel?

A. If they would get too near the shore or get aground, yes sir.

Q. Did that happen frequently?

3014 A. Well, from Peoria down to Havana I had some trouble with them, but it didn't seem to bother me so much after that.

Q. What seemed to be the cause of it?

A. Well, I don't know, unless it would be the wind blowing from the bank, driving them over that way.

Q. The wind blowing from the bank?

A. I noticed, which way the wind was blowing, the floats always go that way.

Q. The floats would always go with the wind?

A. Yes sir, across the stream.

Q. Across the stream?

A. Yes sir.

Q. And the wind had a perceptible influence on the floats?

A. It seemed that way, in going across, yes sir.

Q. Now when the wind would come up at a ten mile an hour gale, how far would the floats go before they would strike the shore?

A. Oh, it would sometimes be a couple of hours.

Q. And then would they go across sooner than that?

A. Oh, I think that if they were out in the current, ordinarily they would go two or three hours without running ashore.

Q. How many times did you take up the floats from Peoria to Havana, and put them in the current?

3015 A. Took them up—I had six of them you know, and sometimes the six of them would run nearest to the shore and run aground, and I would take one up—occasionaly it would get caught in the drift-wood.

Q. But the wind did have a perceptible effect upon the floats?

A. I noticed it, in going across, yes sir.

RE-DIRECT-EXAMINATION, BY MR. JEFFRIES.

Q. When you took one of these floats out of the drift-wood, or its place of lodgment, you took it back to the channel and relocated it in the channel where?

A. Right opposite the float—

Q. That was running on?

A. That was running on, yes, sir.

Q. Not opposite the place where you took it up from then?

A. No, sir.

Q. You stated in answer to Mr. Johns a moment ago, you put it in opposite the place where you took it up.

A. No, sir; I placed it opposite the float that was in the current.

FRANK J. BROWN.

3016 JOSEPH E. GIBSON, called as a witness in behalf of the complainant, being first duly sworn, was examined in chief by Mr. Woerner, and testified as follows:

Q. State your name?

A. Joseph E. Gibson.

Q. Where do you reside?

A. 2753 Lafayette avenue, St. Louis.

Q. What is your business?

A. I am employed in the water and construction departments.

Q. How long have you been in that employ?

A. Fourteen years.

Q. Did you make any observations in March last of this year, in order to ascertain the rapidity of the current of the Illinois river?

A. Yes, sir.

Q. State what you did and when you did it and the manner in which you did it?

A. I started from Naples, Illinois.

Q. You started from Naples, Illinois, and went up where?

A. No, sir; I started from Naples and went down to Grafton.

Q. Do you know who the man was immediately above you, who made the observations of the river above the place where you began?

3017 A. Yes, sir.

Q. What was his name?

A. Mr. Brown.

Q. What one took up the observations after you left at Grafton; who was that?

A. Professor Van Ornum.

Q. Now, just state in detail the manner and method and time in which you made these observations and what the result thereof was?

A. I was 30 hours and 37 minutes from Naples to Grafton; that was the total time of my time consumed in making the trip.

Q. That was the aggregate time of what?

A. From Naples to Grafton, from the time the floats were in the water.

Q. You made experiments with floats, did you?

A. Yes, sir.

Q. Like the gentlemen who have testified heretofore?

A. Yes, metal floats, submerged floats—three foot chains, a foot and a half and a foot—the length of the chains.

Q. Did you follow the floats in a skiff?

A. Yes, sir.

Q. Anybody with you?

A. Yes, I had a skiff man.

Q. Where did you hire him?

3018 A. In Naples.

Q. Did he go with you the whole way?

A. Yes, sir.

Q. Did you travel during the day time only?

A. Sir?

Q. Did you travel only during the day time?

A. During the day time only, yes, sir.

Q. What did you do at night?

A. Well—

Q. Stay on the bank?

A. If we could get a good comfortable place to stay all night, we stayed all night.

Q. Well, you ceased to do anything at night?

A. We didn't do anything at night at all.

Q. Then you started in the morning at the same place?

A. The same place we took the floats out.

Q. Go on and tell what you did and what the result of it was, just as near as you know how.

A. Do you want those gauge readings, etc.?

Q. No, sir; not yet.

Q. Just state how you did it from point to point?

A. Well, I started from Naples with three floats, and from Naples to Bedford I was 7 hours and 50 minutes. That was on March 18th, and from March 19th, from Bedford, opposite the government light to three miles below Kampsville, there 3019 is where I took the floats out for the night. That is, the distance or time approximately was 9 hours and 40 minutes, and that was the time consumed between those two points. On the 20th I started the floats opposite the government light three miles below Kampsville, the same point I just referred to and took them out opposite the government light, about nine miles above Grafton. That was 9 hours and 5 minutes consumed in that run. On the 21st I started the floats opposite the government light 9 miles above Grafton to a little island opposite Grafton. There is where I took the floats out. The time was 4 hours and 2 minutes.

Q. Making an aggregate for the entire distance covered by you of how much?

A. Thirty hours and 37 minutes.

Q. Did you have all the floats when you stopped?

A. Yes, three. I started with three and finished with three.

CROSS-EXAMINATION, by Judge Johns.

Q. State where you took the gauge readings when you took them, and the readings.

A. I will have to go through my note-book and get those out. At 9:45—

Q. A. m. or p. m.?

3020 A. 9:45 a. m. That was the day they started, on March 18th. The gauge reading equals 18 feet 2½ inches. This is in inches. Gauge on draw-bridge opposite Valley City, Wabash draw-bridge. On March 19th, arrived at 9:35 a. m. Arrived at Chicago & Alton draw-bridge. Gauge reading equals 16 feet 6 inches.

Q. Was the gauge in feet and tenths?

A. The government gauges are all in tenths, but those railroad gauges are not.

Q. Where did you read a government gauge?

A. At the government locks at Kampsville. I will get to that in a minute. I forget the name. The government locks at Kampsville. That is the only government gauge I read. March 19th, 3:07 p. m. Arrived at government locks on right bank—that is at Kampsville. The reading equals 24.7.

Q. Was that gauge above or below the locks?

A. It is above the dam.

Q. Did you read any gauge below the dam?

A. No, sir; there is only one gauge there.

Q. Was the dam at Kampsville visible?

A. No, sir; I asked the keeper there in regard to that and he said there was about 11 feet of water over the dam. Saturday, March 21st, 10:11 a. m. Arrived at Grafton and the gauge reading there was 17.0. That is the only gauge readings I have.

3021 Q. Which one of your floats traveled the most rapidly?

A. Well, that is pretty hard to say; I could not distinguish much difference in them.

Q. What kind of weather were you having on the first day you were out?

A. We had a very nice day the first day. It was clear. The weather was clear.

Q. You didn't run into any 25 mile an hour gale?

A. No, sir.

Q. Did you keep a record of the journeyings of each one of your floats?

A. Yes, sir.

Q. Have you them numbered?

A. Yes, sir.

Q. When you arrived at the place where you took out the floats, you took out the one that arrived there first, didn't you?

A. Yes, sir.

Q. And kept the time for that?

A. Yes, sir.

Q. You kept the floats as much as you could, in the current of the river?

A. Yes, sir.

Q. Did your floats ground sometimes and run into the drifts?

3022 A. Well, sometimes they would drift out on the edge of the bank.

Q. And when they did, you would take them out and put them in the current opposite where you took them out, as closely as you could?

A. Yes, sir.

Q. Do you know which one of your floats drifted out the most?

A. No, sir; I couldn't say that.

Q. Did you have a compass?

A. No, sir.

Q. Did you keep the direction of the wind?

A. No, sir.

Q. You made no notes, field notes of anything except the time you put in the floats and took them out?

A. I took field notes of the wind and the usual direction with reference to the bank, up or down or partly from the right or left bank.

Q. Without regard to the points of the compass?

A. Yes, sir.

Q. Which was the prevailing wind, up the river or down the river?

A. Mostly up-stream.

Q. Well, from what general direction was the wind on the first day, say?

3023 A. Well, up-stream mostly, from the right bank, I think my note-book showed.

Q. That means the right bank of the river as you were going down stream?

A. Yes, sir.

Q. Now, the second day, what was the direction of the wind?

A. Partly from the right bank, I think. I have that next day.

Q. And the third day?

A. The third day was almost due up-stream. We had a severe wind that day, too.

Q. A higher wind?

A. Yes, sir.

Q. Now, which one of your floats went the most rapidly that day?

A. Well, they all kept pretty close together. I couldn't tell much difference.

Q. You couldn't tell any difference?

A. No, sir.

Q. Did they seem to drift off toward the bank in the direction in which the wind was blowing?

A. Well, I think it had a kind of a tendency to draw them over at times.

Q. The river was very high, wasn't it?

A. Yes, sir.

3024 Q. Out all over the bottoms?

A. Yes, sir.

Q. When there was considerable wind, there were waves in the current of the Illinois River?

A. Very rough, yes, sir.

Q. Sometimes quite rough?

A. Yes, sir.

Q. If the wind was from a general direction south, it would either blow up stream or at an angle across stream?

A. Yes, sir.

Q. When the waves struck these floats, it seemed to knock them over in the direction which the waves ran, didn't it, a little?

A. Yes, that had a tendency to work that way somewhat.

Q. There was a visible effect of that character?

A. Yes, sir.

RE-DIRECT EXAMINATION, by Mr. Woerner.

Q. Are you able to state whether or not, when the wind blows up-stream, it affects the floats to any extent?

A. When the wind is due up-stream?

Q. When the wind blows up-stream, and the floats are floating down-stream, whether the floats would be retarded more than they would be if the wind wasn't blowing?

A. I don't think it would have much effect on them, no,
3025 sir; not the wind I encountered.

Q. You do not think that that would have much effect on the floats at all, then?

A. No, sir.

JOS. E. GIBSON.

3026 THOMAS F. REED called as a witness in behalf of the
complainant, being first duly sworn, was examined in chief, by Mr. Woerner, and testified as follows:

Q. What is your name?

A. Thomas F. Reed.

Q. You live in St. Louis?

A. Yes, sir.

Q. What is your occupation?

A. Rod man in the water department.

Q. How long have you been in the water department?

A. A little over thirteen years.

Q. Mr. Reed, did you take part in any observations, the object of which was to determine the velocity of the flow of the Illinois River last March?

A. I did; yes, sir.

Q. State first, in a general way, what portion of the river you covered?

A. I covered from Lockport to Morris.

Q. The whole of it?

A. The whole of it; yes, sir.

Q. Any other portions of the river?

A. And from seven miles above Henry to Chillicothe.

3027 Q. Any others?

A. No, sir; that's all.

Q. Those two portions then, were assigned to you?

A. Yes, sir.

Q. Now, you started at Lockport, you say?

A. At Lockport, yes, sir; at the Bear Trap Dam at Lockport.

Q. Now, just state in detail what you did and the manner and method in which you proceeded and the dates, and the result of your observation?

A. I started two floats at the Bear Trap Dam on the 16th of March, and one of them started down the river all right, and the other I couldn't keep track of, so I just followed the one at that time, that is, on the 16th, and I followed it as far as Joliet and took in the float the night of the 16th, just below the McDonnough Street Bridge in Joliet. On the morning of the 17th, I started at the point I left off the night before, with two floats, and it was very foggy, and I lost track of the two floats, and I got out of the skiff and walked down as far as the Brandon Street Bridge, and that was the last I seen of the floats. I sent the boatman back to look after the floats, and I went back to Joliet to have two more made.

Q. You did what?

A. I went back to have two more new floats made. I only had one. I knew it was the only chance I would have to get any floats to finish the trip. And I started again. I will have 3028 to look at my notes to see what time I started.

Q. Those are the notes that you made at the time?

A. Yes, sir; I have the notes in the book here. That is the only way I can explain. I have the original notes here in the note book.

Q. You can tell by refreshing your memory from the notes then. Before we go on, Mr. Reed, I wish you would state how long it took you from the place where you started down to Joliet, as you have stated?

A. Down to Joliet or to Morris, do you mean? From Lockport to Joliet it took me 2 hours and 15 minutes the first day.

Q. Is that from the place you started?

A. Yes, from the place I started at the Bear Trap Dam.

Q. That took you how long?

A. Two hours and 15 minutes, where I took in the floats for the evening.

Q. That is Joliet?

A. Yes, sir; that is Joliet.

Q. Now, go on further?

A. On the next day from Joliet to about two miles and a half above Millsdale, it took me 3 hours and 35 minutes; that is, from the time I started to make the run over again after losing the floats.

Q. Those are the new floats?

A. The new floats, yes, sir.

3029 Q. What date was that?

A. The 17th of the month. It took me 3 hours thirty-five and a half minutes to go two miles and a half about, above Millsdale. I took in the floats in the evening. I started from Millsdale the next morning and it took me three hours and six minutes to get to Smith's farm. I had a very bad boat and the water was very rough and I couldn't handle the floats, so I took the floats in and stopped there, and the weather was very bad all day and I just took the floats in for the day. The waves were very high and I had a very bad boat. It was a very dangerous part of the river and the boatman was afraid to make the trip.

Q. You needn't state the reasons why. Just state what you did.

A. I took the floats in that evening. From Smith's farm the next morning, to Morris, it took me 9 hours and 24 minutes to get to Morris, from where I left off the morning before, 9 hours and 24 minutes. The total number of hours it took me to get from Lockport to Morris, is 18 hours twenty minutes and a half.

Q. You have got down to Morris now?

A. Yes, sir.

Q. Now, that is where you stopped that part of your trip?

A. That is where I stopped my part of the trip.

3030 Q. Now, then, who took it up from that point where you quit on the way down immediately below you?

A. From that point to seven miles above Henry, Mr. Mersereau and I made the trip. From Morris to seven miles above Henry, Mr. Mersereau and I made the trip.

Q. Then the part you have narrated, you went yourself?

A. Yes, from Lockport to Morris.

Q. And from Morris down, you and Mr. Mersereau together made the trip?

A. Yes, sir; together. I recorded—

Q. Now, continue with just what you and he did together, as briefly as possible?

A. Well—

Q. That portion of it which you and Mr. Mersereau did?

A. I was just looking over these notes here, the part I did.

Q. You can give us the aggregate time it took the floats, can you?

A. No, sir; I cannot.

Q. Well, then, where did you go on again after that?

A. From seven miles above Henry to Chillicothe.

Q. Now, when did you start from the point seven miles above Henry?

A. On the 25th of the month.

Q. Now, go on and narrate that part of it.

A. It took me 10 hours and 25 minutes from the point
3031 about seven miles above Henry to about two miles below
Henry. Now, I will have to look up the time on the 26th, from Henry on down. I haven't had a chance to look up these notes. I haven't had any time to look them up and this is the first I have seen of the book since I turned it in. It took me 11 hours 18 minutes and a half to make the trip from two miles below Henry to Chillicothe.

Q. You mean by that, that it took the float that long?

A. It took the floats that long, 11 hours 18 minutes and a half.

Q. Well, is that where you left off?

A. That's where I left off, at Chillicothe, yes, sir.

Q. What day or dates did that cover?

A. This is on the 26th of the month, the 26th of March.

CROSS-EXAMINATION, by Judge Johns.

Q. Did you have a boatman or an oarsman at Lockport?

A. Yes, sir.

Q. Who was he?

A. Why, he was a boatman that I picked up—a river man whose name was Garver. I haven't his address.

Q. Does he live in Joliet or Lockport?

A. Yes, I think he lives in Joliet.

3032 Q. James Garver?

A. George Garver was his name.

Q. What happened to your float that you lost at Lockport?

A. Why, I put the float in on each side of the dam and one float went down the river all right, and the other cut around the mouth of the Desplaines river and got in the brush there in the willows and of course I started on down after the float that was in the channel of the river and just let the other one go, it was speeding pretty fast and I was afraid I would lose it, and it was in the channel of the river, in the current of the river, so I just let the other one go and paid no attention to it at all.

Q. How far did you put in the one you lost above the dam or right at the dam?

A. Just above the dam in the canal, I put one on each side of the dam.

Q. One below the dam and one above?

A. No, sir, not one below and one above; both of them were above; both went over the dam at the same time on each side of the dam of the canal.

Q. Which one got lost?

A. The one that I started on the—

Q. The right bank of the canal or the left?

A. It was on the right bank of the canal.

3033 Q. How far did you observe that float?

A. Well, I didn't see it a very few minutes after it started. I struck right down after the float that was in the channel of the river.

Q. This one that was lost, did it go across the Desplaines river?

A. It went across the Desplaines river and came on down as far as the bridge. It went across the Desplaines river; then

I picked this float up and I started with it again later on, after the float got down as far as the bridge. The first float, I timed it at the bridge, and I went back and picked up the other one.

Q. Where did you find it?

A. I found it in the river going down the river. It had gotten tangled up in the willows. I took it out just above the bridge and started it in at the bridge again, and that was the last I seen it. I took it up after I started it from the dam. The other float I started down the river; I started it after that and took the time of this float; then I went back and picked up this float that was tangled in the willows between the bridge and the mouth of the Desplaines River, picked it up and started it again at the bridge.

Q. When you got to this first float, was it stopped or floating?

3034 A. Yes, sir; it was in a lot of brush.

Q. How far from the dam?

A. I didn't make a memorandum of that and I couldn't tell you exactly. It was between the dam and the bridge.

Q. Well, how far is that?

A. Well, an eighth of a mile.

Q. When you went back and put it back in the river again, and floated it down to the bridge?

A. Well, I will look up my notes and read the notes to you.

Q. Well, cannot you recollect independently of your notes what happened to your float after you picked it up?

A. After I picked it up I started it again at the bridge and that was the last I seen of it. I lit down after the other float and didn't pay no attention to it at all. I just let it go.

Q. You lost it entirely that time?

A. Lost it entirely, yes, sir.

Q. When you had the floats made at Joliet, what kind were they?

A. They were the same we started with. I just got one of the old floats and had it as a pattern and had two made just exactly like it.

Q. Tin floats?

A. Tin floats, yes, sir.

3035 Q. With submerged veins underneath?

A. Yes, sir.

Q. Of the same thickness and size?

A. Yes, sir; duplicate floats.

Q. You didn't use a picket, a fence picket, weighted?

A. I did not, on the first trip that I made, no, sir. On the first division I made I didn't use a picket, no, sir.

Q. Did you read any gauges?

A. I did; yes, sir.

Q. Where?

A. I met the gauges at the different bridges and any gauge that I passed, I read—on the bridges.

Q. Now, give me the names of the places where you read the gauges and the time of day and the gauge readings, and the date of the month.

A. It will take me some time to look that up. Ninth Street Bridge at Lockport at 3:00 p. m., the gauge on the bridge read 16.7 feet. At ten o'clock a. m. on the 18th of the month. This is at the mouth of Jackson Creek, I read the gauge 81.55.

Q. Did you know what that 81.55 signified?

A. No, sir; I did not; just as the gauge read I recorded it in the book. About three miles below Millsdale, time 12:12. This is past Charles Smith's wagon bridge in the Desplaines river, about three miles below Millsdale. Gauge at bridge, west
side tree, registered 81.1. On the 19th of the month, the
3036 gauge on the Elgin, Joliet and Eastern Railroad bridge
at 9:41 registered 87.7. That is all the gauge readings
I have on the first part of the trip, unless I have passed over some of them there. Now, do you want me to give you the readings from Henry on down to Chillicothe?

Q. Yes.

A. On the 25th of the month I didn't get any gauge readings on the 25th of March. I read the gauge on the Lacon wagon bridge at 10:44.

Q. Is that the hour of the day or what?

A. That is at 10:44 a. m.

Q. Now, what was the gauge reading?

A. The gauge reading was 18.7 feet.

Q. Did you have a boatman on this last trip down to Chillicothe?

A. Yes, sir.

Q. Who was he?

A. His name was Krafft.

Q. What is his first name?

A. I think it was George; I ain't certain (refers to book). His name was Nick Krafft.

Q. Where did he reside?

A. On a farm about seven miles above Henry.

Q. How many hours and minutes were you on this last trip?

A. 11 hours, 18 minutes and a half.

3037 Q. Now, the river was very high, wasn't it?

A. The river was very high; yes, sir.

Q. Which one of your floats traveled the most rapidly?

A. Well, I changed the floats off and on. I would start a certain number of floats in the morning, and as they would lag back I would pick up the hind float and put it up opposite the head float, as they drove into shore, you know, the ones that lagged back. I tried to keep two or three floats in the river all the time the latter part of the trip.

Q. Which one of your floats traveled the most rapidly, the one with the greater or less submergence?

A. Well, I don't know. I couldn't say.

Q. What caused the floats to move out of the channel?

A. The wind. The high wind all the time; every day we were out; the wind would drive them right into the shore, right along.

Q. What direction was the wind from?

A. Generally across stream, up-stream part of the way.

Q. Well, across stream probably in a southerly direction, going in a northerly direction?

A. I couldn't tell you; I don't know. I couldn't tell you exactly the dates or the direction of the wind; I just made notes across stream or up-stream.

Q. The wind would blow the floats in the direction the wind was blowing?

A. No sir, not necessarily.

3038 Q. Well, towards that shore?

A. Towards the shore, yes.

Q. Towards the shore in the direction in which the wind was blowing?

A. Yes sir.

Q. When you were on the second section that you were working upon the river was very wide wasn't it?

A. Yes sir, very wide from bluff to bluff.

Q. And the dams were all submerged with water?

A. Yes sir.

Q. The wind had a free sweep?

A. Yes sir.

Q. The water was sometimes quite rough?

A. Yes sir, all the time.

Q. The waves ran a foot high, did they?

A. Yes and more.

Q. More than a foot high?

A. Yes sir.

Q. Now the floats would drive in the direction in which the waves knocked them?

A. Well, I tried my best to follow the current of the river and I supposed I was in the current of the river.

Q. Well, when the floats drive—when you had to take them out, they had drifted in the direction in which the waves were running?

3039 A. Yes sir.

THOMAS F. REED.

ADJOURNED to the Southern Hotel until Thursday morning, at ten o'clock, May 7th, 1903.

3040 Southern Hotel, St. Louis, Missouri. 10:30 a. m., Thursday, May 7th, 1903.

Parties met pursuant to adjournment.

Present: The Commissioner and same counsel representing the respective parties.

No witnesses being present an adjournment was taken to Southern Hotel, St. Louis, until Friday, May 8, 1903, at 10:00 a. m.

3041 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Friday, May 8, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

No witnesses being present, an adjournment was taken until 2:00 p. m. same day.

2:00 p. m., Friday, May 8, 1903. Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

L. B. ENGLISH,

Called as a witness in behalf of the complainant, being first duly sworn by the Commissioner, was examined in chief by Mr. Jeffries, and testified as follows:

Q. State your name?

A. L. B. English.

Q. Where do you live, Mr. English?

A. 4339 Finney Avenue, City of St. Louis.

Q. You are a law clerk in the City Counselor's office of St. Louis, are you? 3042

A. Yes sir.

Q. I will ask you if you have done anything with reference to the collection of typhoid death rates in various cities along the Mississippi river to the north of St. Louis in the last two or three months?

A. Yes sir.

Q. If so, when, and state the number of places that you have examined.

A. Minneapolis, St. Paul, Dubuque, Iowa, Des Moines, Iowa, Keokuk, Burlington, Hannibal, Quincy and Fort Madison, Iowa.

Q. Now when was this done?

A. (Witness refers to book.) Commencing on the 6th of April and extending over a period up to and including April 15th, this year.

Q. Where did you go first?

A. Minneapolis, Minnesota.

Q. State the character of your examination of the records at Minneapolis?

A. I examined the records to determine the deaths per month and year from typhoid fever, and the total number of deaths.

MR. TODD: I object on the ground that the records are the best evidence, and on the additional ground that anything that he might say is mere hearsay and is not competent.

MR. JEFFRIES: Go ahead Mr. English?

3043 A. To ascertain the deaths from typhoid fever and the total number of deaths from all causes. I have got those by the month, beginning with January 1, 1893, up to and including December, 1902.

Q. You examined those records in the office of the Board of Health, did you?

A. The Health Commissioner, yes sir.

Q. In the city of Minneapolis?

A. In the city of Minneapolis.

Q. Now will you state what you found from those records?

MR. TODD: I object to the question on the ground that the records are the best evidence, and it is incompetent for this witness to testify about what the records disclose.

A. Do you want me to state them by the month?

Q. MR. JEFFRIES: First state the time of this particular examination in Minneapolis, if you have it.

MR. TODD: In order to save time, will it be understood that this objection goes to all of this? Then we won't need to interrupt?

GENERAL CROW: Yes sir. That will be understood to apply to all this class of testimony.

A. Monday, April 6th.

MR. JEFFRIES: Now go ahead and tell what you found in this record.

GENERAL CROW: That is, of this year, 1903?

3044 A. This is the examination of this year, 1903. In the year 1893—which form will be the best for the stenographer—

MR. JEFFRIES: Give the number of cases of typhoid by month, and the totals for the year, each year?

A. You don't want the cases; you want the deaths?

Q. No, I don't care anything about the cases.

A. (Witness refers to paper.)

THE COMMISSIONER: Is this one that is certified to?

A. No sir, this is not one that is certified to. This is one that I made the extracts myself. Year 1893, January, 4 deaths from typhoid from total causes—

MR. JEFFRIES: Well, you needn't put the total in; there is no use of putting that in the record.

A. You just want the typhoid?

Q. Yes, if they want it on the cross, they can put it in.

A. February, 2 deaths from typhid.
March, 4,
April, 3,
May, 6,
June, 4,
July, 16,
August, 19,
September, 27,
October, 22,
November, 18,
December, 9.

3045 Total deaths from typhoid fever for the year 1893, 134.

Year 1894:
January, 3 deaths from typhoid fever.
February, 2,
March, 9,
April, 3,
May, 1,
June, 2,
July, 7,
August, 27,
September, 13,
October, 18,
November, 10,
December, 6,
Total, 107.

Year 1895:

	January,	4 deaths from typhoid fever.
	February,	1,
	March,	2,
	April,	3,
	May,	2,
	June,	3,

	August,	8,
	September,	9,

October,	7 deaths from typhoid.
November,	10,
December,	8,
Total,	148.

Year 1898:

January,	7 deaths from typhoid.
February,	4,
March,	8,
April,	6,
May,	1,
June,	5,
July,	10,
August,	8,
September,	16,
October,	10,
November,	6,
December,	5,
Total,	86.

Year 1899:

January,	3 deaths from typhoid.
February,	3,
March,	2,
3048 April,	3,
May,	5,
June,	5,
July,	6,
August,	10,
September,	10,
October,	12,
November,	5,
December,	7,
Total,	71.

Year 1900:

January,	1 death from typhoid.
February,	2,
March,	none,
April,	3,
May,	1,

	June,	1 death from typhoid.
	July,	none,
	August,	1,
	September,	1,
	October,	1,
	November,	1,
	December	2,
	Total,	13.

Year 1901:

3049	January,	5 deaths from typhoid,
	February,	4,
	March,	25,
	April,	25,
	May,	11,
	June,	5,
	July,	5,
	August,	8,
	September,	11,
	October,	8,
	November,	10,
	December,	4,
	Total,	121.

Year 1902:

	January,	3 deaths from typhoid
	February,	2,
	March,	8,
	April,	8,
	May,	5,
	June,	4,
	July,	1,
	August,	8,
	September,	9,
	October,	4,
3050	November,	10,
	December,	4,
	Total,	66.

That is all for Minneapolis.

Q. Now you got that from the records in the Board of Health Department of Minneapolis?

A. Yes sir.

Q. You saw the records personally and examined them and made the copies?

A. Personally and made the extracts myself.

Q. Made the extracts?

A. Yes, read them to the stenographer and afterwards compared them.

Q. Now then, just refer to St. Paul.

A. (Witness refers to paper).

Q. That was made what day,—the following day?

A. Yes sir, the following day.

Q. Which would be what date?

A. That would be April 7th.

Q. 1903?

A. Yes sir.

Q. Now commencing from 1893 to 1902?

A. 1893—January, 3 deaths from typhoid,
February, 2,
March, 1,
3051 April, none,
May, 2,
June, 3,
July, 1,
August, 11,
September, 8,
October, 9,
November, 5,
December, 6,
Total, 51.

Year 1894:
January, none,
February, 1,
March, 1,
April, 1,
May, None,
June, 2,
July, 2,
August, 4,

September, 6. deaths from typhoid.
October, 5,
November, 6,
December, 4,
Total, 32.

Year 1895:
3052 January, 3 deaths from typhoid,
February, 5,
March, 3,
April, 1,
May, 1,
June, 3,
July, 4,
August, 5,
September, 2,
October, 8,
November, 1,
December, 2,
Total, 38.

Year 1896:
January, 7 deaths from typhoid,
February, 6,
March, 3,
April, 3,
May, 1,
June, 1,
July, none,
August, 5,
September, none,
October, 4,
November, 5,
3053 December, 2,
Total, 37.

Year 1897:
January, no deaths from typhoid,
February, 2,
March, 2,
April, 2,

May,	1 death from typhoid.
June,	1,
July,	none,
August,	1,
September,	3,
October,	3,
November,	6,
December,	1,
Total,	22.

Year 1898:

January,	7 deaths from typhoid,
February,	none,
March,	1,
April,	3,
May,	6,
June,	4,
July,	none,
August,	6,
3054 September,	9,
October,	none,
November,	4,
December,	3,
Total,	43.

Year 1899:

January,	2 deaths from typhoid,
February,	1,
March,	none,
April,	1,
May,	1,
June,	1,
July,	1,
August,	3,
September,	4,
October,	4,
November,	5,
December,	2,
Total,	30.

Year 1900:
January, 2 deaths from typhoid,
February, 3,
March, none,
April, 1,
May, 2,
3055 June, 2,
July, 4,
August, 4,
September, 6,

December, 4,
Total, 36.

1901:
January, 4,
February, 2,
March, 2,
April, none,
May, 2,
June, 1,
July, none,
August, 2,
September, 4,
October, 3,
November, 2,
December, 2,
Total, 24.

Year 1902:
January, 2 deaths from typhoid,
February, none,
3056 March, 2,
April, 1,
May, 1,
June, none,
July, none,
August, 2,
September, 5,

October, 4 deaths from typhoid.
November, none,
December, 1,
Total, 18.

That is all for St. Paul.

Q. Now did you go to Prairie due Chien?

A. I went to Prairie du Chien, but the records were incomplete, and they had only been taking them since the state law was passed, requiring the clerk of the city to make them, and he had only been making them for a short time.

Q. How large a place is it?

A. 3,500.

Q. Did you go to Dubuque.

A. Yes sir.

Q. Give us Dubupue?

A. January, 1893—

JUDGE SPRINGER: Is this Dubuque, Iowa?

A. Dubuque, Iowa, yes sir. Year 1893:

3057 January, deaths from typhoid fever, none,
February, 2,
March, none,
April, none,
May, 1,
June, none,
July, 1,
August, none,

December, none,
Total, 12.

Year 1903:
January, no deaths from typhoid fever,
February, 1,
March, 2,
Total, 3.

From there I went to Fort Madison. The records had only been kept a very short time and they commenced with the year 1900. I will not give each month when they had none. I will give each month when they had them. There are only four in the year, but if you gentlemen prefer, I can read them the other way.

Q. Just give what you have got there.

A. March 28th, 1900, 1 death from typhoid fever,
September 10, 1 death from typhoid fever,
September 30, 1 death from typhoid fever,
October 7th, 1 death.

Q. That is for what year?

3075 A. That is for the year 1900. In 1901 no deaths from typhoid fever.

Q. That is, there were none reported?

A. The law in Iowa is that all deaths must be reported to the city clerk, and he keeps a record of them, and it was from this record I got this. They have no deaths from typhoid fever.

Q. No record of any deaths, you mean?

A. Yes, that is the record showed none.

Q. That is what I was trying to bring out.

A. January 1st to March 31, 1903, no deaths from typhoid.

Q. Now that is all you found in your examination of the records at Fort Madison?

A. Yes, there had been no records kept before that time. From there I went to Keokuk, Iowa.

Year 1893:

January, no deaths from typhoid fever,

February,	none,
March,	none,
April,	none,

Year 1903:

January, one death from typhoid fever.

February, no deaths. That is all I have for 1903.

Q. Now you collected those figures from the—

A. Records myself, yes sir.

Q. You collected them directly from the records?

A. Yes sir.

Q. Now the next place you went was Quincy, was it?

A. No, Hannibal—no, it was Quincy, yes sir.

Q. You made the same character of examination at Quincy As you did at the other points?

A. Yes sir.

Q. Now you may state that.

A. 1893, January, one death from typhoid fever.

	February,	1,

Year 1902:

In January no deaths from typhoid fever,
February, none,
March, none,
April, none,
May, none,
June, none.

That is as far as the records at Hannibal show.

3093

CROSS-EXAMINATION,

By Judge Johns.

Q. In what one of these towns and how many of them did you find the records kept in regular form and tabulated?

A. You mean that were tabulated in printed form, or the records themselves tabulated?

Q. Their records themselves kept in tabulated form.

A. In all cities with the exception of Fort Madison, and I think Fort Madison was the only one,—they were kept under certain headings, running across the top of a large book. They gave the cause of death and age and the birth-place and death place, the burial place and all those sort of things. Is that what I understand you mean?

Q. Yes.

A. All with the exception of Fort Madison.

Q. That you found in all these stations you have named except Fort Madison?

A. Yes, except Fort Madison.

Q. In each one of those towns where you found these records, did they have persons, were there persons and clerks as custodians of those records?

A. Yes, in every case.

Q. In each case did the city or municipality have a seal in the custody of the clerk?

3094 A. I am unable to say that.

Q. You know that they had in some of those places?

A. In some places that I took in, two or three places, the records were kept by the City Clerk who had the seal of the city in charge. In other places, larger places, they were kept by the Health Commissioner. Only in one instance do I know of him having a seal.

Q. But in all these places except Fort Madison they were in the custody of some officer appointed for the purpose, keeping the records?

A. Yes sir.

CROSS-EXAMINATION,

By Judge Springer.

Q. Did you examine the records at Davenport, Iowa?

A. No sir.

Q. Or at Rock Island?

A. No sir.

Q. Isn't Rock Island a large city?

A. Yes sir.

Q. Why did you miss that place?

A. I was given a list of certain cities. I got them from that and I took only the ones from the list I was given.

Q. You did not examine the records at Galena, Illinois, 3095 either?

A. No sir.

Q. Did you take any account of the population of the various towns to which you have referred,—or cities?

A. Yes, in each instance I did; that is, the poulation at the time I took the records; that is the census of 1900.

Q. You didn't note the census of the previous years?

A. No sir, I did not.

Q. Have you those figures?

A. I have them in my desk at my office. I made some notations in my memorandum book and some on the copies themselves. Sometimes I would jot them down in my book and sometimes in another memoranda, and sometimes on the original memoranda that I made.

Q. Did you find upon these records any statement as to the number of cases of typhoid fever that were treated?

A. I found in one or two places, but they told me they were not accurate, that it depended on the physician. That they depended upon the physicians to report them and as a rule they were not sufficiently accurate to make any complete record from.

Q. Did the law require in these localities that deaths should all be recorded, and the cause of the death?

A. Yes sir.

3096 Q. And you took not only the typhoid death rate, but also the death rate of other diseases?

A. The total number, yes sir, in every instance. I have the figures here on that.

CROSS-EXAMINATION,

By Mr. Todd.

Q. All you have testified to, you got simply from the inspection of the records at the different places you have indicated?

A. Copying them from the record, yes sir.

Q. What place was there where the records showed the typhoid cases?

A. I recollect one instance,—Minneapolis.

Q. What other places?

A. I think that was the only one.

Q. And with whom did you have this conversation?

A. I think his name was P. M. Hall, Health Commissioner.

Q. And was this the same record that you took the statistics of death out of?

A. No sir.

Q. Did they have separate records for the cases of typhoid from the deaths from typhoid?

A. They were not separate records. He had them printed. The only record of typhoid cases, the only list of typhoid cases I saw was in the printed record, a printed report which 3097 was entirely separate. That is, it was a different table entirely from the table of typhoid deaths and total deaths.

Q. Was it from the printed report you got these figures you have testified to here in Minneapolis?

A. In Minneapolis, yes.

Q. Then you didn't go to the public records?

A. Yes I saw the public records and looked at them.

Q. Are the public records printed?

A. No sir. That is, they are in the Annual Report; the records are embodied in the report in the Health Department.

Q. Did you get your figures out of the annual report or from the public records themselves from which the annual report was made?

A. In this instance?

Q. I mean Minneapolis?

A. I got them from the printed annual reports.

Q. Did you compare the printed annual reports with the records in the Health Department of the place where these records are kept?

A. In the first year, and I was going over it in that way to see as far as I could, to ascertain whether it was accurate for one year. I was assured by the Health Commissioner they were.

Q. The question is did you make a comparison upon the
3098 printed report with the records themselves?

A. In 1893 I did, the other years not.

Q. Now were the public records that were consulted in regard to the cases of typhoid fever, kept in the same way the records were kept?

A. I didn't see any official record of them kept. The only table that I saw of them was in these printed annual reports.

CROSS-EXAMINATION,

By Judge Springer.

Q. You may state if you please, as to the cases of the cities to which you have referred. Have you the certificate of the clerk as to the correctness of these figures?

A. Yes sir. The City of Des Moines, Iowa; the City of Burlington, Iowa; the City of Minneapolis; the City of Dubuque.

Q. Just read one of those certificates so as to put it in the record.

A. (Reading) Burlington, Iowa, April 14th, 1903. State of Iowa, Des Moines County. I, Edward S. Johnson, Assistant City Clerk, City of Burlington, Iowa, on oath depose and say that the attached lists of deaths from typhoid fever and other causes is a true and correct copy from the original death records of the City of Burlington, Iowa, to the best of my knowledge and belief. Edward S. Johnson, Assistant Clerk. Subscribed and
3099 sworn to by said Edward S. Johnson, before me this 14th
day of April, 1903. F. P. Bulger, City Clerk." The one in Minneapolis differed a little from that. It is a certificate of the Health Commissioner, he being the custodian instead of the clerk.

LEE B. ENGLISH.

ADJOURNED until Saturday, May 9th, 1903, at 10:00 A. M,—Southern Hotel, St. Louis.

3100 Southern Hotel, St. Louis, Missouri. 10:00 A. M., Saturday, May 9th, 1903. Continuation pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

Whereupon an adjournment was taken until 10:00 A. M., Monday, May 11th, 1903, at Southern Hotel, St. Louis.

3101 Southern Hotel, St. Louis, Mo. 10:00 A. M., Monday, May 11th, 1903. Parties met pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

J. L. VAN ORNUM,

Re-called for further direct-examination by Mr. Woerner, testified as follows:—

Q. Professor, you have been sworn the time you testified before in this case, have you not?

A. Yes sir.

Q. Have you taken any samples of the water of the Mississippi and Illinois Rivers and tributaries recently for the purposes of examination?

A. I have taken samples of the waters of the Mississippi and Missouri Rivers for such examination.

Q. Now Professor, I wish you would state what you did and when, and the purpose?

A. On the 10th and 12th of April samples of water were taken at sections noted on this sheet (referring to map), one section being just above the confluence of the Missouri and Mississippi in the Mississippi river; another above the
3102 same confluence in the Missouri River; another section in the Mississippi River below the confluence of these two rivers, and a fourth one about 1,000 feet above the waterworks intake, above the St. Louis waterworks intake in the Mississippi River. These samples were taken for the purpose of sending to Mr. George C. Whipple, at Brooklyn for turbidity examination, and duplicates of each sample were retained in St. Louis, those duplicates being in the boxes in the room now. For distinguishing the samples there was tied at the time of taking, a tag about the neck of each bottle, on that tag being

a capital letter to distinguish the section as noted here (referring to map), section I being close to the intake, and section C also in the Mississippi River below the confluence of the Mississippi and Missouri, section M in the Mississippi above the mouth of the Missouri, and section B in the Missouri River above the confluence.

Q. Now professor, these were all cross-sections, were they, —these four?

A. These were all cross-sections, locations being kept on each cross-section from 1 t› the highest number. No. 1 always being towards the right bank of the river.

Q. You mean towards the Missouri shore?

A. Toward the Missouri shore.

Q. I wish you would state the number of cross-sections, respectively for each of these examinations—the number
3103 of samples taken from each cross-section?

A. The number of samples taken from each cross-section are indicated on this same sheet. There were three points on the section B in the Missouri River, and there was one sample taken at a ten foot depth, at each of these three points.

Q. How many times?

A. Once. No sample was taken but the once.

Q. One day you mean?

A. No, I mean there was one sample taken from each depth at each point, and that sample was large enough so that a duplicate bottle could be filled from the same sample. Above the mouth of the Missouri river in the Mississippi or at section M there are eight located points across the stream and one sample was taken at each of these points at a depth of ten feet below the surface; also at section C there are eight located points, and there were three samples taken at each of these points; one sample is marked after the section letter C, and after the point number 1, 2 or whatever it may be. The small "a" designates six inches below the surface, the small "b" means in every case ten feet below the surface and the small "c" on the tag means 30 feet below the surface (which was the length of the line) or else the bottom, if it was encountered at a less depth than 30 feet, and practically the same facts should govern the section I, which is above, St. Louis

3104 waterworks intake, where there are, however, twelve located points with three samples taken at each point, unless the bottom was encountered at the ten foot level or sooner, which was the case, I believe, in three instances, but in every case the small letter "a" on the tag following the section letter and the location number or figure (the small letter "a") indicates six inches below surface as the depth at which the sample was taken, "b" indicates ten feet and "c" either bottom or 30 feet if the bottom was deeper than 30 feet.

Q. Now what is the method of taking the sample from the river?

A. The sample was taken with an apparatus sent by Mr. Whipple which consisted of a stand in which a bottle was placed. This stand was weighted so as to cause the bottle and all to sink. There was a cord fastened to the stand by which it was lowered to the required depth, and there was also a spring connection with a short cord connection to the cork so that by a slight jerk the cork could be pulled from the neck of the bottle after the bottle was lowered to the required distance.

Q. Permitting the water to get into it?

A. Permitting the water to go into it.

Q. Now what was done with these bottles after they were brought to the surface; what did you do with them?

A. Sampling the bottle, after it was brought to the surface—was done by first introducing a thermometer immediately in the bottle to get the temperatures, which are also noted

3105 on the tags. Then the water was immediately after shaken,if there was any sedimentation at all apparent,was poured, half of it or whatever was necessary, to fill one bottle, into a bottle like these here. Another half of it or thereabouts was poured into another bottle. Half of these bottles were sent to Brooklyn to Mr. Whipple, and the other half are here.

Q. This map that you have in your hand is a correct indication of these locations and the number of points from which samples were taken at each location, is it?

A. It is, yes sir.

Q. It shows the current or the direction of the river, of the flow of the respective rivers in so far as it may be indicated on the map?

A. Yes sir; it shows in short everything to connect the tags with each bottle, and with the exact position of each sample as it was taken.

Q. Well now, I will ask you what the red line upon that map along the thread of the stream indicates?

A. That red line as near as may be indicates what may be called the channel line or the deepest water throughout the length of the Mississippi River as shown on this sheet. In some cases it is not quite true, for instance, below the jetty
near the waterworks intake there is deeper water behind
3106 it than there is where a steamship could travel, but it is
the deep water, and in general, practically the route that a steamship would follow,—(of deep draught) in trying to find the deepest water for navigation purposes.

Q. And that varies from one side to another in accordance with the windings and meanderings of the stream, doesn't it?

A. Yes sir.

MR. WOERNER: We will offer this map in evidence.

Said map received in evidence and marked Complainant's Exhibit 44.

MR. TODD: Is this the same map that you testified to the other day?

A. It is the identical print, yes sir.

MR. TODD: I object to the introduction of the map, in regard to what the map itself indicates, on the ground that it is not a correct condition that exists in the Mississippi River today, as the map was made in 1880, and has been stated by the witness in the other examination as not being correct as of today.

THE WITNESS: That was the latest and most authentic map that is obtainable.

MR. TODD: And I object on the further ground that the red line indicating the channel is placed upon the map by the witness and there is not sufficient evidence in the record to justify that that is the channel today, as indicated by the red line.

3107 JUDGE SPRINGER: Was the red line now appearing
upon this map showing the channel of the river, put

there by you recently or was it put there by the government when this map was made, in 1880?

A. It was not put there by the government; it was put there in Mr. Whipple's office, as I understand, and I have examined it and believe it to be as near as may be the channel line of the river.

Q. You didn't state before what examination you have made for the purpose of ascertaining that. What did you make?

A. I simply compared the line with the depth of soundings indicated on each side, those soundings being government soundings.

Q. Then you base your line upon the government soundings of 1880,—1879 or 1880?

A. I am not sure of the date, but whatever date is given there is the date of the soundings on which I based that line.

Q. Then your ascertainment of the channel is based upon soundings marked upon this map at the time it was made by the government officials?

A. Yes sir.

JUDGE SPRINGER: We object to it as not showing the channel at the present time.

MR. TODD: I want to make a further objection. I object to the note that is placed on this map at the north- 3108 west corner, and signed J. L. Van Ornum, as being no part of the map.

CROSS-EXAMINATION,

By Judge Johns.

Q. Under whose direction were these samples taken?

A. Under mine.

Q. Who took the samples at Section B?

A. Well, there was a party, each doing his own part in the getting of those samples, all under my personal direction.

Q. Who were the persons taking samples at Section B?

A. I want to answer the question; I don't know quite how. There was one man letting down the sampling apparatus; there was another man ready with the thermometer; another man ready with the bottles, another man marking the tags. I was in the boat looking after everything and also supervising the location.

Q. In what kind of a boat were you?

A. I am not sure whether it was a gasoline or naphtha launch; it was a power launch.

Q. It was a steam launch, or naphtha launch?

A. Yes.

Q. Now were each of these samples at each of these sections taken from this same boat by this same party?

A. Yes sir.

3109 Q. Where were the first samples taken?

A. At Section I, near the intake.

Q. Then you proceeded up the river?

A. Yes sir.

Q. Were all these samples taken on the 11th of April?

A. None of them on the 11th. Part were taken on the 10th of April and part on the 12th (referring to notes).

Q. Take section I, for instance; what is the distance between the various stations numbered from 1 to 12?

A. Four hundred feet.

Q. What is the distance of section 1 from the Missouri shore—of Station I?

A. My recollection is, about 300 feet—I will soon see (referring to book) 300 feet from the Missouri shore.

Q. How was that distance ascertained?

A. By sextant angle taken between transit placed on shore, (which was there to indicate when the launch was on the cross line) and the intake tower.

Q. When you took samples at station 1, at Section I, for instance, was the boat anchored and stationary?

A. No sir.

Q. How many samples did you take at Station 1 in Section I?

A. Three.

Q. At what depth?

A. Six inches, ten feet and I am not positive whether the
3110 lowest was 30 feet now—the tag will show, either 30
feet or one foot above bottom.

Q. Were those samples taken from three separate stands at separate times, or from one stand arranged to hold three bottles?

A. Neither. The boat was propelled just above the section at practically the right position and allowed to slowly float down and just before reaching the section the sampling apparatus was lowered, and on reaching the section the cork was pulled and the bottle allowed to fill at one certain depth; then after the sample was poured into the bottles for further use the boat was propelled back to the same location again and the same sampling apparatus lowered to a different depth, so the samples were taken successively.

Q. And was that on each numbered station at each one of these sections?

A. Yes sir.

Q. Is this the identical map that you had in testifying the other day in regard to following the floats?

A. As far as the printed portion of it is concerned, it is.

MR. WOERNER: You don't mean it is the same map, but a similar map?

A. Yes, it is another one similar; it is not the same sheet of course.

3111 JUDGE JOHNS: But it is identically the same as to the print of it?

A. Yes sir.

Q. Will you tell me what is the direction of the flow of the current of the Mississippi River from the place on this map marked Section I to and above the line marked 38 degrees and 47 minutes, across the map?

A. The flow is in the opposite direction. It is from that line 38 degrees and 47 minutes towards section 1.

Q. What is the direction by the points of the compass?

A. In a general way, southward.

Q. Well, is it exactly south, west of south or east of south?

A. In general it is some west of south.

Q. Are these cross lines running lengthwise of this sheet exactly north and south?

A. They are supposed to be; they are intended to be.

Q. They are intended to be north and south?

A. Yes sir.

Q. What were the names of the persons engaged in this taking of samples, other than the yourself?

A. M. F. Levy, H. Schantl, E. Sessinghaus, Robert Schmidt, P. R. Goodwin, and then in some positions and at different times there were changes. The second day some of the men in some positions were not the same as on the first
3112 day. For instance, the second day there was an S. Jones.
That names, as far as I recollect, the men who were with me.

Q. And are they all residents of St. Louis?

A. Yes sir.

Q. When were these samples taken upon the first day, shipped to Mr. Whipple?

A. I was told and I left instructions for them to be shipped to Mr. Whipple the next day and was told that those instructions were carried out, on my return to the city.

Q. When were the samples, taken on the second day, shipped to Whipple?

A. They were delivered to the express company on the day after taking.

Q. Duplicate samples are here, are these bottles now in the room?

A. Yes sir.

Q. What was done with them?

A. They were stored in the chemical laboratory of Washington University.

Q. Are they now here in the room in the same conditon in which they were stored?

A. Yes sir.

Q. In whose custody and charge were they at the chemical laboratory of the City of St. Louis ?

A. Dr. Keiser's.

3113 Q. How many samples altogether, did you take?

A. Sixty-eight.

Q. And then divided each of the 68 into two samples?

A. Yes sir.

Q. At what sections were the samples first taken?

A. At section I, near the intake; then proceeding up the river to section M; these were all that could be taken that day.

Q. Is that section M across the Mississippi?

A. Yes sir.

Q. How far above the confluence of the Missouri is that?

A. Oh, about half a mile above the point of confluence.

Q. And the other sections at C and B were taken two days afterwards?

A. Yes sir.

Q. Is the place here on the left hand side of the river above the line 38 degrees 47 minutes, and to the left of the large island marked on the plat where the word "sand" is printed known as Chouteau's chute?

A. No sir, Chouteau's Slough is this, indicating on Exhibit 44, and these are called simply "the chutes," popularly, along the river.

Q. Was it at one of these places I have designated, where the word "sand" is, that you took out one of the floats and placed it back in the river, to which you testified the other day?

A. Somewhere along there. It was, I think about a 3114 half a mile to the northeast, as I recollect it.

Q. But that was to prevent the bottle from going down the chute at the left of the island, through which the line marked 38 degrees and 47 minutes runs?

A. To prevent that float—

Q. Going down that chute?

A. Yes sir.

Q. If the float had gone down that chute, it probably would never have gotten anywhere near the intake?

A. Probably not.

Q. What is the distance between the lines marked on this map as a square, one geographical mile. Has each one of these squares a reference to a square mile?

A. Yes sir. Exactly it refers to one minute of arc, which is approximately a geopraphical mile in latitude.

CROSS-EXAMINATION,

By Mr. Todd.

Q. Professor, was this map made at low or high stage of water?

A. According to the notes placed upon the sheet by the Mississippi River Commission, the stage of water was comparatively low, varying evidently from four feet above to ten feet above the low water stage.

Q. What was the stage of the Mississippi at the time you made or collected these samples?

3115 A. It was higher.

Q. How much higher?

A. I couldn't say precisely. My impression is that the stage of water was 15 and 20 feet above the low water stage. I can determine that if desired.

Q. Was the channel of the Mississippi which is indicated upon this map in red the channel of the Mississippi at the time you took the samples?

A. I could not definitely state. There was every appearance of it being approximately or fairly closely in the position shown there.

Q. What effect does high water have upon the channel of a river?

A. It changes the deepest portion if the river. The channel at high water is very often more or less different from the location of the channel at low water.

Q. How are the currents of a river affected by high water?

A. In general they are increased.

Q. As to direction?

A. They are not the same in certain places as far as direction is concerned.

Q. High water has a tendency to change the currents in a river, doesn't it?

A. It does, especially where the channel passes from one side of the river to the other. Where the channel is in
3116 concave banks, on a certain side of the river, due to that concavity, the channel at high water remains the same or practically the same, but where the channel must make a cross-

ing, that is, pass from one side to the other—from that concave bank to a concave bank on the other side—then the position or crossing of that channel is frequently more or less changed from low water to high water.

Q. Now, between sections C and I of stages of water that existed at the time this map was made, the channel is illustrated here by a red line in considerable of a curve?

A. Yes sir.

Q. At high water such as existed at the time you took these samples, would the direction of the curve correspond to the direction of the red line indicative of the channel?

A. In some points I think it would; in others probably not.

Q. Why would it in high water, follow that line of channel?

A. At a certain point here, for instance, in a concave bank, whether the river is high or low, there would be no difference essentially between the direction of the current or the position of the deepest water between the high and low water, but the point which is below section C between it and the concave bank I just described, I suspect there would be a different direction of the current and possibly a different deepest channel location at high water.

3117 Q. If the water in the Mississippi River at the point indicated upon the map nearest to 38 degrees and 48 minutes should be 18 feet above the conditions that existed at the time this map was made, wouldn't the water flow in the course of the least resistance and come down over that island?

A. There would be a portion of the water pass over the island.

Q. Wouldn't the greater portion of the water come down to the east of the channel?

A. Do you mean by channel that same red line?

Q. The same red line, if the water was up eighteen feet?

A. There would be more to the east than west of the red line in that same bend, yes.

Q. Then the red line which indicates the channel doesn't necessarily indicate the direction of the current at high stages of water, does it?

A. Not precisely, nor does it indicate an equal division or quantity on one side or the other necessarily, ever.

Q. The water flows in the course of the least resistance, doesn't it?

A. Yes sir.

Q. The higher the elevation of water the greater number of obstacles are submerged which retards its flow?

A. Yes sir.

Q. And when those obstacles are submerged the water flows right over them unimpeded?

3118 A. It flows over them, but the obstacles still have a greater or less influence.

Q. That is true, no doubt, but the water at that high stage flowing over them would not necessarily follow in the confines of this channel at the low water mark?

A. No sir.

Q. Now is there anything upon this map that indicates the direction of the currents at the stage of water that you found at the time you made your experiments?

A. Only in a general way.

Q. Is that general enough to establish a scientific fact in regard to the currents?

A. It depends upon the scientific fact that it is desired to establish.

Q. The direction of the current?

A. Certain scientific facts which depend on the direction of a current to a great extent, would be proved by the sheet as submitted. Others that require specific direction in each position (or other point in that river,) would not be established by it.

Q. Did you calculate a cross section of the river at the time you made these examinations, in order to ascertain the volume?

A. No sir.

3119 Q. And without making that calculation, is it possible to accurately determine the course of the current as affecting the great volume of water in the Mississippi at either of these points?

A. It would be possible to say the direction of the current without making a calculation for volume.

Q. As to volume?

A. Yes sir.

Q. In what way could that be ascertained, doctor, as to what direction the greater volume of the water passing down the Mississippi River, would pass a given cross-section?

A. I did not understand the question last asked to be involved in the question previous. It would be necessary to have a determination for volume by parts at each section, to determine just where the greater volume of the flow passes. The direction of the current at any point would be determined by observing floats and taking the direction of them at any point.

Q. Did you make any calculation of the rate of the current at any one of the twelve points where you took samples?

A. No sir.

Q. The rate of the current at these points would be necessary to know in order to figure the volume of water passing a given point, wouldn't it? 3120

A. Yes sir.

Q. And that you did not ascertain?

A. No sir.

Q. Does the surface current in any one place indicate the current beneath the surface or near the bottom?

A. In direction or strength?

Q. In direction?

A. They usually are practically the same; not necessarily so.

Q. At what point in the river does the current flow the most rapidly, the top or the bottom?

A. It is more rapid at the top than at the bottom.

Q. Is there any law applicable to the rate of current in water.

A. Only in a general way. Each river seems to have its own special law. There are variations between different rivers, in trying to express the relations of flow at different points, or depths.

Q. Is there any mathematical rule established that applies to the velocity of running waters between the top and bottom, other points being given?

MR. WOERNER: I object to the question on the ground that the whole field now gone into in this examination has been gone into before with this same witness by the same counsel.

3121 MR. TODD: I want to state that the line of my examination is based upon the introduction of this map, where the depth of the river has been indicated upon it, and the curve has been indicated, and it is for the purposes of ascertaining the effect of that red line upon this map that I made this examination.

THE WITNESS: There is a formula which is not necessarily constant,—of a different magnitude for different rivers. There is no formula that will apply strictly to different streams and give correct results. There is a different ratio that applies everywhere.

Q. Do you know, doctor, where the channel of the Mississippi River changes?

A. Yes sir.

Q. Do you know how often those changes take place?

A. No sir.

Q. It is a fact that in the Mississippi River the channel of today might not be the channel six months' hence, isn't it?

A. It is.

MR. JEFFRIES: I object to that as incompetent and immaterial.

MR. TODD: Do you know whether the channel indicated here by the red line on this map is the true channel of the Mississippi River today?

A. I don't know.

3122 Q. Have you any scientific knowledge on the subject?

A. Of what is the true channel today in the river?

Q. Yes?

A. No sir.

Q. All that you know about the channel of the river as pertaining to this map is gathered from the soundings indicated upon this map which appear here in small letters within the channel of the river, is it not?

A. Precisely.

Q. And as to whether or not that channel has changed from 1879 and 1880(I wish you would look at that map so as to see that I am accurate about it) you are not able to state?

A. In general, the channel as far as observation will indicate, is the same as shown there, but precisely whether it is true or not, I don't know.

Q. What do you mean by observation, doctor?

A. By riding up and down the river and noticing where the channel of the river is indicated.

Q. Is that possible, is it possible to ascertain the channel by ocular observation?

A. In a general way, it is, fairly closely.

Q. Is there any way specific enough to enable one to form an opinion?

A. An approximate opinion; not a precise opinion.

3123 Q. Well, that opinion should not be entitled to very much weight, should it?

A. It depends upon what is to be proved by it, sir.

Q. In proving the channel of the river?

A. Well, it depends upon what knowledge of that channel is desired for. For instance, if it is wanted for—

Q. Do you think then, it is sufficient to prove the channel of the river for the purposes of this case?

MR. JEFFRIES: Object to the question as argumentative.

THE WITNESS: I think (for the case that Mr. Whipple is here to follow with) it will be to show that channel shown there.

Q. If it is true, doctor, why did you refer to this map in establishing the channel and why didn't you establish the channel by occular observation for that purpose?

A. Because the soundings which are shown there are better evidence than simply ocular observation.

Q. You didn't see this river in 1889?

A. No sir. It was in 1889 when the soundings were made.

Q. You didn't see the river at that time?

A. No sir.

Q. And you have seen the river within the last two or three months?

A. Yes sir.

3124 Q. And by ocular observation you determined where the channel was?

A. By ocular observation, I say nothing indicated that the channel was noticeably different from the channel as indicated there.

Q. At the time you went up the channel did you have this map before you to observe or check up this map by ocular observation?

A. On the first trip up the river this spring, I had a map like that; not that identical sheet—

MR. WOERNER: Let him finish.

MR. TODD: I thought you had finished.

THE WITNESS: That's all.

MR. TODD: If I interrupt you doctor, on your examination indicate it. I don't intend to. When you went up the river and had the map did you make any investigation with a view to checking up the channel?

A. No, nothing instrumental.

Q. I mean ocular. We are talking about ocular observations now. I assume you got no instrumental.

A. I simply observed its direction, the swiftness of the current and the direction of it, and such general facts as that which would indicate or locate very plainly what I said,—that the channel is near the concave bank on that side and
3125 near the concave bank on this side. Now ocular observation wouldn't permit me to definitely know where that crossing occurs between parallels 38 degrees and 47 minutes and 38 degrees and 48 minutes, whether that crossing is precisely right or not or whether it might not vary a hundred feet or two hundred feet or perhaps three hundred feet from the position shown there, but as far as the channel is concerned, in the concave banks, I think there is little doubt but that anyone would know definitely that the channel was practically the same at high water as at low, and practically at the same distance from the banks as indicated.

Q. If this channel should be 700 feet east of the point indicated here in the concave banks would that serve the purpose for the channel, Professor Whipples' channel, which you indicated a few minutes ago?

A. Hardly.

Q. Were there any necessity for establishing a channel at the point indicated by this red line, in order to meet the requirments of the channel you have indicated that Professor Whipple wanted?

A. No sir, there was no necessity of establishing a channel at any points to meet any requirements. The channel was established for the purpose of interpreting, if there was any way, instead of showing certain effects upon certain results ot 3126 Mr. Whipple, and certain channel depths if such results were shown.

Q. The word "channel" of a river conveys a definite locality in regard to the river, doesn't it?

Q. It does, but it is not always used in the same sense.

Q. What is your idea, Professor, of the meaning of channel?

A. I am using channel today, as meaning entirely, the deepest portion of the cross-section.

Q. Assuming now the deepest portion of the cross-section as meaning that in reference to my question, when I use the word "channel," then the channel of the river does not depend upon any use for which that channel is to be employed, does it?

A. No sir.

Q. Now is it possible to ascertain the deepest point of a cross-section by occular demonstration?

A. No sir.

Q. And that is all the information outside of this map that you employed in order to ascertain the present channel in the Mississippi River?

A. That's all except my general knowledge of where channels are to be expected from the outlines of the banks; for instance, that the channel is closest to the concave bank almost invariably, practically invariably.

3127 Q. Is there a rule which will enable you to locate the channel in the river if you have got the equation of the curve of its banks?

A. At other points except the crossings I can locate such channel fairly closely. Not exactly.

Q. Now in this point indicated here which we will call the concave bank, is it possible if you know the equation of that curve to locate the channel?

A. Not precisely.

Q. Even approximately?

A. Approximately we could, because we know that the channel is on this side of the concave bank rather than on the opposite side of the stream, always.

Q. Doesn't that depend upon the volume of water in the stream?

A. Not to any considerable extent, not usually.

Q. Does it depend upon the rapidity of the current?

A. No sir.

Q. Did you figure out what the character of that curved bank was?

A. No sir.

Q. Do you say now, professor that the red line indicates the channel of the river at that point for the year 1903?

A. I say again that I don't know whether it does or not precisely, but I believe that it is a fairly good representation of the position of that channel as it exists now. 3128

Q. Upon what do you base that opinion, that it is a fairly good representation?

A. On the fact that as far as appearance is concerned, the general outline of the bank is the same as it was at the time that topography was taken, and upon the fact that the bank is still a concave bank. That something like the same concavity appears there and upon the fact that apparently the swiftest water is nearest to that bank, and on the fact that unless there are variations in the regimen of the river, which would probably be indicated to ocular demonstration, on the ground that no such violent change would occur as to really throw the channel noticeably different from its general location as indicated there.

Q. Did you make any observations as to the relative speed of the current at that point?

A. No instrumental observations, no sir.

Q. Could you make observations with the eye relatively?

A. Only in a very general way.

Q. Is that specific enough, or is that general observation specific enough to enable you to come to any kind of an accurate conclusion?

MR. WOERNER: Object to the question on the ground that it has been asked and answered a number of times.

3129 A. An approximate or pretty close estimate can be determined. for instance, at the stage of water that existed at the time of passing these several points of the river, there was driftwood floating in the river, and this so-called drift-wood concentrates in the channel as our river men know thoroughly and they have to look out for it when they are piloting steam ships. Further, that an indication on this point of other things of a similar character, for instance, where there is the swiftest water, and any breeze. If the breeze is up-stream at all, the waves are higher or deeper where the water is swifter. Further that the indication of this speedier current in this same concave bank and other things like that not very definite or precise, but which together give a pretty thorough impression and pretty thorough knowledge of where the deep water and swift current occur, or rather the swift current and consequently the deep water occur.

Q. Now, professor, at the St. Louis intake—will you indicate the point on this map for me please?

A. (Indicating point on map) here.

Q. How far east of the St. Louis intake is the red line indicated upon this map approximately?

A. Approximately 400 feet.

Q. Professor, at the west of the in-let tower indicated 3130 on this map, there is a dike. Does that dike project above the water?

A. No sir, only at points in extreme low water.

Q. How far was the crest of the river from the crest of the dike at the time you made or took these samples?

A. I cannot answer that exactly. My impression is that it is about 15 and 20 feet above the top of the dike.

Q. When these samples were taken and shipped, were they packed in ice?

A. No sir.

Q. Nothing was done with them except to ship them in the condition they were put in the bottles?

A. Yes sir, only to prevent breaking.

Q. That's what I mean?

A. Nothing except to prevent breakage and get them safely in Brooklyn.

RE-DIRECT-EXAMINATION, BY MR. WOERNER.

Q. What you have testified to with respect to taking the samples and the places, you know of your own knowledge by observation?

A. I do, yes sir.

Q. You were there and saw the whole thing?

3131 A. Yes sir.

Q. You also are able to say what the depth of the river was at the places indicated at these cross-sections, or rather where the current was at that place?

A. Only at such points as had a depth of less than 30 feet.

Q. Well the red line on the map corresponded so far as you are able to say with what you observed at those points?

MR. TODD: I object to the question as leading.

MR. WOERNER: As to the channel?

A. Yes sir.

Q. So far, therefore, as at the place where the red line occurs, the place where you made these cross-sections it does indicate the channel?

MR. TODD: I object to that on the ground that is is leading, and that counsel is testifying, not being under oath.

A. In the same general way that I believe it indicates the channel at other points. The length of the line was not enough to instrumentally determine those depths.

RE-CROSS-EXAMINATION, BY MR. TODD:

Q. Professor, at the time that you made the soundings did you have this map with you?

3132 A. No sir.

Q. Did you make any memoranda or note-book of the depth at which these soundings were taken?

A. Do you mean these samples?

Q. I mean the samples, yes.

A. Yes, they were all indicated on the tags on the bottles as noted in the note on the northwest corner (refering to the map)

Q. At section B in the Missouri River you took three samples, did you, across the river?

A. Yes sir.

Q. And how many samples at each place?

A. One.

Q. How deep did you take the samples at each place?

A. Ten feet.

Q. Did you take all the samples at a depth of ten feet?

A. Yes.

Q. Professor, will you explain to me if the river was 14 or 18 feet above its normal condition at the time these were taken, how you are able to state in answer to the question of Mr. Woerner that the depth of water you took corresponded to the depth indicated on this map?

MR. WOERNER: I object to the question on the ground that there was no such answer given or question asked.

3133 THE WITNESS: That is just what I was going to state.

MR. TODD: Will you explain to me what you intended to convey by your answer to the question in regard to the channel and your observations there?

A. My answer was intended to convey the idea that the same fact which led me to consider the red line as in general indicating the channel, in answer to your question, that I last gave, are the observations when we were taking these samples in the cross section.

Q. And have no reference then to the soundings indicated upon this map in regard to the locality of the channel, did it?

A. Do you mean by that the correctness of those depths as shown by my own samples?

Q. Your own soundings?

A. It had nothing to do with that.

Q. So then, as far as your soundings are concerned, or putting down the bottles for the purpose of getting the samples, that gave you no indication as to the channel by measurement, did it?

A. In point of fact it did not, because the depths (except in a few places of the river), were greater than the length of the water line.

Q. And you made no comparison between the depths of

your soundings, using the word in the sense of going down
3134 after the water to compare with the depth of soundings
indicated upon this map?

A. No sir.

CROSS-EXAMINATION BY JUDGE SPRINGER.

Q. Did I understand you to say that the object of taking these samples was for the purpose of determining the turbidity of the water at the different places where the samples were taken?

A. I believe I said so, yes; that is my recollection.

Q. Is that the only object for which they were to be used?

A. I am not positive about that. That was the main purpose?

Q. I understood that to be your statement. That is the reason why I regarded it for the special purpose and not the general analyses of the water in the river?

A. I have no definite knowledge of what use they were put to other than that. Or whether—

Q. If they were taken and should be used, for other purposes I should desire to ask some further questions of this witness, but at present I have no further questions to ask.

MR. WOERNER: That is not a part of his testimony, what was done with it.

MR. JEFFRIES: We will offer in evidence three boxes
as complainant's Exhibit No. 45, A, B, C, and to be re-
3135 ferred to hereafter as Van Ornum's Exhibits.

THE COMMISSIONER: I will mark them Complainant's Exhibit No. 45, A, B, C.

J. L. VAN ORNUM.

3136 GEORGE CHANDLER WHIPPLE,

called as a witness in behalf of the complainant, being first duly sworn by the Commissioner, was examined in chief by Mr. Woerner and testified as follows:

Q. State your name in full?

A. George Chandler Whipple.

Q. Where do you reside?

A. In Brooklyn, New York.

Q. What is your occupation?

A. My official title is that of biologist and director of Mount Prospect Laboratory of the department of water supply, gas and electricity of the city of New York.

Q. How long have you been in that position?

A. Since 1897, except that when I began at that time I was employed by the city of Brooklyn, and since then there has been a consolidation with New York City, but the position has been practically unchanged.

Q. State what education you have had and what positions you have held with respect to science on the subject of waters and bacteriology and other scientific positions you may have held?

A. Well, I graduated from the Massachusetts Institute of Technology in 1889 in a course of civil engineering. During the summer vacation previous to my graduation I was inspector of tenement houses in the City of Boston; after graduation I was employed for several months by Mr. Desmond Fitzgerald, Superintendent of the Boston Waterworks, on some experiments upon the filtration of water through a sponge. In the fall of that year a biological laboratory was established by the Boston Water Department and I was placed in charge of that work with the title of biologist. The work of the laboratory consisted in keeping a supervision of all the sources of supply of the city of Boston, and in addition to the inspection of the sources we made microscopical examinations, physical examinations, bacteriological examinations and occasional chemical analyses of the various sources of supplies. In connection with that work I had to make tests of the sewage disposal system at South Framingham, which was located upon the watershed, also the sewage disposal system of Natick, Massachusetts. I also made frequent tests of the sand filter at Pegan Brook in Natick, Massachusetts. 3137

I also made an inspection trip which covered all of the large water supplies of Massachusetts for the purpose of comparing the waters of the City of Boston with those of the cities tested. I also made frequent trips to the Lawrence experimental station, conducted by the Massachusetts State Board of Health for

the purpose of observing their experiments. For three years an experimental filter plant was carried on near our
3138 laboratory and I had charge of all the biological examinations made in connection with these experiments. During the eight years with which I was connected with that laboratory, I made numerous experiments on the growth of microscopic organisms and upon the temperatures of large bodies of water, especially in regard to the so-called stagnation phenomenon.

In that connection I assisted in designing an instrument called the thermophone, for obtaining the temperature of water at the bottom of a reservoir. From 1893 to 1896 I also had charge of a biological laboratory under the direction of the waterworks of Lynn, Massachussets, where similar tests were made.

In 1896 I spent four months with Professor Albert R. Leeds at Hoboken, New Jersey and assisted him in studying the character of the water at Brooklyn, New York, which at that time was affected with a bad odor.

In 1897 I established the laboratory known as the Mount Prospect laboratory in connection with the Brooklyn Water Department. I had charge of its equipment and planned the work. The scope of this laboratory was extended after the annexation of Brooklyn to the City of New York, and the analyses of water which included, chemical, physical, microscopical and bacteriological tests were extended to cover the borough of Queens as well as the borough of Brooklyn. In January, the 1st of the present year, the scope of the laboratory was still
3139 further extended and now covers all of the water supplies of New York City. In connection with my work I have occasion to visit all the watersheds and keep a lookout on the presence of typhoid fever in the city and in general to watch the sanitary condition of the water supply in connection with my work. I have had to investigate a number of local epidemics of typhoid fever.

Early in the present year a commission was appointed to study the future supply of water for New York City, this Commission being known as The Commission on Additional Water Supply. All sanitary investigations involved in that problem have been placed in my hands, and we now have a temporary laboratory at Poughkeepsie, New York and at Katonah, New York. We are making a careful study of all sources of water supply that are available for the city of New York, and this includes practically all the waters of the eastern part of New York State. We are making special studies of all streams which drain into the Hudson River, as well as of the Hudson River itself. In all we have about 50 men employed in this investigation at the present time.

In connection with my regular work in the laboratory I have recently made a test of the electro zone process of purifying water and am now preparing designs for a sand filter designed to filter 15,000,000 gallons of water on the Croton water-
3140 shed.

MR. TODD: Per day?

A. 15,000,000 gallons of water per day. In connection with the work of additional supply. I am now making a test of the sand filter at Poughkeepsie, New York and am carrying on experiments of the sedimentation of water of the Hudson river at Poughkeepsie, and am studying the question of how far the sea water runs up the Hudson River under different conditions. In addition to the regular work connected with my position, I have a considerable private practice as a sanitary expert and during the past six years have examined samples of water from nearly every state east of the Mississippi River, also some from Cuba and from Egypt and from India. I have had a long series of samples from Little Falls, New Jersey, Watertown, New York, Oswego, New York, Birmingham, Alabama, from the Red River, Louisiana, from the Delaware River at Trenton, from York, Pennsylvania, from the Susquehannah River at Binghampton, New York and the Wabash at Vincennes, Indiana, and elsewhere.

I have also made a report upon the electro-lytic method of water purification for the United States War Department.

I am also consulting chemist for the water department in Binghampton, New York and have recently completed a test of a mechanical filter which filters water at the rate of 6,000,-
3141 000 per day, and have had practical charge of the operation of that filter during the past year.

I have recently investigated an epidemic of typhoid fever at Waterville, Maine, where there were more than 250 cases, and this investigation was also extended to the towns of Fairfield, Maine, Winslow, Maine, and Benton, Maine.

MR. WOERNER: What is the population of Fairfield, Maine?

A. As I recollect it, it is about 1,000, but the population of Waterville is 10,000.

I am also employed as Sanitary Expert for the Kennebec water district.

I have published some sixty or seventy scientific pamphlets on various subjects relating to water and sanitary matters and am the author of a book on the miscroscopy of drinking water.

Q. What is the full title of that book?

A. That is the full title,—the Microscopy of Drinking Water.

Q. Is your name identified with that?

A. Yes, the Microscopy of Drinking Water by George Chandler Whipple, published by John Wiley & Sons in 1899 I think it was.

Q. Let me interrupt you there a moment, professor. Without laying you open to the criticism of immodesty, I want to ask you if that book is not considered one of the most recent and best authorities on that subject?

3142 A. I have frequently seen it referred to as such, and it is used as a text-book in the Institute of Technology of Boston, but the University of Minnesota—

MR. TODD: You will admit it is such without argument.

A. Yes, I suppose so. I am also engaged in the preparation of a work on hygienic analysis and another on water supply in general.

JUDGE SPRINGER: Not published?

A. No sir, not published. I have made a good many experiments associated with the methods of water analyses and devised the so-called silica standard for the measurement of the turbidity of water which has been practically accepted by the United States Geological survey.

I also devised the scheme for tabulating the results of odor determinations which has also been generally accepted, or which was accepted by the American Public Health Association.

I am a member of the American Society of Civil Engineers and the American Chemical Society, the American Microscopical Society and the Society of American Bacteriologists, and the American Public Health Association of which I am secretary of the laboratory section, also the Society of Chemical Industry.

3143 Of the American Limnological Commission, and I am a fellow in the Royal Microscopical Society of London.

I am also secretary of the Committee on Standard Methods of Water Analyses of the American Public Health Association.

Perhaps that is enough.

MR. WOERNER: Well now professor, engaging in these various matters to which you have testified, and having kept abreast of your profession, especially in the writing of those works, were you required to study all the scientific facts and acquire all the scientific knowledge relating to diseases bred and borne along by water and the various ways of avoiding the same and in thoroughly familiarizing yourself with the various microscopical organisms in water and of matters relating to the sanitary conditions of water?

MR. TODD: I object to the question as leading?

A. Yes. The nature of my official work has required that I keep myself informed upon the matters which you mentioned.

Q. And have you done so or not?

A. Yes, to the best of my ability.

ADJOURNED until 2:00 P. M. same day May 11, 1903.

3144 Southern Hotel, St. Louis, Missouri. 2:00 P. M., Monday, May 11th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE,

Resumed the stand for further direct-examination by Mr. Woerner, and testified as follows:

Q. Professor Whipple, have you had any occasion to make microscopic examinations of samples of the waters of the Illinois, Mississippi and Missouri Rivers?

A. Yes sir.

Q. And if so, state when?

A. In October and November, 1901 I made microscopic examinations from, I think it was 136 samples taken—some from Lake Michigan, some from the Chicago Drainage Canal, some from the Illinois River, some from the tributaries of the Illinois; some from the Mississippi River above Grafton, some from the Mississippi River at Alton; some from the Missouri River at Bellefontaine; some from the Mississippi River at the chain of rocks, and at the Illinois shore opposite the chain of rocks; some from the settling basins of the St. Louis waterworks.

Q. Now from whom and how did you obtain these samples?

3145 A. I understood that these samples were taken by different collectors under the direction of Dr. Ravold, and it is my impression that he has already testified to sending these samples to me, some of them were taken by Dr. Ravold's brother, and I understand that he has testified to sending them to me. I have a list giving the names of the different samples and the name of the collector, which I can read if necessary.

Q. Well, where did you receive the samples?

A. When?

Q. Where?

A. At mount Prospect laboratory in Brooklyn.

Q. How were they sent to you?

A. They came in two-quart bottles.

Q. I mean what was the method of transportation, if you know?

A. By express.

Q. Were these bottles labeled or marked in any way?

A. Yes, they were marked so as to identify their source; they were marked with the name of the collector and the date and hour at which he collected them, the temperature of the sample was also recorded as well as the temperature of the air at the time at which the sample was taken.

Q. In what condition were these samples received by you?

A. They seemed to be in good condition for the purpose of microscopic examination. The bottles came sealed and in every case the seal was unbroken.

3146 MR. TODD: I move to strike out that part of the answer where he employs the words "good condition."

MR. WOERNER: Well, state what you mean by the term "good condition," professor?

A. Well, I mean that the bottle was unbroken, and the sample was received apparently in the condition in which it was packed.

Q. Did you make any examination of these samples?

A. Yes sir, I examined them—all of them microscopically and of some of them I determined the turbidity and color.

Q. State for what purpose you examined them?

A. I examined them microscopically in order to determine the number and character of the microscopic organisms present, and I examined some of them for turbidity in order to find the amount of suspended matter present.

Q. Now before going into the results of your examination, professor, I want to ask you what are microscopic organisms and how do they differ from bacteria?

A. Strictly speaking, all very minute organisms my be called microscopic organisms, but all water analysts have come to understand by the term "microscopic organisms" those minute forms of life which are too small to be readily identified without the use of a miscroscope, but which are large enough so that they do not need to be studied by artificial cultures as we study 3147 bacteria. For example, the microscopic organisms belong some of them, to the plant kingdom and some of them to the animal kingdom, although among these low forms of life it is somewhat difficult to draw the distinction between animals and plants.

Q. Bacteria, are they all of vegetable—are they vegetable matter?

A. Bacteria can be said to belong to the plant kingdom, or vegetable kingdom is a better term.

Q. Now, what changes, if any, would be likely to occur with respect to these organisms in the water which you received, while it was in transit?

A. Well, some of the organisms found might die out during the period of transit; others of them might possibly develop during transit, while others still would probably remain unchanged. They would not increase in number and neither would they disintegrate to such an extent as to be unrecognizable.

Q. Now, professor, can you state what the result of your examination and investigation was?

A. Well, do I understand you would like to have the detailed results?

Q. Yes.

A. I have tabulated the results of the observations and the microscopical examinations which I made, and I have with me these tables which contain the results.

3148 Q. Well, can you refresh your memory by looking at those tables?

A. (Witness refers to tables). I have here a table——

MR. JEFFRIES: Are those duplicates?

A. Duplicates, yes, sir. I have here a table which I have marked table zero, which gives the results of the microscopic examinations made from samples of water said to be collected from Lake Michigan, five of these samples being labeled as coming from the Lake View crib, three as coming from the Carter Harrison crib and two as coming from the Four Mile crib. At the top of the table is a line giving the number of the sample, and I may explain that the samples as they were received, were given a serial number, and that these numbers in this line refer to those serial numbers. Beneath the line giving the number of the sample, is a line giving the locality from which the sample was collected, and beneath that a line giving the depth in feet at which the samples were collected, and beneath that a line giving the date of collection. Then in vertical columns I have placed at the left the name of the group of organisms found in the sample. In the second vertical column are the names of the genera found, and in the succeeding columns are the numbers of those genera which were found expressed in terms of standard units of organisms per cubic centimeter. Shall I go on and explain this further?

3149 JUDGE SPRINGER: You might explain the bottom line there?

A. Near the bottom there are two lines, one giving the total microscopic organisms, which numbers are the summation of the numbers given in the vertical columns, and then the last line giving the amount of amorphous matter which represents the amount of matter without form, simply, you might say, dirt, almost. Matter which is not recognizable as an organism; also expressed in terms of standard units per cubic centimeter. And I may say that this term "standard unit per cubic centimeter" is designed to show the relative bulk of these organisms present. In some cases one standard unit corresponds with one organism. A standard unit as it is used is a unit of superficial area equal to 400 square microns, one micron being equal to 1-1000 of a millimeter. The advantage of using this unit of a standard unit instead of numbers is that the organisms differ in size and it is our intention in these analyses to express as far as possible the relative bulk of the different organisms present, in order that one may be compared with another.

MR. WOERNER: Professor, in all of the tables which you are about to testify to, you use the same standard and measure, do you not?

A. Precisely.

Q. So that this applies to all of your tables?

3150 A. Yes, sir.

Q. Now, Professor, what do the results of your investigation as appearing upon this tabulated statement to which you have referred, indicate to your mind?

A. Well, I can answer your question by giving you the general results as shown by these figures.

Q. We want the general results first.

A. The most abundant organisms present in Lake Michigan during the period covered by these examinations were synedra and tabellaria, which belong to the plant kingdom, known as the diatomyceae, or to use a shorter expression, they are known as diatomes. There were other diatomes which were constantly present, namely, asterionella,cyclotella and nitzschia, fragilaria, and a few others which were noted on most of the occasions when samples were collected, namely, melosira and stephanodiscus. Other diatomes were found occasionally. In the group known as the chlorophyceae or to use a more popular expression, the green algae, the most constant form present was dictyosphaerium, and a number of other green algae were present at times. Among the cyanophyceas the most constant form

was the coelosphaerium. I might say that the popular name for this class of cyanophyceae is blue-green algae, as distinguished from the green algae in the class previously mentioned. The microcyztis and oscillaria and aphanizomonon were present on many occasions. The protozoa, which may be in gen-
3151 eral considered as belonging to the animal kingdom—
were not as abundant as the plant forms above enumerated. The most constant form among the protozoa was dinobryon, which was present on nearly every occasion. The other forms were less numerous. The rotifera, or the rotiferas which also belong to the animal kingdom were practically absent during the period covered by the examinations. The total numbers of microscopic organisms expressed in the usual forms of standard units per cubic centimeter varied from 576 to 1656. It will be noticed by a comparison of samples Nos. 32 and 33, the first two columns—the first of which was collected at a depth of five feet at the Lake View crib, and the second at a depth of 25 feet—it will be noticed that the organisms were somewhat more abundant at the surface in the former sample than in the latter and this is in accordance with what is generally observed in lakes, that microscopic organisms of these classes are generally more abundant near the surface than at greater depths. Speaking broadly, there is a general agreement among the samples, examinations of which are recorded on this sheet, showing that during this period these organisms were fairly well distributed through the lake at the points covered by the samples.

Q. This sheet relates entirely to Lake Michigan water, does it?

A. Yes, sir.

3152 Q. That is the one marked zero?

A. Yes, sir.

Q. Now take up the next one, doctor?

A. The next sheet?

Q. Yes?

A. Shall I go ahead and describe the second sheet as I did the first?

JUDGE SPRINGER: I think you had better give each sheet a number so that you can identify them.

MR. JEFFRIES: We want you to give the general description of the sheet as you have it.

MR. WOERNER: First describe the sheet and state what it is?

A. This sheet that I now present is known as plate No. 1, and it contains the results of examinations of samples said to be collected from the Chicago Drainage Canal, the first four of which were marked Paulina Street and the last six marked Bear Trap Dam, Lockport. The general arrangement of the sheet is similar to that of sheet number zero.

Q. Well, do you want to go on and explain that now or later on?

A. Just as you wish.

Q. Well, go on and show what the sheet indicates. These sheets, I understand, were made by yourself, were they not?

A. Those sheets were personally prepared and copied 3153 from my original records. It will be seen from the results shown upon this plate No. 1, that synedra and tabellaria were constantly present in the waters in the samples, and that asterionella and cyclotella and nitzschia were likewise constantly present; also that the melosira were present on a number of occasions; that the coelospharium among the blue-green algae was present on most of the occasions, likewise certain forms of organisms not so commonly present in Lake Michigan, namely, clandothrix, which belongs to the class termed schizomycetes and fungi and monas, which belongs to the group of protozoa. Vorticella of the same group were somewhat more constantly present in these samples than in those on the first sheet. The total numbers of organisms varied from 644 to 2750 standard units per cubic centimeter. The amorphous matter was more abundant than in the samples collected from Lake Michigan.

Q. Now, that is the sheet referring to samples taken in the drainage canal, is it?

A. Yes, sir; the Chicago Drainage Canal, except that I might say that I understand that the samples at Paulina street were taken really in the Chicago River before the drainage canal begins.

Q. Yes, and the others were taken from the drainage canal itself?

A. Yes, the others were taken at the Bear Trap Dam at Lockport.

3154 Q. Now, is that all that you wish to say about that?

A. Yes, sir.

Q. Now, professor, passing down the river, what is the next station the samples of which you examined and investigated?

A. The Desplaines river at Lockport, Illinois. This is plate No. 2, and contains results of six samples said to be collected from the Desplaines river at Lockport, Illinois, above the entrance of the Chicago Drainage Canal. It will be seen from this sheet that the organisms in general were much less numerous than in Lake Michigan or in the Chicago Drainage Canal. On one occasion, namely, on November 26th, 1520 cyclotella were found, but with this exception no organisms were abundant. The total numbers of organisms varied from 24 to 126, excepting on the date mentioned, when there were 2316. I should say on that same date that asterionella were present to the extent of 680 standard units per cubic centimeter.

Q. Now, with respect to all of these sheets, professor, the number of these organisms that were found are correctly stated by the sheet although you are not reading them—

A. Yes, sir.

Q. At this time; they are correctly stated on the sheet opposite the respective names?

A. Yes, sir.

Q. What is the next point from which you examined the samples?

3155 A. Plate No. 3 contains the results of examinations from the various tributaries of the Illinois river, and these tributaries are enumerated at the top of the page in the vertical columns. There was one sample from each tributary except in the case of the Sangamon river where there were six. It will be seen that these tributaries vary considerably in the number of microscopic organisms found. For instance, the total numbers of the microscopic organisms varied from 20 to 11,296. It will be noticed that the synedra and tabellaria, which were so commonly present in the Lake Michigan water and in the water from the Chicago Drainage Canal are here only sparingly found. The cyclotella were not found in a good many samples from a good many of the tributaries, but were found in large numbers, I may say in extraordinarily large numbers in the samples from

Crane Creek, No. 110, and in large numbers, though smaller than Crane Creek, in Apple Creek and McKee Creek, and the Sangamon River and the Spoon River. There were none of the chlorophyceae present in large numbers, nor the cyanophyceae or the schizomycetes or fungi. The anthophysa, one of the protozoa was quite commonly present in the tributaries as well as the monas and the trachelomonas. Trachelocerea was present frequently in the Sangamon river and in one or two other places.

Q. Now, that is the chart refering to the samples taken from the tributaries, and numbered?

3156 A. Plate 3.

Q. Now, professor, what is the next point from which you examined samples?

A. Plate No. 4, samples received from the Illinois river three miles above Peoria. This sheet represents the results of six examinations. The most important facts to be noted are the presence of synedra and tabellaria, cyclotella, dictyesphaerium and coelosphaerium. The total numbers of organisms varied from 300 to 816 standard units per cubic centimeter.

Q. This table like the others shows the number of these organisms, respectively, of each kind, together with the dates upon which you found them?

A. Yes, sir; the dates being taken from the tags which accompanied the samples.

Q. In case no organisms of any of these particular genus appear, did you incorporate the name in the table together with the statement that there were none of such, or did you omit the name altogether?

A. I omitted the name from the table.

Q. Now, professor, passing on to the next point down the river from what point did you next examine samples?

A. From the Illinois river at Beardstown.

Q. Identify the chart for that?

A. These results being recorded on plate No. 5, and this 3157 sheet gives the results of five examinations at this point. It will be seen from this sheet that the most prominent organisms were cyclotella, synedra, tabellaria, anthrophysa and monas. The total number of microscopic organisms varied from 350 to 3376 standard units per cubic centimeter.

Q. Now, will you please pass on to the next point?

A. And this is plate No. 6, which represents the results of samples collected from the Illinois river at Grafton, Illinois, there being seven such analyses reported. It will be seen from this sheet that the most prominent organism was the cyclotella, which was constantly present, but which varied in numbers from 4 to 23,200 standard units per cubic centimeter. Synedra and tabellaria were also prominent, as was also dictyosphaerium and scenedesmus. The total numbers of organisms varied from 54 to 23,876 standard units per cubic centimeter.

Plate No. 7 represents the results of seven examinations from samples from the Mississippi river collected above Grafton.

Q. How far above Grafton—I see the prior one was at Grafton; is that right?

A. I can tell by consulting my book.

Q. Oh, this is Mississippi river above Grafton now?

A. Yes, this is Mississippi river above Grafton. Do you want me to locate it more definitely?

3158 Q. No, that will do. The distinction is that the prior chart illustrated samples taken in the Illinois river at Grafton, and this is one in the Mississippi River above Grafton.

A. The distinction being that the samples in the Illinois river were taken from the Illinois river above its junction with the Mississippi and the Mississippi samples were taken above the point where the Illinois river enters.

It will be seen from plate No. 7, that the two most prominent organisms present were melosira and cyclotella. Asterionella were also present on most of the occasions and stephanodiscus were present on all occasions. The navicula were also present in five out of seven samples; the protococcus was present in all samples but one, and in the sample collected October 23rd scenedesmus was present to the extent of 1,000 standard units per cubic centimeter. On the same date clathrocystis was present to the extent of 1800 standard units per cubic centimeter. Microcystis was present in five out of seven samples and actinoprys was present in all of the samples. Monas was present in five out of the seven samples. The total numbers of organisms varied from 2000 to 15,380 standard units per cubic centimeter.

Q. What is the next point?

A. Plate No. 8 contains the results of six samples collected from the Mississippi river at Alton, Illinois. It will be 3159 seen that melosira and cyclotella were the most prominent organisms. They were present on all occasions in comparatively large numbers. Stephanodiscus was also present on all occasions. Asterionella was present in four out of the six samples. Navicula was present in four out of the six samples; synedra was present in three out of six samples, and tabellaria in two out of the six samples. Dictyosphaerium was present in five out of the six samples and so also was protococcus, while scenedesmus was present in all of the samples. Actinophrys was present in four out of six samples, and monas was present in five out of six samples. The total numbers of organisms varied from 2560 to 12,036 standard units per cubic centimeter.

JUDGE SPRINGER: Does it state at the top of that where it was taken, at Alton, whether it was above the city or below the city? Does it state on that sheet?

A. It doesn't state on that sheet. The samples sent to me were said to be taken from the Mississippi river at Alton. I learned from Dr. Ravold that they were taken from midstream, I think, a short distance above the city. I think that Dr. Ravold has put in evidence the location of samples that he sent to me. I understand so.

MR. WOERNER: Go on to the next point?

A. Plate No. 9 shows the results of five examinations of 3160 samples collected from the Missouri River at Fort Bellefontaine. It will be seen that the organisms in the Missouri river were far less numerous than in the Mississippi river. Cyclotella was found in small numbers on two occasions. Melosira in small numbers on three occasions. Stephanodiscus on one occasion. Asterionella and tabellaria which were observed in Lake Michigan and in the samples from the Illinois river and the Mississippi river at Alton were not found at this point. Synedra were found.

MR. JEFFRIES: Were they found in the Mississippi river above Grafton?

A. Well, I think some of those that I have enumerated were, but I think perhaps not all. Synedra were found in small numbers on three occasions. Protococcus was found in four out of five samples and monas in four out of five samples. The total numbers of organisms varied from 80 to 190 standard units per cubic centimeter.

Q. MR. WOERNER: Now, what was the next point?

A. Table No. 10 represents the results of examinations of seven samples collected from the Mississippi river—

Q. From the Mississippi river?

A. From the Mississippi river at a point near the Illinois shore opposite the intake.

3161 It will be seen from this table that the most prominent organisms were the melosira and cyclotella and stephanodiscus, these organisms being present in all of the samples. Asterionella were found in four out of the seven samples; synedra were found in five out of seven samples and tabellaria in four out of the seven samples. Nitzschia in five out of the seven samples and navicula in four out of the seven samples. Dictyosphaerium was found in four out of the seven samples. Pediastrum in six out of the seven samples. Protococcus in six out of the seven samples. Scenedesmus in six out of the seven samples,—actinophrys in five out of the seven samples, and monas in five out of the seven samples —

MR. TODD: Isn't that four?

A. Monas in four out of the seven samples. I read a mark which was apparently in the number, and which is not part of the table.

MR. WOERNER: Monas should be four instead of five?

A. Yes, monas should be four. There is a little bit of a thread that looked like "1." The total number of organisms varied from 1588 to 8344 standard units per cubic centimeter.

Q. What is the next point?

A. Plate No. 11 represents the results of seven examinations of samples collected at the Intake of the waterworks at the Chain of Rocks.

3162 It will be seen from this table that the most prominent organisms were melosira, which was present on all occasions; cyclotella which was present on five out of the seven samples; stephanodiscus was present in six out of the seven samples; asterionella present in three out of the seven samples; protococcus present in five out of the seven samples and scenedesmus present in four out of the seven samples. Synedra were present in three out of the seven samples, and the total numbers of microscopic organisms varied from 310 to 1880, standard units per cubic centimeter.

Q. Now, you made no others of the Mississippi river, did you?

A. No, sir—I beg your pardon; I made two other series, shown in plates 13 and 14.

Q. But they were not in the Mississippi, were they?

A. They were in the Mississippi river, both of them, and represented cross-sections.

Q. Well, just keep the order in which you made the examinations and pass on to the next?

A. To the next serial number?

Q. Yes?

A. Table No. 12 represents the results of two examinations from samples collected in the settling basins of the St. Louis Waterworks at the Chain of Rocks.

It will be seen that cyclotella were present in both of these
samples; asterionella were present in both of the samples;
3163 tabellaria was present in one sample; stephanodiscus was
present in one sample; dictyosphaerium present in both
and protococcus present in both samples. The total number of organisms in one sample being 380 and in the other 480 standard units per cubic centimeter.

Q. Is that the last one?

A. Plate No. 13 represents the results of 12 samples collected from the Mississippi river in a cross-section just above Alton on November 12th, 1901. The result showed the presence of melosira, stephanodiscus and dictyosphaerium in all of the samples; asterionella was present in all but one; cyclotella in all but one; synedra were not present in the first five samples, but were present in the remaining seven. Tabellaria was not present in the first four. It was present in the next two. It was absent from the next two and was present in the last four.

MR. TODD: Doctor, were these samples taken at the same time right across the river?

A. I understand that the information in regard to the collection of these samples has already been put in evidence by Dr. Ravold and I understand from him that they were taken on the same day, on November 12th, at equal distances apart and that the numbers ran from 1 to 12, beginning with the Mis-

3164 souri shore and running towards the Illinois shore. That is, the left hand side of the sheet represents the Missouri shore and the right hand side of the sheet represents the Illinois shore.

The protococcus was present in all of the samples but two; scenedesmus in all of the samples but one. I may have stated that. Actinophrys was present in all of the samples but two, namely, Nos. 2 and 12. The other organisms are of lesser importance. Perhaps I need not enumerate them at all.

MR. WOERNER: But they are all given on the sheets?

A. They are all given on the sheets. I might say that the total numbers varied from 1464 in sample No. 12 to 3408 in sample No. 1.

MR. TODD: 12 is near the Illinois shore, isn't it?

A. Yes, sir; and I stated in the foot-note the fact which you asked, that the samples were taken at approximately equal distances across the river. The cross-section number, that is the number of the sample in the cross-section as distinguished in the serial number given in the first line is at the Missouri shore and cross-section No. 12, if I may be permitted the correction there, that line to 12 is at the Illinois shore.

Plate No. 14 gives the results of microscopic examinations of samples collected from the Mississippi River at a cross-section just above the Chain of Rocks, on November 10th, 1901. The arrangement of these samples in the cross-sections from 1 to 11 being the same as in the previous sheet, namely,
3165 from the Missouri shore towards the Illinois shore.

These examinations show that melosira was present in all the samples; cyclotella was present in all but one, namely, in No. 2, that is it was missing from No. 2. Stephanodiscus was present in all the samples excepting No. 1. Protococcus was present in all samples except No. 1; synedra was present in samples Nos. 1, 2, 4, 7, 9, 10 and 11. Tabellaria was present in Nos. 1, 7, 8, 10 and 11. Dictyosphaerium was present in Nos. 8 to 11, and pediastrum in Nos. 7 to 11. Scenedesmus was present in No. 4 and in Nos. 7 to 11. Actinophrys was present in samples Nos. 8 to 11. The total numbers of organisms varied from 230 in sample No. 1 to 2628 in sample No. 10.

Q. Are those all the charts which you have, or tables?

A. Yes, sir.

MR. WOERNER: We now offer these tables or charts in evidence as complainant's exhibits, they being numbered from zero to 14, being 15 charts altogether.

THE COMMISSIONER: We will mark them complainant's Exhibits No. 46, with sub-numbers 1 to 15, inclusive.

Q. MR. WOERNER: Now, professor, what is a diatome and how does it differ from other microscopic organisms?

A. A diatome is a unicellular plant and perhaps its most important difference from other unicellular plants is the
3166 fact that its cell wall is so impregnated with silica that
it is practically an indestructible thing. That is, a diatome might be described as a little plant cell made of glass. The living matter lies within this silicious cell and after the death of the cell the walls of the cell remain just as they appear during life. In fact, they may be considered as fossil remains of a plant, and there are in existence today geological deposits which are composed almost entirely of diatomacious cells.

Q. Are they considered more hardy and more likely to survive the voyage from Lake Michigan down the various water courses, to the intake at St. Louis, than the other microscopic organisms or not?

A. Yes, sir; these cells being indestructible, or practically so, could be identified after a long passage through a river, and this cell wall being a strong protection to the cell offers more favorable resistance than many of the microscopic plants, such for example, as the blue-green algae or the green algae even.

Q. Where are these diatomes most likely to be found?

A. Diatomes are likely to be found in almost any kind of fresh water, but there are thousands of species of diatomes, and the particular diatomes with which we are concerned in those examinations, namely, asterionella, synedra, melosira, cyclotella, stephanodiscus and the others mentioned, are
3167 more commonly found in ponds and lakes and such bodies
of water, than they are elsewhere.

Q. Then you think they would not be found to any extent in the waters of running streams unless they came from elsewhere?

MR. TODD: I object to the question as being leading.

A. These organisms just enumerated, or these diatomes just enumerated are not as likely to be found in the waters of running streams, unless these streams are fed from lakes or ponds, or similar bodies of water.

Q. MR. WOERNER: Would they or would they not be found in running streams such as we find between Lake Michigan and the City of St. Louis, unless they came from other sources?

MR. TODD: I object to the question on the ground that it is leading.

A. Experience has shown that these organisms would not be likely to be found in the streams tributary to the Illinois River, except in so far as these streams are fed by lakes or ponds.

MR. TODD: I move to strike out the answer for the reason that what experience shows is not competent and that the answer is not responsive to the question.

MR. WOERNER: Professor, from your examination of these waters and the diatomes found in them by yourself, to what do you attribute their presence in the Illinois and the Mississippi rivers and the drainage canal?

3168 MR. TODD: What waters do you have reference to, Mr. Woerner?

MR. WOERNER: The waters I have reference to are the waters of the drainage canal, the Desplaines river, the Illinois river and the Mississippi river and also of Lake Michigan.

JUDGE SPRINGER: Mississippi river, at what point? There are four or five points that you have for the Mississippi above Grafton and at Chain of Rocks?

MR. JEFFRIES: At all points.

JUDGE SPRINGER: At all points.

MR. WOERNER: Well, I have asked him the question. Let him answer.

A. It is my opinion that the diatomes in the Illinois river above the point where it enters the Mississippi river at Grafton, came partly from Lake Michigan and partly from the tributaries of the Illinois river; that the waters of the Mississippi river from the various points below Grafton came partly from the upper Mississippi, from Lake Michigan and from the tributaries of the Illinois river. My answer being understood as to refer to the diatomes as a class, and without reference to particular genera or species.

Q. Are you able or not to say from your examinations and your knowledge upon this subject, whether any particular species of these diatomes or micro-organisms came from Lake Michigan, or not?

3169 A. There were certain diatomes found during my examinations which appeared to be characteristic of Lake Michigan and Lake Michigan alone. I would like to change that. Lake Michigan and nowhere else, excepting the streams below, to which the water from Lake Michigan had access.

Q. Can you say whether or not any of these micro-organisms which were peculiar to Lake Michigan, were found in the Mississippi river at the Intake and if so, state which ones they were and how they got there?

A. There was an organism which I will describe as synedra pulchella variety sub prolongata, which was found at the Intake of the waterworks at the Chain of Rocks, and which was found also in the water of Lake Michigan, but was not found in the water of the Missouri river, or the water of the upper Mississippi river, or in any of the tributaries of the Illinois river unless we consider the Chicago Drainage Canal as being a tributary.

Q. What do you mean by upper Mississippi river—beginning at what point?

A. When I use the term "upper Mississippi" in that last sentence I refer to that portion of the Mississippi river above the point where the Illinois river enters it at Grafton.

Q. Now, professor, have you tabulated the results of your examinations to show the average numbers of diatomes at the various places where you collected the samples? 3170

A. Yes, but I have not two copies of that. I have simply the copy which represents the results of my original figures which I can read.

Q. Yes, just read them.

A. (Witness refers to table.)

Q. Now, state what this table is and read it so that it will get into the record.

A. This table represents the averages of all the examinations made at each point to be enumerated, and for the entire period covered by the observations. The figures given being averages across the sheets horizontally—of the plates—of the sheets already presented in evidence in so far as they relate to the diatomes, or to the most important diatomes.

Q. Well, read that so it will get into the record as testimony.

A. I will read first this column of the list of samples and then read them out serially—the numbers of the samples—

Q. Whichever way you think is the most lucid.

A. Well, I will read the first column, which gives the location of the samples, and which corresponds to the titles of the sheets already presented. This is Lake Michigan, the first line; the second line is drainage canal at Lockport, and the third is the Desplaines river at Lockport; the next is all the
3171 tributaries of the Illinois River averaged together, the
Illinois river above Peoria; Illinois river at Beardstown, Illinois River at Grafton; Mississippi river above Grafton; Mississippi river at Alton; Missouri river at Bellefontaine, the Mississippi river near the Illinois shore opposite the Chain of Rocks, the Intake of the St. Louis Waterworks, and the settling basin of the St. Louis Waterworks. The table is as follows:

	Synedra........	Tabellaria........	Melosira........	Cyclotella........	Asterionella....	Stephanodiscus.
0. Lake Michigan...........	577	236	13	38	25	8
1. Dr. Canal—Lockport	270	236	13	30	22	2
2. Desplaines—Lockport ...	2	2	1	264	113	9
3. All tributaries Ill. R.....	17	3	2	709	13	1
4. Ill. R. above Peoria......	126	62	8	48	10	3
5. Ill. R. at Beardstown....	95	19	0	784	31	0
6. Ill. R. at Grafton........	90	46	8	4468	41	3
7. Miss. R. Grafton........	1	0-	2400-	1372	569	307
8. Miss. R. at Alton........	19	16	1741	2534	124	174
9. Mo. River	5	0	22	16	0	6
10. Miss., Ill. shore	51	21	1380	1957	396	192
11. Intake	16	0	403	443	40	93
12. Settling Basin	0	12	0	256	68	10

3172 MR. JEFFRIES: Now I wish you would state in general terms, professor, what that table shows?

A. It contains the average results of the number of most important diatomes present at the various places between Lake Michigan and the settling basin of the St. Louis waterworks where samples were collected.

Q. It gives the location of the samples?

A. It gives the location of the samples and the average numbers of the most important diatomes for each of these locations throughout the entire period covered by this investigation.

Q. Does it give the names of the diatomes?

A. It gives the names of the diatomes and the average number of each for each place.

Q. What significant features do you notice in connection with this table and the respective diatomes, if any?

A. I notice that certain diatomes are especially characteristic of certain waters. In all cases these are not necessarily found only in these waters, but that they are in point of numbers—

Q. Now state what they are and why you think it is significant?

A. Well, take first the synedra. The average number of synedra found in Lake Michigan, was 577 standard units 3173 per cubic centimeter. The average number of synedra found in the Illinois River at Grafton was 90. When I say 90 I mean in every case standard units per cubic centimeter. The average number found in the Mississippi River above Grafton was 1; the average number found in the Missouri River at Bellefontaine was 5; the average number found in the intake of the St. Louis waterworks was 16; the average number found in the Mississippi River at the Illinois shore opposite the chain of rocks, was 51; while there were none found in the settling basin of the waterworks.

Q. Now what conclusion do you draw from that?

A. I should draw this conclusion, that the 16 synedra which were found in the intake of the St. Louis waterworks, came not from the Missouri River, nor from the Mississippi River at a point above Grafton, but rather from the Illinois River at Grafton, and if we consider that there were 577 synedra in Lake Michigan, with only an average of 17 per cubic centimeter in all the tributaries of the Illinois River, I should conclude that the chances were that the 16 organisms found at the intake of the St. Louis waterworks, or most of them, came from Lake Michigan.

Q. Now with respect to some of these other diatomes, did you notice anything of consequence with reference to them?

A. That is considered tabellaria; there were 236 tabellaria per cubic centimeter on an average, in the water of Lake Michigan.

3174 Well now, the average in the tributaries of the Illinois was about 3.

The average in the Illinois River at Grafton was 46. There were none found in the Mississippi River just above Grafton.

There were none found in the Missouri River.

There were 21 found in the Mississippi River near the Illinois shore opposite the chain of rocks.

There were none found in the intake of the waterworks but there were 12 found in the settling basin of the St. Louis waterworks.

Q. Now what conclusion would you draw from that?

A. This conclusion, that in all probability the tabellaria found in the settling basin of the St. Louis waterworks, and at a point in the Mississippi River near the Illinois shore, came not from the Missouri River or from the Mississippi River at a point above Grafton, but from Lake Michigan by means of the Illinois River and not from any of the tributaries of the Illinois.

Q. Did you make any other comparative tables from the samples of those different classes of diatomes?

A. I have more on the same table that I haven't explained.

Q. Go ahead.

A. Let us consider the melosira, which is an organism.

3175 The average number of melosira was 13 at Lake Michigan, 2 in the tributaries of the Illinois River, 8 in the Illinois River at Grafton, 24 in the Mississippi River above Grafton; 22 in the Missouri River at Bellefontaine; 1380 in the Mississippi River near the Illinois shore at chain of rocks, and 403 in the intake of the St. Louis waterworks at the chain of rocks.

Q. Any others?

A. Shall I go on as I did in the other organisms?

Q. Yes, go through all of those.

A. The conclusion from these figures being that for the most part the melosira found at the intake of the St. Louis waterworks and at the Mississippi River near the Illinois shore were derived not from the Illinois River or from Lake Michigan or from any of the tributaries of the Illinois, but rather from the Mississippi River above Grafton.

Q. Go right down the line with all those long names?

A. Now consider the cyclotella; there were 38 in Lake Michigan. 700 on an average in the tributaries of the Illinois River, 4468 in the Illinois River at Grafton.

1372 in the Mississippi River above Grafton,

16 in the Missouri River at Bellefontaine,

1957 near the Illinois shore opposite chain of rocks,

443 at the Intake of the waterworks of St. Louis at the chain of rocks.

3176 The conclusion being that these cyclotella found at the intake of the St. Louis Waterworks at the chain of rocks, came for the most part, not from the Missouri River, but from the Mississippi River and the Illinois River, and only to a slight extent from Lake Michigan. The cyclotella found in the Illinois River at Grafton being derived not from Lake Michigan, but from one or more of the tributaries.

Q. Do you mean the cyclotella?

A. Yes, of the Illinois River. Now consider the asterionella. There were 25 in Lake Michigan,

There were 13 on an average in the tributaries of the Illinois River.

There were 41 on an average in the Illinois River at Grafton.

There were 569 in the Mississippi River above Grafton;

There were none in the Missouri River;

There were 396 in the Illinois shore, opposite the chain of rocks.

There were 40 at the intake of the St. Louis waterworks at the chain of rocks.

The conclusion being that for the most part the asterionella found at the intake of the St. Louis waterworks and at the Missouri shore or at the Illinois shore opposite the chain of rocks were derived not at all from the Missouri River, but chiefly from the Mississippi River above Grafton, but in
3177 part from the Illinois River and its tributaries and Lake Michigan.

Now the stephanodiscus. It was found to the extent of 8 per cubic centimeter in Lake Michigan and the average of 1 in the tributaries of the Illinois River;

3 in the Illinois River at Grafton,

307 in the Mississippi River above Grafton.

6 in the Missouri River at Bellefontaine,

192 in the Mississippi River at the Illinois shore opposite the chain of rocks,

93 in the intake of the St. Louis waterworks.

From which I conclude that of the stephanodiscus—of that the majority of the stephanodiscus found at the intake of the St. Louis waterworks, and at the Illinois shore opposite the chain of rocks, were derived not so much from the Missouri River or the Illinois River, as from the Mississippi River above Grafton.

Q. Now professor, do the synedra found in the tributaries of the Illinois differ from those found in Lake Michigan? If so, how do they differ?

A. The synedra found in Lake Michigan belong to the species pulchella and variety sub prolongata, while the synedra found in the tributaries of the Illinois River were either the synedra lonslotta, or the synedra pulchella variety curta.

3178 Q. Are they easily distinguishable?

A. The synedra pulchella are very easily distinguishable from the snyedra lonslotta, because of the different shape, while the synedra pulchella, variety sub prolongata differ from the synedra pulchella variety curta in their size; the subprolongata being in round numbers, twice as large as the variety curta. All three of these forms of synedra are very easily distinguishable under the powers of the microscope used in the examination.

Q. Would this enable you to distinguish which came from Lake Michigan and which came from other sources when they were taken from the waters at the Intake?

A. Yes sir.

Q. And you did so?

A. Yes sir.

Q. Now those that were taken from the intake, did you find the species that you say was found in Lake Michigan only; I mean that originates in Lake Michigan only?

A. I found both. I found the synedra pulchella variety sub prolongata at the intake of the St. Louis waterworks; I think on November 12th if I recollect the date correctly.

Q. To what did you attribute their origin, that is, where they originally came from?

A. So far as all of my examinations show, I should say that they came from Lake Michigan.

3179 Q. Did you make a chart of the comparative number of these different diatomes in various sections?

A. I made charts of those which were most prominent; I did not of all.

Q. Have you those charts with you?

A. Yes sir.

Q. You made those charts from your own examinations, did you?

A. Yes sir.

Q. Now these charts depict graphically the results of your investigations, do they?

A. Yes sir.

Q. I wish you would explain the various charts beginning nearest to Lake Michigan, or in Lake Michigan as the case may be; explain what the charts are and what they indicate and what your numbers say and what you mean to illustrate by them?

A. I present first this diagram No. 1, which gives the results of the determinations of synedra pulchella, per cubic centimeter, at the various places between Lake Michigan and the intake of the St. Louis waterworks at the chain of rocks.

The upper section of the chart shows the number of synedra pulchella at different days in Lake Michigan, The second section of the chart shows the number at the Chicago Drainage Canal at Lockport.

The next section shows the number in the Illinois River above Peoria.

3180 The next section shows the number in the Illinois River at Beardstown.

The next section shows the number in the Illinois River at Grafton.

The next section shows the number in the Mississippi River at Alton.

The next section shows the number in the Mississippi River opposite the chain of rocks,

While the last one shows the number in the Mississippi River at the intake of the St. Louis waterworks.

It would be noticed that I did not include in this diagram the numbers in the Mississippi River above Grafton, or the numbers in the Missouri River at Bellefontaine, for the reason that in the first case the numbers do not exceed 8 per cubic centimeter, or in the second case 10 per cubic centimeter, numbers which would be so low that it would be scarcely seen upon the scale used.

This diagram shows in a general way the decrease of the synedra pulchella between Lake Michigan and the Intake of the waterworks at St. Louis, at chain of rocks.

Q. That is chart No. 1?

A. Yes sir, that is chart No. 1.

Q. What does the next chart or diagram show?

A. The next diagram is known as diagram No. 2, and is
3181 drawn by the same plan as the preceding, and shows the numbers of tabellaria fanistrata at the points enumerated on the different sections.

The first section or upper section shows the number in Lake Michigan.

The second section shows the number in the Chicago Drainage Canal at Lockport,

The next section in the Illinois River above Peoria,

The next section in the Illinois River at Beardstown, and the next section in the Illinois River at Grafton, the next section in the Illinois River at Alton, the next section in the Mississippi River, Illinois shore, at chain of rocks,

and the next section at the intake of the St. Louis waterworks where there was none,

and the next in the settling basin at the chain of Rocks.

During this *period there is noted at the top* of this diagram—I state that during this period no tabellaria fanistrata was found in the Mississippi River above Grafton, or in the Missouri River at Bellefontaine.

This diagram shows in a general way the decrease in the number of tabellaria fanistrata between Lake Mich-
3182 igan and the settling basin at the chain of rocks.

Q. What is that line drawn down the center of the chart?

A. That serves to separate the month of October from the month of November. The vertical line drawn down the center of the diagram serves to separate the observations made during the month of October, from those made during the month of November. The observations which were made by me beginning on October 15th and continuing from that through November.

The next diagram, being diagram No. 3, shows the number of standard units of microscopic organisms actually discharged with the pollution by the various towns between Lake Michigan and noted at the bottom of the diagram, and states that the organisms included in the above are:

Cladothrix,
Beggiatoa,
Anthrophysa,
Bussasia,
Ciliata,
Euglena,
Monas,
Trachelomonas,
Vorticella,
Trachelocerea,
Paramacium,
Pleuromona,

3183 These are arranged to show the numbers of the organisms mentioned in the preceding list that I had covered by examinations. The observations during October being to the left of the central line and those for November being to the right.

The upper section shows the number found in Lake Michigan; the next section those found in the Chicago drainage canal at Lockport;

The next section shows those found in the Illinois river above Peoria.

The next section shows those found in the Illinois River at Beardstown.

The next section shows those found in the Illinois River at Grafton.

The next section shows those found in the Mississippi River just above Grafton.

The next section shows those found in the Mississippi River at Alton.

The next section shows those found in the Missouri River at Bellefontaine.

The next section shows those found in the Mississippi River at the Illinois shore opposite the chain of rocks,

the next section those in the intake of the St. Louis waterworks.

This diagram shows that the organisms were very few
3184 in Lake Michigan, and that they were quite numerous in
the Chicago drainage Canal and the Illinois River and that they were entirely absent from the Mississippi River above Grafton, and from the Missouri River at Bellefontaine, and that they were found in the Illinois River or rather in the Mississippi River at the Illinois shore opposite the chain of rocks and at the intake of the St. Louis waterworks.

The next diagram shows the number of melosira granulata at various points in the Mississippi River.

The upper section showing the number in the Mississippi River above Grafton;

The next section showing the number in the Mississippi River at Alton,

The next section showing the number in the Mississippi River, Illinois shore, opposite chain of rocks, and the next section showing the number in the intake of the St. Louis waterworks at the chain of rocks.

And the note at the bottom states that during this period the number of melosira granulata in the Illinois River at Grafton did not exceed 24 per cubic centimeter, standard units, and in the Missouri River at Bellefontaine, they did not exceed 60 per cubic centimeter, the quantity being so low they would scarcely appear on this sheet.

3185 The results indicate that during the period covered by the investigation there was a gradual decrease in the number in the Mississippi river at Grafton, and that this decrease was also noted at Alton in the Mississippi River and at the Illinois shore opposite the chain of rocks, and also at the intake of the waterworks at the chain of rocks.

The next number is diagram No. 5 and shows the number of cyclotella operculata at various points in the Mississippi River and at the Illinois River at Grafton.

The upper section shows the number in the Mississippi River above Grafton;

The next section in the Illinois River at Grafton;

The next section in the Mississippi River at Alton;

The next section in the Mississippi River, Illinois shore, opposite chain of rocks;

And the last section in the Mississippi River at the intake of the St. Louis waterworks,

And the note states that during this period the cyclotella operculata did not exceed 60 per cubic centimeter in the Missouri River at Bellefontaine, but the results indicate that during the latter part of November there was an enormous increase in the cyclotella operculata in the Illinois River at Grafton, the numbers being so great it could not be shown upon the scale of this diagram; and that this increase was also
3186 noted at Alton, at the Illinois shore, chain of rocks, and at the intake of the St. Louis waterworks.

The next diagram, No. 6 shows the results of the examinations made of samples collected at twelve points in the cross-section across the Mississippi River above Alton.

It shows the results of the microscopic organisms and it also shows the results of certain turbidity and color observations which I have not yet put in the testimony.

The upper line shows the turbidity of the water at the different stations expressed in terms of the silica standard.

MR. TODD: I suggest in order that these charts may be more intelligible, that there has been no evidence introduced as the Professor says, in regard to some of them.

MR. WOERNER: I will ask him about that as soon as he gets through.

THE WITNESS: (Answer continued) The second section shows the color of the water at the different stations expressed in terms of the platinum cobalt standard.

The next section shows the number of microscopic organisms characteristic of the Mississippi River, indicated by lines of different character, the full line referring to the total organisms; the melosira being expressed by the dash line, the cyclotella by the dotted line, and the stephanodiscus by
3187 the dot-dash line.

The last section on the sheet shows the microscopic organisms characteristic of Lake Michigan. The synedra expressed by the full line and the tabellaria expressed by the dash-line.

The results show that the turbidity was fairly constant across the stream, but that it was lower on the eastern shore than on the western.

Q. What is the number of that chart?

A. No. 6.

JUDGE SPRINGER: Lower on the Illinois shore?

A. Yes. These diagrams being based just as the tables were, with the numbers of the Missouri shore on the left of the diagram, and the numbers of the Illinois shore on the right of the diagram.

3188 Q. Explain what turbidity means?

A. The turbidity of the water means its opacity to light, or its opacity or opposition to the passage of the rays of light and is a measure of the suspended matter present. Observations of turbidity are frequently made instead of determinations of suspended matter because of the much greater convenience of the method.

The diagram shows that there was in general a gradual decrease of color from the Missouri shore towards the Illinois shore, and that the color was particularly low near the Illinois shore. The diagram also shows that the melosira, which as has previously been offered in testimony, were especially characteristic of the waters of the Mississippi River above Grafton,—decrease generally from the Missouri shore towards the Illinois shore, while the cyclotella, which were found in both the Illinois River and the Mississippi River, but were more abundant in the Mississippi River at the time when the cross section was made, were fairly constant across the river excepting near the Illinois shore, while the stephanodiscus were nearly uniform across the stream, but showed a slight tendency to decrease towards the Illinois shore.

The synedra, which were charactertistic of Lake Michigan, were not present in samples 1 to 5, and were most abundant in sample 7; while tabellaria, which also was especially characteristic of Lake Michigan, were not found in 3189 samples 1 to 4, or in samples 7 and 8, but were found in the other samples.

This last diagram is No. 7 and it shows the results of the observations of the samples taken in the cross section of the Mississippi River about one mile above the chain of rocks and it shows the turbidity of the water at each station; the color at each station and there is a line showing the comparative abundance of melosira, cyclotella and stephanodiscus organisms which at that time were especially characteristic of the Mississippi River above Grafton, and a line showing the synedra and tabellaria organisms which at that time were especially characteristic of Lake Michigan. These samples were collected on November 10th, 1901. These are the turbidity observations shown on this diagram and indicate a progressive decrease from the Missouri shore towards the Illinois shore, while the color progressively increases from the Missouri shore towards the Illinois shore. The lines at the bottom of the diagram show the progressive increase in the melosira, cyclotella and stephanodiscus, speaking in a general way, from the Missouri shore towards the Illinois shore, while the same is practically true of the synedra, an organism especially characteristic of Lake Michigan. The tabellaria, which was characteristic of Lake Michigan, was not found west of station 7. It will be noticed however, that

all of these organisms which were characteristic of Mis-
3190 sissippi river water, were found at station 1, and that the synedra, which was characteristic of the water of Lake Michigan, was also found at stations 1, 2, 3 and 4.

MR. WOERNER: We offer the diagrams in evidence as exhibits to the testimony of Professor Whipple, as Complainant's Exhibit No. 47—sub-numbers 1 to 7 inclusive. So marked by the Commissioner.

MR. WOERNER: Professor, in regard to the tests of color, you made them yourself?

A. I made those tests personally.

Q. And the result was as you have stated, and as indicated on the diagram from which you have given this testimony?

A. Yes sir.

Q. I will ask you, professor, whether you are able to form an opinion from your examinations and the results thereof, as depicted on these diagrams, as to the relative amount of water that enters the intake—as to the relative amount of water coming from the Illinois and the Missouri Rivers—I will ask you first whether the relative amounts of waters from these streams are capable of being determined from these data?

A. Yes sir, I think that they are.

Q. Did you make any calculations in that respect?

A. Yes sir, I made calculations from the table of averages which has been submitted, and I made those determinations from this table of averages.

3191 MR. JEFFRIES: Averages of what?

A. Averages of the relative numbers of melosira, cyclotella, asterionella and stephanodiscus present in the intake of the St. Louis waterworks, in the Missouri River at Bellefontaine, and in the Mississippi River at Alton.

Q. And the Illinois River at any point?

A. As I understood his question it referred to the proportion of Mississippi River water and Missouri River water.

MR. WOERNER: By the Mississippi, you mean the waters of the Mississippi and also those that enter from the Illinois?

A. Yes sir.

Q. You include that in the Mississippi, do you?

A. Yes sir.

Q. State in a general way what you did, and what the results of your calculations were?

A. I assume for the purpose of this calculation, that the samples which were collected at the Missouri River at Bellefontaine, represented the character of the water in the Missouri River, and that the samples which were collected in the Mississippi River at Alton represented the character of the Mississippi River just above the point, or above the point where the Missouri River enters the Mississippi, and I compared the average results of these various organisms enumerated, with the average results of similar organisms found in the water at the intake of St. Louis waterworks.

3192 Q. Now, one moment; are you for the present leaving out of consideration the turbidity of the water, or is that entering into your calculations

A. In this calculation I am considering only the average results of the melosira, the cyclotella and the asterionella, and the stephanodiscus, which were found in the places mentioned.

Q. Now what were your conclusions?

A. I concluded that on an average 32 per cent of the water which entered the Intake of the St. Louis waterworks was considered as Mississippi River water, and that 68 per cent of the water was Missouri River water.

Q. Is that result arrived at by calculation or by guess work?

A. By mathematical calculation.

JUDGE SPRINGER: As to what?

A. By mathematical calculation based on the relative abundance of the four organisms enumerated in the Missouri River, in the Mississippi River at Alton, and at the intake of the St. Louis waterworks.

MR. WOERNER: Did you make any calculations of the relative percentages of the waters of these two streams based on the turbidity and color of the water?

A. I did, but I have not my figures at hand at this mom-ment. I can put that in.

3193 Q. Now, Professor, what tests did you make with respect to the turbidity and color of the water in the respective streams?

A. I made turbidity observations and observations of color in the samples taken from the two cross sections, one at Alton just above Alton, and the other one mile above the chain of rocks.

Q. What was your purpose in doing that?

A. *To find the relative turbidity of the water across the* stream at the different points, and the relative color across the stream at the different points.

JUDGE SPRINGER: When was this, November, 1901?

A. Yes, the first section was taken on November 10th, and the second November 12.

MR. WOERNER: Well, what results did you obtain?

A. I can read these results from the original records which I have here and with your permission I will read them as to columns. If we consider first the section across the Mississippi river above Alton taken on November 12, we have the following list of turbidity expressed in terms of silica standard:

No. of Sample.	Turbidity.	Color.
1.	18	34
2.	14	32
3.	14	33
4.	12	33
5.	13	29
6.	15	25
7.	15	25
8.	14	26
9.	16	24
10.	11	23
11.	12	23
12.	12	21

3194

That is all of that section.

Q. At what point is that?

A. At a point one mile above Alton.

JUDGE SPRINGER: What is your explanation of these figures as to turbidity and color?

A. When I say that the turbidity of a sample is 18, it means that that sample is just as turbid as it would be if it contained 18 parts per million of what we call the silica standard, or 18 parts per million of finely divided silica, which is prepared according to a definite formula.

Q. Passing from technicalities, what is the common explanation of this turbidity?

A. The turbidity?

Q. Yes, passing from your technical terms, what do you say it is?

A. I have already stated in the record that the turbidity is the opaqueness of the water, as you hold it to the light.

3195 Q. The relative opaqueness then would be arrived at by what?

A. The relative opaqueness would be arrived at by the turbidity, and the higher the number the greater the turbidity, or the greater the opaqueness.

Q. What are the limits of your numbers?

MR. WOERNER: What the judge means is what do you take as a standard?

A. The unit of turbidity, or water which contains one part in a million of this silica standard.

MR. WOERNER: So you mean parts per million?

A. When I say it is 18 it is equivalent in turbidity to a solution prepared by adding 18 parts of turbidity.

JUDGE SPRINGER: Per million?

A. Per million, by weight.

JUDGE SPRINGER: How about color; how do you explain that?

A. The color is measured by comparing the sample of water after removing the suspended matter, with arbitrary standards, which are varied in color by the addition of different amounts of platinic chloride, and when I say that the color of the water is 34, it means that the color is as dark as an artificial solution which contains 34 parts per million of this platinum salt.

Judge SPRINGER: The lower the numbers the brighter they become?

3196 A. The higher the number the more colored the water is.

Q. What is your unit?

A. The unit being one part in a million of this platinum salt.

MR. WOERNER: Now this sample was taken at what point?

A. I have given you one cross section; I have not given you the second.

Q. Where is this cross-section?

A. The one that I have read is one mile above Alton. The second cross section was taken one mile above the chain of rocks and consisted of eleven samples numbered from 1 to 11, from the Misouri shore to the Illinois shore, and I will read the turbidity and color just as before:

No. of sample	Turbidity.	Color.
1.	2200	18
2.	1700	19
3.	1560	18
4.	1140	22
5.	800	24
6.	430	26
7.	190	29
8.	140	34
9.	110	37
10.	35	43
11.	18	48

3197 MR. WOERNER: Now Professor, I want to ask you when these samples were taken and from whom you received these?

A. The samples of this cross-section just mentiond were collected on November 10th.

Q. What year?

A. Of 1901, by Dr. Ravold's brother, Edward, I think his name is. I have it marked "Ed."

G. C. WHIPPLE.

ADJOURNED until Tuesday, May 12th, 1903, at 10:00 A. M. Southern Hotel, St. Louis.

Southern Hotel, St. Louis, Missouri.

3198 10:00 A. M., Tuesday, May 12, 1903.

Continuation pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

GEORGE CHANDLER WHIPPLE,

Resumed the stand for futher

DIRECT-EXAMINATION,

By Mr. Jeffries.

Q. Mr. Whipple, state whether you received some samples of water from Professor Van Ornum during the month of March, 1903?

A. Not during the month of March.

Q. Month of April?

A. But during the month of April I did.

Q. Now state where you receiver those samples and how you received them?

A. They were received at my laboratory in Brooklyn, some on April 14th, and some on April 16th.

Q. Do you know how many samples you received?

A. I received sixty-eight.

Q. Who did you receive them from?

A. From Professor Van Ornum.

3199 Q. Do you know what they were?

A. They were marked in the following method, or a method which Professor Van Ornum has already mentioned in his testimony. Shall I give the method again?

Q. Yes, give the method again.

A. I received eight samples with tags upon which there was a capital "M." This capital M was followed by a serial number from 1 to 8, and this number was followed in each case by the small letter "b." I also received—

Q. Now what did they represent?

A. I received a letter from Professor Van Ornum in which he stated that the capital letter M referred to a cross-section about one-quarter of a mile above the mouth of the Missouri River, across the Mississippi River, and that the serial numbers from 1 to 8 represented stations in that cross section, beginning with the Missouri shore and running across to the Illinois shore, and stating further that the samples were spaced 200 feet apart, and also that the letter "b" meant that the sample was collected at a depth of 10 feet below the surface. Upon each tag there were also figures indicating the temperature of the water in degrees Fahrenheit.

Q. Now did you receive any other samples?

A. On the same date I received other samples marked with a capital letter I, and with serial numbers running from 1 to 12. These serial numbers being followed by small letters,
3200 either a, b or c, and the tag also included the temperature of the water. In three instances, namely, the samples marked with the serial numbers, 10, 11 and 12, bottles were received which bore the small letters b and c, and in Professor Van Orum's letter he stated that at that station the water was not over ten feet deep and consequently the b sample also represented the bottom as nearly as possible.

JUDGE JOHNS: You didn't give us the number, Professor, of I.

A. The number of the samples?

Q. Yes?

A. I thought I did,—from 1 to 12.

Q. No, but the number of bottles?

A. Thirty-three.

Q. Marked "I"?

A. 33 bottles marked "I."

Q. MR. JEFFRIES: Now that was a cross section of what?

A. According to the letter which I received from Professor Van Ornum, the capital letter "I" referred to a cross section of the Mississippi River above the intake of the water works at the chain of rocks. The serial numbers from 1 to 12 represented the stations across the river from the Missouri shore towards the Illinois shore,—the samples of the stations being 400 feet apart.

The small letter "a" meant that the sample was taken
3201 at the surface or near the surface.

The small letter "b" indicated that the sample was collected at a depth of 10 feet, and the small letter "c" that the sample was collected at or near the bottom of the stream.

Q. Now is that all the samples you received?

A. That was all that I received on April 14th.

Q. Now when did you receive the next?

A. On April 16th, I received three samples which were marked with the capital letter B and which had serial numbers from 1 to 3. In each case the serial number was followed by the small letter "b" and in each case was recorded the temperature of the water.

The letter which I received from Professor Van Ornum stated that series B, or that the samples marked with a capital letter B represented a cross section of the Missouri River just above its mouth. Serial number 1 being near the south shore; number 2 being in mid-stream and number 3 being near the north shore.

I also received 24 samples which were marked with a capital letter C, and which were followed by numerals from 1 to 8, or serial numbers from 1 to 8, and which had after the serial numbers, small letters, either, a, b or c. The tags also bore the temperature of the water.

Q. Now what did the a, b and c represent?

A. The small letter "a," according to Professor Van Ornum's letter, represented a sample of water at or just below the surface of the stream. Small "b" represented the water at a depth of ten feet; small "c" represented the water at the bottom, but at stations 1, 2, 3, 4, 5 and 7, the small letter "c" was folowed by the figures 30 feet, and according to Professor Van Ornum's letter these "c" samples which were followed by the figures 30 feet, were taken not at the bottom, but at a depth of 30 feet and I understand that the reason for this was that the cord attached to the sampling apparatus did not permit of his collecting samples at a depth greater than 30 feet. 3202

I understand from his letter that the samples which were marked with a capital C were collected across the Mississippi River below the point where the Missouri River enters it, and that the serial numbers run from 1 near the Missouri shore, to 8 near the Illinois shore, and that the stations were 200 feet apart. In his letter he further stated that sample No. 1 was taken at a distance of about 800 feet from the Missouri shore.

Q. Now that cross section was taken where?

A. Across the Mississippi River below the point where the Missouri River enters.

Q. Now you made an examination of those samples, did you?

A. I examined all of these samples for turbidity.

Q. What was the character of bottle that they came in, and state whether or not the water was properly bottled to 3203 make an examination for turbidity?

A. The samples were received in glass bottles, which held approximately one quart, and the bottles had cork stoppers. The bottles were nearly full in every case, and there was sufficient water in each to make the determination for turbidity.

Q. Now you made that determination?

A. Yes sir.

Q. Have you the results of the determination?

A. Yes sir.

Q. Will you give them?

A. I can call them off, I think easier.

Q. Now in calling them off, state the particular cross section to which the explanation applies?

A. The first list will give the results in cross section M which was in the Mississippi River just above the mouth of the Missouri River, the exact location having been testified to by Professor Van Ornum. Sample marked M 1 b, the M being a capital letter, the "b" being a small letter, had a turbidity of 127.

Q. Now in ascertaining the turbidity of those samples, you used the same unit or standard of measure as testified to yesterday with reference to obtaining the turbidity of the water?

A. Yes sir.

3204 MR. WOERNER: When you say one hundred and twenty-seven do you mean one hundred and twenty-seven or one and twenty-seven hundredths?

A. One hundred and twenty-seven.

JUDGE SPRINGER: Parts per million?

A. And when I say 127 I mean that the water was as turbid as it would be if it contained 127 parts per million by weight of the specially prepared silica used in measuring turbidity according to this method.

MR. JEFFRIES: And that silica is what?

A. The silica is prepared from diatomacious earth and is carefully washed and ground before used for preparing the standards.

Q. Now then, go ahead and give your results?

A. To repeat: Sample M 1 b had a turbidity of 127—

Q. Now then, what end of the cross section was that on or which side of the river?

A. On the Missouri side.

Sample M 2 b, turbidity 152,
Sample M 3 b, turbidity 147,
Sample M 4 b, turbidity 135,
Sample M 5 b, turbidity 175,
Sample M 6 b, turbidity 100,
3205 Sample M 7 b, turbidity 100,
Sample M 8 b, turbidity 80.

Q. Now those samples, according to that explanation were taken at ten feet beneath the surface of the water?

A. Yes sir. Will you have the next one?

Q. Yes?

A. The next series were section B, which was taken across the Missouri River, the serial numbers running from the south shore to the north shore:

Sample B 1 b, had a turbidity of 1400,
Sample B 2 b, had a turbidity of 1540,
Sample B 3 b, had a turbidity of 1540.

That is all in that section.

JUDGE SPRINGER: Where is that section?

A. That is across the Missouri River just above its mouth.

The next section is series C, which represents a cross section of the Mississippi River below the point where the Missouri River enters.

Sample C 1 a had a turbidity of 1680,
Sample C 1 b had a turbidity of 1480,
Sample C 1 c 30 feet, had a turbidity of 1500.
Sample C 2 a had a turbidity of 1280,
Sample C 2 b had a turbidity of 1520,
Sample C 2 c 30 feet had a turbidity of 1420,
3206 Sample C 3 a had a turbidity of 800,

Sample C 3 b had a turbidity of 700,
Sample C 3 c 30 feet had a turbidity of 760,
Sample C 4 a had a turbidity of 690,
Sample C 4 b had a turbidity of 720,
Sample C 4 c, 30 feet had a turbidity of 740,
Sample C 5 a had a turbidity of 720,
Sample C 5 b had a turbidity of 730,
Sample C 5 c, 30 feet, had a turbidity of 780,
Sample C 6 a had a turbidity of 420,
Sample C 6 b had a turbidity of 550,
Sample C 6 c had a turbidity of 560,
Sample C 7 a had a turbidity of 315,
Sample C 7 b had a turbidity of 270,
Sample C 7 c, 30 feet, had a turbidity of 290,
Sample C 8 a had a turbidity of 245,
Sample C 8 b had a turbidity of 240,
Sample C 8 c had a turbidity of 240,

That is all of that series.

The next series is series I, which represents a cross section of the Mississippi River above the intake of the St. Louis waterworks.

Sample I 1 a had a turbidity of 1500,
Sample I 1 b had a turbidity of 1200,
Sample I 1 c had a turbidity of 1120,
3207 Sample I 2 a had a turbidity of 1020,
Sample I 2 b had a turbidity of 1160,
Sample I 2 c had a turbidity of 1120,
Sample I 3 a had a turbidity of 750,
Sample I 3 b had a turbidity of 720,
Sample I 3 c had a turbidity of 880,
Sample I 4 a had a turbidity of 250,
Sample I 4 b had a turbidity of 160,
Sample I 4 c had a turbidity of 380,
Sample I 5 a had a turbidity of 158,
Sample I 5 b had a turbidity of 157,
Sample I 5 c had a turbidity of 142,
Sample I 6 a had a turbidity of 95,
Sample I 6 b had a turbidity of 110,

Sample I 6 c had a turbidity of 100,
Sample I 7 a had a turbidity of 95,
Sample I 7 b had a turbidity of 95,
Sample I 7 c had a turbidity of 100,
Sample I 8 a had a turbidity of 100,
Sample I 8 b had a turbidity of 100,
Sample I 8 c had a turbidity of 110,
Sample I 9 a had turbidity of 85,
Sample I 9 b had a turbidity of 100,
Sample I 9 c had a turbidity of 105,
3208 Sample I 10 a had a turbidity of 100,

Sample I 10 b-c—both letters being on the tag,—had a turbidity of 110.

Sample I 11 a had a turbidity of 100,
Sample I 11 b-c had a turbidity of 97,
Sample I 12 a had a turbidity of 95,
Sample I 12 b-c had a turbidity of 90.

That is all of that.

MR. JEFFRIES: From what shore of the Mississippi River do these cross sections commence, as far as the numbers are concerned?

A. The cross-sections in the Mississippi River begin nearest the Misouri shore and run across towards the Illinois shore.

Q. From 1?

A. From 1 serially up to the highest number.

Q. Can you examine some of the bottles contained in complainant's Exhibit 45, and state in detail the character of your observations with reference to the turbidity of this water?

A. Do you want me to exhibit each sample?

Q. I don't know as it is necessary to exhibit each sample, but enough of them to get in this record a practical demonstration of it.

A. (Witness exhibits 12 bottles of water from Complainant's Exhibit 45).

3209 Q. Now what have you before you, Professor?

A. I see twelve samples, marked with the capital letter I, all with the small letter "b" and with serial numbers running from 1 to 12, excepting that the last three samples have the b-c.

Q. Now they were taken from complainant's Exhibit 45 were they?

A. Yes sir.

Q. Now the letters, numbers and the figures represent respectively the location, depth and temperature of the water from which the samples were taken, do they not?

A. The capital letter represents the location of the section, the serial numbers the station in that section beginning with the Missouri shore and running towards the Illinois shore, and the small letter representing the depth—the letter "b" representing the depth of 10 feet and the other figures the temperature.

Q. Is the temperature regular or irregular on all of the samples, comparatively speaking?

A. It is comparatively regular between slight limits.

Q. Now then explain in detail from these bottles of water the manner of your observation, with the view to obtaining the turbidity of the water?

A. Do you mean you want to know how I obtained the turbidity?

Q. Yes?

3210 A. We have in the laboratory an instrument known as the turbidimeter,—it consists of a tube of glass which is placed inside of a metal tube, and both of which are placed over a standard candle. It is so arranged that one can look down vertically through the tube and see the candle, and in the operation of measuring the turbidity, the apparatus is carried into a dark room in order to prevent the influence of daylight. With the glass tube held over the candle, the sample, after thoroughly shaking, is poured into the glass tube until the flame of the candle ceases to be visible. The tube is graduated in figures which represent the turbidity according to the silica standard, and this graduation is made by first calibrating the tube, using the standard preparation of silica. When the calibration has been made the figures on the tube are permanent, and the work is done once for all. For instance, if we pour into the tube some of our silica standard which contains 100 parts per million of silica, we will find that the candle flame will disappear at a certain point. This point is marked on the tube as 100. If later on a sample of water is poured into the tube and the flame of the candle disappears at this mark, we say that this sample also has a turbidity of 100. That is the method used in making these observations.

Q. Now I notice in comparing sample 1 with serial number 12 a difference in the coloring of the contents of the bottles. Explain the difference in the turbidity of those waters, without reference to the percentage of turbidity or anything of that kind? 3211

A. When you say that you observe a difference in the coloring appearance I assume that you mean a difference in the color as viewed by the eye, but I would like to offer a word of explanation, that when we speak of the color of water technically we refer not to the suspended matter present, but rather to the stain which the water has, and which is due to substances in solution. Therefore, the apparent color as you use the term or as I understand that you use the term, refers to turbidity and not to the true color as I used the term yesterday in my testimony.

Q. What I wanted to know was for you to explain the comparative difference between the two samples from the standpoint of coloration as viewed by the naked eye, in the ordinary acceptation of the term,—color, without reference to the science of chemistry or any other scientific examination of water?

A. Sample No. 1 is very much more turbid than sample No. 12.

GENERAL HAMLIN: As I understand your question, Mr. Jeffries, you want to know what causes that?

MR. JEFFRIES: Well, I am going to get to that.

Q. Now then, what causes this obvious difference between the coloring of the two waters, as viewed by the naked eye, speaking from the standpoint of a layman? 3212

A. Well, the presence of matter in suspension.

Q. Now does the coloring of which we now speak have anything to do with the color and odor of water from a sanitary scientific standpoint?

A. The turbidities in all of these samples are so great that the true color, using the term in its technical sense, could not be observed. There is no necessary relation between the turbidity of these samples and any odor which you might have of sanitary significanse.

Q. Now while we have these samples before us, I will ask you to explain so as to get it into the record, and state whether or not this degree of turbidity commencing on the Missouri shore, decreases continuously as you approach the Illinois shore, as viewed by the naked eye—from an occular observation?

A. Comparing these samples as they stand before me, it is evident that there is a rather sudden decrease in the turbidity of the water from the Missouri shore towards the Illinois shore in the first four or five bottles, and that from there on, towards the Illinois shore the difference in turbidity are comparatively small.

GENERAL HAMLIN: Is the first station 200 feet from the Missouri shore?

3213 A. I am unable to state exactly, but if I recall, Professor Van Ornum introduced evidence yesterday upon that point.

MR. WOERNER: Yes, he gave all those distances.

THE WITNESS: My recollection is that the first sample was taken about 150 feet from the Missouri shore and that succeeding samples were taken at intervals of 400 feet in this cross-section.

MR. JEFFRIES: It would make no particular difference though, as to the exact location, so that they were taken at regular intervals clear across the stream commencing at a certain point on the Missouri shore and crossing to a certain point on the Illinois shore?

A. It undoubtedly makes a difference where the samples were collected in a cross section.

Q. But a difference as to the particular point of beginning, so that it was on the Missouri shore?

A. If it was reasonably near the Missouri shore, from a general standpoint, the difference would be slight.

Q. Mr. Whipple, I will ask you if you have prepared diagrams showing graphically these cross sections of the rivers, 3217 A. the next diagram which I have here represents the results of turbidity observations made at section C, which was a section across the Mississippi River at a point about one mile below the mouth of the Missouri River. This diagram is drawn in a similar manner to the preceding. The figures at the left of the diagram indicating turbidities according to the silica standard. The figures at the foot of the vertical columns representing stations in the cross section, station No. 1 being toward the Missouri shore and station No. 8 toward the Illinois shore. Station No. 1 itself being approximately 800 feet from the Missouri shore and the other stations being about 200 feet apart, the exact locations having been given in the testimony already by Professor Van Ornum.

Q. Now the numbers in the left hand margin represent the same thing that is represented by the same numbers or by like numbers on the exhibit which has been introduced?

A. The same as in the table already introduced, yes sir.

MR. JEFFRIES: Now we offer in evidence this diagram showing the cross sections of the Mississippi River at a point about one mile below the mouth of the Missouri River known as cross-section C, and to be known as complainant's Exhibit 49.

Q. Now you have the third diagram which you prepared from this water which was furnished you?

A. Yes sir.

Q. Now describe this third diagram?

3218 A. This diagram which I hold in my hand represents the results of turbidity observations made at Section M, being a cross section of the Mississippi River at a point about a quarter of a mile above the mouth of the Missouri River. The diagram is constructed as the previous two diagrams. The figures at the left of the diagram representing the turbidity according to the silica standard, the figures at the foot of the vertical column representing the stations in the cross-section, No. 1 being toward the Missouri shore, No. 8 being toward the Illinois shore, and the stations being about 200 feet apart. The exact locations of the stations having already been placed in evidence by Professor Van Ornum.

MR. JEFFRIES: Now we offer in evidence this diagram showing the cross-sections of the Mississippi River at a point a quarter of a mile above the mouth of the Missouri River, giving the turbidity of the water, to be known as complainant's Exhibit No. 50. G. C. WHIPPLE.

ADJOURNED until 2:00 P. M. same day, Tuesday, May 12th, 1903.

3219 Southern Hotel, St. Louis, Missouri. 2:00 P. M., Tuesday, May 12th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

MR. TODD: As to the necessity of further evidence identifying these water analyses charts, as testified to by Professor Teichmann and Messrs. Miller and Goetz and other witnesses, we will waive the necessity for any further identification of the same and will consider whether we will require the same to be admitted in evidence or not at some future time. The charts shall be subject to use by either party and will be in the custody of the Commissioner.

MR. JEFFRIES: We offer for identification the charts of water analyses referred to by witnesses Tichmann, Miller, Goetz and others, containing 117 pages, to be known as complainant's Exhibit 1 for identification.

CARL UNGAR,

Called as a witness in behalf of the complainant, being first duly sworn by the Commissioner, was examined in chief by Mr. Woerner, and testified as follows:

Q. State your name?

A. Carl Ungar.

3220 Q. Where do you reside?

A. St. Louis, Missouri.

Q. What is your business?

A. Attorney at law.

Q. Mr. Ungar, have you had occassion to make any investigations as to the typhoid statistics of any towns in the Illinois River valley lately?

A. I did.

Q. State when and what towns?

A. I left St. Louis by the instruction of the City Law Department,—on or about—the date is not very essential is it, Mr. Woerner?

Q. Not at all.

A. On or about April 7th I visited the following cities and towns.

Q. Now Mr. Unger, suppose you take them up seriatim?

A. Just as I traveled and give each town?

Q. Yes?

A. At the first place I visited was Springfield, Illinois. Do you wish to know the result there?

Q. Yes.

A. The records at Springfield were in very poor shape; I could only get three years, 1900, 1901 and 1903. My instructions were to get—

3221 Q. State what you did; never mind instructions?

A. I found that in 1900, according to the report of the Health Commissioner of the City of Springfield, there were 20 deaths form typhoid fever in that year. In 1901 there were ten; in 1902 there were 8; in 1903 there were 11, for those three months of 1903, for the first three months of the year 1903.

From Springfield I went to Bloomington. In Bloomington I found complete reports. Here is a tabulated statement; shall I read this off This I took by months first and then tabulated this for the benefit of Dr. Fuller, so that he could have them in comprehensive shape.

Q. Do I understand that you tabulated the deaths from typhoid?

A. I took the fatal cases of typhoid fever on the books of the city of Bloomington.

Q. From the official records?

A. Yes, from the official records.

Q. Give us the result of your investigations by months, and the totals by years.

A. In 1893 there were 12 deaths from typhoid fever,

1894	14
1895	15
1896	9
1897	10
1898	10

3222 In the year 1899 there were 9 deaths from typhoid fever.
1900 15
1901 9
1902 15

Q. Now Mr. Ungar, these deaths by the year, you tabulated also according to the months, did you?

A. I did.

Q. And does this paper correctly represent that tabulation?

A. It is a correct copy from their books.

Q. Of the deaths for each month?

A. Of each month. I might state here, with your permission, I was in doubt about the typhoid malaria, some are registered as typhoid malaria, and there were others disguised as ulceration of the bowels, etc., so that by taking a few typhoid malaria, they balanced, of those that were disguised. That is as near as anybody could by leaving out some and putting in others.

Q. Just give us a skeleton of what you did. This table represents the result of your investigation?

A. I went through ten years of reports.

Q. Does this table represent the result of your investigation?

A. I have so stated. Yes.

The table referred to by the witness is as follows:

3223

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902
Jany	2	1	0	0	0	2	0	1	2	2
Feby	0	0	2	0	0	1	1	1	1	0
Mch	1	2	3	1	0	1	0	0	1	1
April	1	0	1	1	0	0	0	4	0	0
May	0	0	0	0	0	0	0	0	0	0
June	0	1	0	0	1	0	1	0	0	1
July	0	1	1	0	0	1	0	1	0	2
Aug	0	1	1	2	4	2	1	3	0	0
Sept	2	1	0	0	3	1	2	1	0	1
Oct	3	3	3	3	0	0	0	2	3	1
Nov	1	3	4	0	1	1	1	2	2	3
Dec	2	1	0	2	1	1	3	0	0	4
Totals .	12	14	15	9	10	10	9	15	9	15

3224 Q. What was the next town you went to Mr. Ungar?

A. The next one was Peoria. Do you want me to make another statement except what you ask me?

Q. No sir.

A. I made some memoranda for Dr. Fuller as to the source of water.

Q. What was the town?

A. Peoria, 1893, there were 16 deaths, and in 40 or 45 cases no diseases were reported during that year.

Q. You mean the cause of the death was not given in the records?

A. Yes, and in 1894 there were ten deaths, and in 77 cases during the year 1894 no diseases was reported.

Q. You mean no cause of death was given?

A. Yes sir. In 1895 there were 36 deaths and in nine cases during the year no cause of death was reported, and in

1896 there were	13 deaths,
1897	18
1898	18
1899	12
1900	23
1901	15
1902	18

That's all I have got for Peoria, Illinois.

Q. Now what was the next town you went to?

3225 A. I will take them as I get hold of them here. The next one I have here is the city of Ottawa, Illinois:

in 1893 there were	2 deaths,
1994	5
1895	2
1896	2
1897	4
1898	4
1899	3
1900	3
1901	5
1902	2

Q. Now in this town as in the others, you also tabulated the deaths by months?

A. By months, yes sir.

Q. And these deaths appear by months as indicated on the sheet that you have in your hand?

A. Yes sir.

The paper referred to by witness, is as follows:

3226 Deaths from typhoid in City of Ottawa, Illinois.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902
Jany	0	1	1	0	0	2	0	0	0	0
Feby	0	1	0	0	1	1	0	0	0	0
Mch	0	0	0	1	1	0	0	0	0	0
April	0	0	0	0	0	0	0	0	0	0
May	0	1	0	0	0	0	0	0	0	1
June	0	0	0	0	1	1	0	0	0	0
July	0	0	0	0	0	0	0	0	1	0
Aug	0	1	0	0	0	0	1	0	0	0
Sept	0	1	0	0	1	0	0	1	0	1
Oct.	1	0	1	0	0	0	1	2	1	0
Nov	0	0	0	0	0	0	1	0	3	0
Dec	1	0	0	1	0	0	0	0	0	0
Totals .	2	5	2	2	4	4	3	3	5	2

HOWARD W. FARNSWORTH,
City Clerk.

3227 Q. What is the next town?

A. We have Decatur, Illinois. These I copied from the books of Mr. Pennywell, as City Clerk. Here is the official letterhead:

In 1893 there were 5 deaths,
1894 7
1895 2
1896 no record.
1897 2
1898 5
1899 7
1900 11
1901 5
1902 4

Q. You also tabulated these deaths monthly?

A. Yes, monthly, from the books.

Q. And that appears also as per that sheet?

A. Yes, sir.

Paper referred to by witness is as follows:

3228 Decatur, Illinois.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902

No record for 1896.

3229 Q. What is the next town?

A. Joliet, Illinois. In 1893 there were 12 deaths,

1894	14
1895	15
1896	12
1897	12
1898	15
1899	5
1900	13
1901	13
1902	21

Q. Did you also tabulate those deaths monthly, as per that sheet?

A. I took them monthly as per this sheet. There is a note on this paper: "Population. Water supply obtained through wells. No water pumped direct from the river."

Paper referred to is as follows:

3230 Deaths from typhoid fever, Joliet, Ill., April 22, 1903.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902

REMARKS:

Population, 1900, 29,353,
1890, 23,264,

Water supply obtained through wells, no water pumped direct from river (Des Plaines).

3231 Q. What was the next town?

A. Pekin, Illinois. I found the reports very incomplete. Dr. Millman gave me all the help he could. 1900 is the first one I have got. In 1900 there were two deaths; in 1901 there was one death and in 1902 two deaths. It has a population of 8,400. The records for 1902 are in very bad shape. In 1902 the total number of deaths was 102, from all causes. I put that down as a comparative statement. Here I have Elgin, Illinois. In 1893 there were eight deaths, in 1894 there were 3 deaths, and in 1895 there were 5 deaths, and in 1896 there were 14 deaths. In 1897, during this year, not one case of typhoid fever was reported. In 1898 there were four deaths and in 1899 there were five death; in 1900 there were 15 deaths and in 1901, 15, and in 1902, 8 deaths.

Q. You also tabulated those for Pekin, Illinois, monthly, according to the sheet you have?

A. Yes, sir.

The paper referring to Pekin, Illinois, is as follows:

3232 Pekin, Illinois.

1903.

Jan. 0
Feb. 0
M'ch. 0
1902—total 2 deaths,
1901—total 1 death,
1900—total 2 deaths.
1902 total number of deaths 102.
Population: 1900—8420
1890—6347

Records up to 1902 in very bad shape.

Q. You also tabulated those for Elgin monthly, according to the sheet you have?

A. Yes, but in this case I had to go through a pile of stubs they had, and I bought the young lady a box of candy for helping me.

The paper referred to is as follows:

3233 Elgin, Illinois.

	1893	1894	1895	1896	1897	1898	1899	1900	1901	1902
Jan'y ...	1	1	0	0	0	0	0	0	0	2
Feb'y ..	0	0	0	5	0	0	0	1	0	2
M'ch ...	0	0	0	2	0	0	0	0	1	0
Ap'l	3	0	1	2	0	1	0	1	1	1
May	0	0	0	0	0	0	0	2	0	0
June ...	0	1	0	0	0	0	0	0	0	0
July	1	0	0	2	0	0	0	0	1	0
Aug.	1	0	0	0	0	0	3	1	2	1
Sept. ...	0	0	1	2	0	0	0	5	5	0
Oct.	0	1	2	1	0	3	1	3	2	1
Nov.	2	0	0	0	0	0	1	2	1	0
Dec.	0	0	1	0	0	0	0	[illegible]	2	1
Totals.	8	3	5	14	0	4	5	15	15	8

During 1897 not *one* case of typhoid fever reported.

3234 Q. Give us the next town?

A. Aurora, Illinois. They hadn't any records worth speaking of, but the Health Commissioner, McDonald, furnished me the following information from his records:

In 1893 there were 6 deaths,
" 1894 " 12 "
" 1895 " 19 "
" 1896 " 10 "
" 1897 " 5 "
" 1898 " 10 "
" 1899 " 4 "
" 1900 " 17 "
" 1901 " 11 "
" 1902 " 7 "

In the year 1895, there were 105 cases of typhoid fever reported, of which 19 were fatal. He explained to me the reason, if you gentlemen want to know. This is not tabulated by months except in a few instances. I couldn't get it.

I had a report from Havana, Illinois. I couldn't get them tabulated by the month; I took what I could get by the year:

In 1893 there were 3 deaths,
" 1894 " 7 "
" 1895 " 2 "
" 1896 " 5 "
Then there is no report until
In 1901 there was 1 death,
" 1902 " were 2 "

Q. Any other towns?

A. I am expecting a report from Jacksonville, where I
found the courthouse closed when I was there. I sent
3235 the county clerk his fee for writing it up for me, but it
has not arrived. That's all I have got.

Q. Now, Mr. Ungar, can you tell us what the water supply is of these respective towns?

A. Some of those I cannot give you very explicitly, because I sent the maps to the doctor at New York. I don't see it here.

(Question withdrawn.)

Q. Did you make these examinations of the records yourself, Mr. Ungar?

A. Invariably, with the exception of Ottawa, where I didn't find the clerk in, but he certified to it.

Q. Where is that certification?

A. Here (referring to the Ottawa paper.)

Q. In every other case you made the examination yourself?

A. Yes, sir.

Q. When you say it is certified, what do you mean?

A. Signed by the clerk and sent to me by the clerk. I went to LaSalle, but I don't see any report here.

Q. Now, Mr. Ungar, so far as the other towns are concerned, you examined the records yourself?

A. Yes, sir.

Q. You say that the result of your investigations as to LaSalle appears as per the sheet which you sent to George W. Fuller in New York?

A. Yes, Jacksonville and LaSalle are the two reports which are missing yet.

3236 JUDGE SPRINGER: We are perfectly willing that Jacksonville and LaSalle should be put into the record at this point without recalling the witness; the same as if he had testified to them.

MR. WOERNER: Mr. Ungar, are you able to state the population of these towns according to the census?

A. I thought I had the book, the Health Commissioner's report. That's where I got them. I can state them approximately.

CROSS-EXAMINATION, by Judge Johns.

Q. Did you make up some statistics from typhoid fever, typhoid malaria and typhus fever at Bloomington and strike an average?

A. There was one place; I think it was Elgin, where I noticed they had ulceration of the bowels, malignant ulceration of the bowels, etc., and I asked a doctor about it. There were some months where there were suspiciously few typhoid fever cases. Of course this was hearsay evidence I am giving you now, but you asked for it.

Q. I asked you if you made up in these tables from Bloomington some cases of typhoid fever which do not appear on the records in Bloomington, as typhoid fever?

A. No, sir; but I took some typhoid malaria, and a few, one or two, which were marked typhoid malaria, being in doubt whether the were typhoid or not.

Q. And you added them in as typhoid deaths?

3237 A. Yes, sir; typhoid malaria. I found two cases of intestinal ulceration. You see in the whole year 1897 there wasn't a single report.

Q. Did you add those two cases in as typhoid fever?

A. No, sir, but I made a memorandum here if you notice.

Q. Well, in what town did you add in some cases which were not reported as typhoid fever, among the number of deaths, and how many did you add in?

A. I was in doubt in several towns whether typhoid malaria was typhoid fever.

Q. Well, when you were in doubt as to whether it was a death from typhoid fever or not, what did you do with the case?

A. I left them out; I didn't report them.

MR. JEFFRIES: For instance, you took all the cases of typhoid malaria?

A. No, I didn't take all of them. I might have taken in a town one or two before I got to thinking about it. Wherever I saw typhoid I put it down. Where I was writing I had to write them very quickly. I couldn't stay very long, and when I saw tphoid, I put it down, but in some of the other towns I scrutinized it closely and I found that perhaps during the year, one, two or three were typhoid malaria, and when my attention was called to it I left them out. I want to qualify that statement I made before. In the city of Elgin, where I made the little memorandum there. It says "Intestinal ulceration." I asked one of the doctors if that couldn't possibly be typhoid. He said it might be disguised typhoid. In one whole year there wasn't a single case reported. That's the reason I investigated that closer than anything else.

CARL UNGAR.

Adjourned until 10:00 a. m., following day, May 13, 1903.

3238 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Wednesday, May 13, 1903.

Parties met pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

WILLIAM H. GETZ,

Re-called for further examination in behalf of the complainant, testified as follows:

DIRECT EXAMINATION, By Mr. Jeffries.

Q. What is your full name?

A. William H. Getz.

Q. You have been sworn in this case before, have you Mr. Getz?

A. I have.

Q. I will ask you to look at these several sheets of paper and state what they are.

A. This is a table of percentages of the Missouri and Mississippi river water at the intake of the St. Louis waterworks. These calculations are based upon the daily estimation of total solids in samples collected at Bellefontaine, the intake and at Hartford, covering a period from January 23rd to October 11, 1900.

3239 Q. Who prepared them?

A. Those were prepared by Mr. Miller and myself.

Q. Personally?

A. Yes sir.

Q. From what did you prepare them?

A. These were prepared from the daily estimations of the total solids in the water from the samples at those three points.

Q. And from the tabulated sheets which were identified by you and Mr. Miller during your former examination?

A. Yes sir, these figures were taken from those sheets.

Q. Now what do those tables show?

GENERAL HAMLIN: That is objected to. Are these the Teichmann tables?

MR. JEFFRIES: Yes sir.

GENERAL HAMLIN: And they have not been introduced?

MR. JEFFRIES: It is for you people to say whether they are to be introduced in evidence, they have been identified and offered as complainant's Exhibit 1 for identification.

GENERAL HAMLIN: All right.

Q. MR. JEFFRIES: What do they show?

A. Well, from these results of the total solids we figured the percentage of water from each river which entered the intake for every day during this period.

Q. Now I will ask you to state the column on the sheets which shows the percentage of the respective waters that
3240 enter the intake?

MR. TODD: Does that show the Missouri and Mississippi?

MR. JEFFRIES: Yes sir.

MR. TODD: It is confined to those two rivers?

MR. JEFFRIES: Yes.

THE WITNESS: Take these columns in order on the sheet—

Q. What does the first column represent?

A. The first column gives the date on which the sample was collected.

Q. What does the second column represent?

A. The second column gives the total solids in the sample collected at Fort Bellefontaine on each day.

Q. On the respective days?

A. Yes sir.

Q. And the third column?

A. Gives the same results for the intake.

Q. What do you mean by the intake?

A. Of the samples taken at the intake tower of the St. Louis waterworks.

Q. And the fourth column?

A. Is of the Mississippi river at Hartford.

Q. And the fifth column?

A. The fifth column is merely a combination of the first and third and gives the difference between the total solids at Bellefontaine and at Hartford.

3241 Q. Now what does the sixth column mean?

A. The sixth column gives the difference between the total solids at the intake and at Hartford. These were used for figuring the percentages.

Q. Now what does the seventh column represent?

A. The seventh column is the percentage of Missouri river water at the intake on that day—on each particular day.

And the eighth column is the percentage of Mississippi river water at the intake.

Q. What do the pencil marks and the figures on the right hand margin represent?

A. The pencil marks are merely averages of these daily percentages for the different months.

Q. Those pencil marks are on the right hand margin and at the side of the eighth column?

A. Yes sir.

Q. The right hand side of the eighth column?

A. Yes sir.

MR. JEFFRIES: Now we offer these sheets in evidence, which table, as testified to by the witness, is in words and figures as follows:

(Table will be found in testimony of this witness given May 30, 1903.)

3242 GENERAL HAMLIN: As I understand, this witness is testifying to percentages based upon certain tables. Now that is right, isn't it Mr. Getz?

A. Yes sir.

Q. I say these tables are based upon certain tables?

A. They are taken from the same results that appear in these tables.

Q. I know, but how do you make the calculation?

A. From the records of the total solids results for those different days.

Q. Well then those all appear in some table?

A. They all appear in some table, yes.

Q. What tables are they?

A. It is that large number of tables, sheets and charts, etc., that were in here yesterday.

Q. Well those were tables simply on the question of the mixing of the waters?

A. This table is. Those tables cover the total results.

GENERAL HAMLIN: These calculations you have introduced now, and that he is testifying about, are simply upon the question of the per cent of the different river waters that is to be found at the intake?

MR. JEFFRIES: No, it gives the amount of total solids, and from the amount of total solids he deducts the percentage of the water of the two rivers going into the intake.

3243 GENERAL HAMLIN: What is your purpose in introducing that?

MR. JEFFRIES: For the purpose of showing the mixture of the water.

GENERAL HAMLIN: Now then, there ought to be in the record that portion of these tables upon which these calculations were made.

MR. JEFFRIES: Those table are with the Commissioner.

CROSS EXAMINATION, By Judge Johns.

Q. On the table from which table was prepared, are there any statements as to the stages of the Mississippi or the Missouri river, or the gauge?

A. My recollection is that there were, yes sir.

Q. Why did you not put those stages in?

A. No sir, on the charts that were made, the gauges were put, but there were no numerical figures put on the sheets that these were taken from.

Q. Where were the stages of the river or the gauge at the time this table was made? Were they before you for the purposes of assisting in this calculation in any way?

A. I don't think so; there was no need of them.

Q. And there was no necessity of them for the purpose of calculating these percentages?

A. No sir.

3244 Q. So when this table of percentages shows that on the 7th of February that the percentage of Mississippi river water in the intake was 100 and the percentage of the Missouri river was zero, there is no intimation as to the state of the gauge of the two rivers at that time?

A. Nothing on that table, no sir.

Q. Was there anything of that kind upon any table from which you made a calculation?

A. It was put on the charts, but not in the tables.

Q. In what charts?

A. On those charts that have been exhibited, I believe—the charts that were made covering these periods—the charts made of the weekly averages.

Q. You testified to the tables containing the results of the chemical analyses of water?

A. Yes sir.

Q. Made at the St. Louis laboratory?

A. Yes sir.

Q. Were there on those tables any statements as to the gauge of the river?

A. No sir.

Q. Then to what charts do you refer?

A. Those curves as we call them, the curves that were plotted from those tables; they were plotted in colored inks on cross sections.

3245 Q. And the state of the river as shown by the gauges was on none of those charts?

A. It was on one of those simply as being interesting to know in that connection, but there were no deductions drawn in this table from the gauge of the river.

Q. Did you prepare a chart on which there was a statement of the gauge of the river in connection with any curves that have been testified to here?

A. My recollection is that we did, yes sir.

Q. Well, as it is not on any chart which we have so far introduced in evidence, I would like to have you produce that one.

A. (No answer.)

Q. How does it happen that in Febraary, 1900, you have here only 16 days?

A. Those were the only samples available during that month.

Q. And the only ones analyzed during the month?

A. The only ones that were analyzed for that particular determination.

Q. There were others analyzed for other determinations?

A. I don't know whether there were or not.

Q. Do you know whether or not on each and every one of these tables that you and Mr. Miller have identified, there was for each day in each month in which an examination of water by chemistry was made, a determniation of solids?

A. There was occasional times when samples could not be
3246 collected on account of the ice in the river, or for some
such reason as that. There was an occasional sample that was broken, I believe. Of course in that case there was no record.

Q. Do you know now whether in February there were samples analyzed from the 17th to the 28th inclusive?

A. I don't remember those dates. The table there shows the dates on which those samples were analyzed.

Q. Were there times when the determination was not made for solids when chemical determinations were made for other elements?

A. I think the total solids were always determined.

Q. Do you know whether or not the tables in which you figured up an average for February, there was a determination of solids from the 16th to the 28th of February, 1900?

A. There was if it is shown on the table, yes.

Q. It is not shown on this table. Do you know whether there was on the table from which this was prepared?

A. That includes everything shown on the tables from which it was prepared.

Q. Take the month of July, 1900, in which it appears that the average of the percentage of Mississippi river water at the intake averaged 7.73; do you know anything about the stage of the Mississippi and the Missouri river relatively at that time?

A. I don't personally at present know. We did, I think,
3247 collect the records of the stages of the rivers; but these
calculations do not depend in any way on the stage of the river.

MR. JEFFRIES: They may, however, have some effect on the results?

A. They do affect these results; but there was no use made of them in the calculations.

GENERAL HAMLIN: You have offered the table. I object on the part of the state of Illinois for the reason that the table is not relevant testimony unless the complainant offers to follow it up with proof of the rain-fall, or conditions that might have obtained, or did obtain on the lower Illinois river, on the Mississippi or the Missouri rivers at the time these calculations and analyses were made.

GENERAL CROW: In reply to that, the State of Missouri suggests that that objection is to go to the credibility of the testimony and not as to its relevancy or competency, but that at the proper time we will offer such statistics on the question of rain-fall and water gauges in the Missouri, Mississippi and Illinois rivers, as we think proper to offer.

CROSS-EXAMINATION, By Mr. Todd.

Q. Mr. Getz, where was the data from which these percentages were figured, taken from?

A. Well, I explained all that before. It was taken from 3248 the original note-books first and collected on to these charts or on the tables, and then it was taken from there for this special purpose. It is one of the determinations that were made on all these samples, and they were taken and repeated here on this table and the percentages were calculated from those. This table is strictly the chemical results.

Q. Were these figures taken from the tables that have been marked here as complainant's Exhibit 1 for identification?

A. They were.

Q. Who took these figures off of those tables?

A. Mr. Miller and myself.

Q. What part of this table did you take off, of these sheets known as complainant's Exhibit 1 for identification?

A. Well, as to which particular numbers I took I could not testify; we worked together on that.

Q. Did you ever compare the data that appears here upon this paper, with the data on Exhibit 1 for identification to ascertain whether the same were correct?

A. We compared our work, our copy of the table which we made. I didn't sit down to the typewriter and write the table, but the copy of the table which we made in our own writing was compared with the chart—with the sheets.

Q. And was this typewritten copy compared with the copy that was in your own writing?

3249 A. Not by me it wasn't.

Q. Do you know by whom?

A. I don't know who did that.

Q. Are you able to say that the data upon this table which has been offered in evidence, contained the same data that is in Exhibit 1 for identification?

A. Well, I can't answer for any clerical mistakes that might have been made in copying that. I didn't take the typewritten work and check it with the table I made out, but the table from which this was copied has been checked with those sheets.

Q. Did you check the table from which this table was copied, with the sheets?

A. I did, yes.

Q. And found it correct?

A. And found it correct.

CROSS-EXAMINATION, By Judge Johns.

Q. When you made these figures as to solids, you took them for the Missouri river at Bellefontaine?

A. Yes sir.

Q. And for the Mississippi river at Hartford?

A. Yes sir.

Q. Did you make the calculation for total solids or for solids in suspension or solids in solution?

3250 A. Total solids.

MR. TODD: How were these percentages calculated?

A. Well, there is always considerable variation or nearly always considerable variation in the total solids as found in the Missouri river at Bellefontaine, and those found in the Mississippi river at Hartford, and the total solids at the Intake of the St. Louis waterworks was found to lie between those two, or approximately the same as either one of them, and by taking the difference in the total solids in the two rivers at those places, and interpolating the value of the total solids found at the Intake, we find the percentage of the two rivers, which is represented by the mixture.

CROSS-EXAMINATION, By Judge Springer.

Q. I see from this table that you have presented, that the proportion of waters from the Mississippi river for the month of January, 1900, in the St. Louis Intake is put down at 25.75?

A. That 25.75 represents the average for all the samples we had during that month. It is simply an average for these separate days during the month of January, 1900.

Q. What does this number, then, represent?

A. That represents the average of the daily samples, which
would be considered as the average amount of Mississippi
3251 river water entering the Intake during that period, about
seven or eight days.

Q. Now this average amount of water from the Mississippi river that entered the Intake during those days in January, which are here noted, simply means an average which you have reached by estimating the total solids which you found in the waters of the two rivers, one at Bellefontaine, and the other at Hartford?

A. That is the average of those daily percentages, yes.

Q. The average as ascertained by the total solids?

A. By the total solids, yes. It simply consists in adding up the percentages for that number of days and dividing by the number of days.

Q. Now, if during that time there should have been a considerable rain-fall above Bellefontaine in the Missouri river, with no corresponding rain-fall at Alton or up the Missis- river, without any appreciable or perceptible increase of the volume of the water, there would have been a great increase in the total solids, would there not?

A. You mean no increase in the Mississippi and considerable increase in the Missouri?

Q. Yes, suppose that there was no perceptible increase really in the volume of water, but an increase in the total solids would appear, from a rain-fall above—

3252 A. Yes sir.

Q. There would have been a difference in the total solids?

A. Yes.

Q. Then the correctness of this map so far as determining the quantity of water which flowed into the intake from the respective streams would depend, then, to some degree upon the conditions of the weather along the line of the respective streams above the place where the samples were taken?

A. That is all taken into account in the samples themselves, as they are collected. We made no deductions on that account.

Q. You made no deductions on that account?

A. It doesn't influence our results, although it influences them before we get the sample.

Q. It influences the quantity of total solids, but would not to a corresponding degree influence the quantity of water; is that right?

A. That is possible.

Q. Then the condition of the weather would have something to do with the quantity of water, irrespective of the question of solids, is that right?

A. Well, I don't know that the weather would have anything to do with it.

Q. The rain-fall?

A. Well, they draw a certain amount of water through the St. Louis intake—

3253 Q. You don't seem to understand—I mean that the percentage of solids would be determined in a great measure upon the condition of the immediately preceding rain-fall in the respective rivers?

A. Yes sir.

Q. Whereas the volume of water might not itself be materially different?

A. Yes sir.

Q. Then, if there was then, a the time of this first determination, a larger stage of water in the Missouri river than is normal and a lower one in the Mississippi than normal, the question of the gauge of the two streams would have considerable to do with determining the amount of the water that actually went in from each stream, to the intake?

A. It does affect it, yes sir.

Q. So that to make this calculation accurate, it should have been taken into consideration—both these other factors, should it not?

A. No sir, the accuracy of the table does not depend upon it at all.

Q. For the accuracy of the table of percentages, it is not, but the actual amount of water that went into the intake would be determined in a great measure by these other factors, would it not?

3254 A. Well, the water goes into the intake of a certain quality. We know that it is a mixture usually of these two rivers. Now we can determine by taking a sample of water of those two rivers exactly just which one appears in the mixture. Now rain-falls and such things would affect that mixture the percentages.

Q. Without affecting the quantity of water?

A. But that is all taken account of in the analysis itself.

Q. I understand this analysis is based upon the actual quantity of solids which you found in the samples of water examined. Those solids were fixed quantities so far as you are concerned?

A. Yes sir.

Q. And they were variable only as the weather might vary, but you were not running with the weather, you were taking the samples as you found them, is that right?

A. Taking them as we found them, yes sir.

Q. If the weather and the stages of the river were the same at both these places, would not the averages for each period always be the same?

A. I don't know.

Q. What?

A. I don't think you could bring about exactly identical conditions.

Q. Well I am not asking whether you can do it or not,
3255 I am supposing that it was so. Suppose that you assume that the stage of the rivers—of both rivers, was the same during a given period of time covered by these tables, and that

the rain-fall was the same during all this period; then would not your averages for each period be the same for total solids?

A. If all the conditions affecting those were the same, the conditions would be the same.

Q. The fact that at one time during one month for instance the average would be 25.75 and the next month would be 40.67, and for another month 60.29, and so on,—they are variations which can only be explained from the different stages of the river and the different conditions of the weather along the line of the rivers above the place where the samples were taken?

A. Yes sir.

RE-DIRECT EXAMINATION, By Mr. Jeffries.

Q. Now Mr. Getz, along the line of the questions propounded to you by Judge Springer, state what effect the fact of a flood in the Missouri river and a comparatively low water stage in the Mississippi river would have with reference to the correctness of arriving at the proportionate amounts or relative amounts of the two waters going into the intake?

A. It would have absolutely no effect.

3256 Q. Then the variation referred to by Judge Springer refers simply to the amounts of the respective waters that go into the Intake by means of the change in volume of water of the respective rivers, and not with reference to the correctness of your determinations?

A. Yes sir.

Q. It doesn't interfere with the correctness of the determinations?

A. No sir, it has no effect. We have the three samples. One of them is a mixture of the other two. Now we don't care how the mud got into either one of them; it is there. As to whether it is due from heavy rain-fall or there has been a drought, and so on, that has nothing to do with it. We have the two rivers before they get to the intake; before they are mixed, and then we have the mixture, after they come together, which is entirely independent of any conditions which produce those different amounts of total solids.

3257 GEORGE C. WHIPPLE,

Re-called for further direct examination by Mr. Jeffries, testified as follows:

Q. Mr. Whipple, have you visited the Chain of Rocks and made yourself personally familiar with that portion of the waterworks plant of the city of St. Louis which is located at that point?

A. Yes sir.

Q. What is the approximate distance from the Missouri shore to the Intake tower of the St. Louis waterworks?

A. About 1,500 feet.

Q. What is the position of the Intake tower at the Chain of Rocks with reference to the channel of the Mississippi river?

A. The Intake tower of the St. Louis waterworks at the Chain of Rocks is located a few hundred feet to the west of the channel of the Mississippi river at that point.

GENERAL CROW: Do you mean to say it is only a few hundred feet west of the channel of the Mississippi river—the Intake?

A. Yes sir.

MR. JEFFRIES: Do you mean the channel or the center of the channel?

A. That would depend upon just the definition of the term "channel." When I used that word in that sentence, I meant the center of the channel of the river, that is, the central thread of the main channel of the stream. 3258

Q. What is the approximate distance from the Intake tower at the Chain of Rocks to the mouth of the Missouri river?

A. About six miles.

Q. State the general features of the Mississippi river with regard to the curves and directions of flow, between the mouth of the Missouri and the Intake tower at the Chain of Rocks?

A. From personal observation I know that the Mississippi river before it reaches the Intake tower of the waterworks, curves to the westward, but I cannot describe that curve in detail without referring to the Government chart, or to some chart upon which that curve is shown. If that chart can be shown to me I could explain it more in detail.

Q. Now in that connection I want to ask you what are the general features of the river with regard to curves and directions of flow between the mouth of the Missouri river and the Intake tower at the Chain of rocks, which you can explain from the chart?

A. Kindly read that once more?

Q. What are the general features of the Mississippi river with regard to the curves and direction of flow between the mouth of the Missouri river and the Intake tower at the Chain of Rocks?

A. The chart is right here.

3259 Q. I say you can explain it from the chart.

A. Yes sir. From this chart, which shows a section of the Mississippi river and which has been offered as complainant's Exhibit No. 44, I find that the Mississippi river just above the point where the Missouri river enters it, is flowing in a direction slightly west of south. Further, that the direction of the eastern bank of the stream continues to be the same down to the lower part of the mouth of the Missouri river. At about that point the Mississippi river—

GENERAL HAMLIN: Will you allow me to suggest that when you can, when you speak about "that point," that you locate the point.

MR. WOERNER: He said about the lower point of the mouth of the Missouri.

A. (Continuing.) At the lower point of the mouth of the Missouri, the Mississippi river, which there contains both the waters of the upper Mississippi river and the Missouri river, turns to the westward and flows in a southwest direction. About one mile below the lower point where the Missouri river enters, the river flows for a short distance almost westward. During the next mile of flow, the right bank of the river has a direction slightly north of west. Below this point there is a second bend in the river, and the direction of the right bank becomes somewhat south of west, and then this curvature continues, gradually increasing, towards a southerly direction until at a point about a mile and a half—about two

3260

miles I would say above the Intake of the Chain of Rocks, the western bank of the stream has a direction which is generally north and south. For that mile of the stream just above the Intake of the waterworks the direction of the right bank of the stream is somewhat west of south. Going back to the lower point of the mouth of the Missouri river I find that the left bank of the stream is practically parallel with the right bank, for about 1½ miles. Below that point the left bank of the stream is a southwest direction and barring a slight indentation about a half mile below this point, that is, a southwesterly direction, that is a generally southwesterly direction, continues to a point opposite the intake of the St. Louis waterworks. At a point about 1½ miles below the lowest point of the mouth of the Missouri river, the river broadens and does not contract again to the distance just found at the lowest point of the mouth of the Missouri river before it reaches the Intake of the waterworks at the Chain of Rocks.

Q. Now, Mr. Whipple, from your general knowledge of stream flows, what is the effect of those curves upon the mixing of the Mississippi and Missouri river waters?

A. From my general knowledge of the subject of rivers and the effect of curves upon the currents of those rivers, it is 3261 my opinion that this curve which I have described, in the Mississippi river between the mouth of the Missouri river and the Intake of the St. Louis waterworks would tend to allow, or would increase, or would be favorable to the mixture of the waters which come down the Mississippi river and the Missouri river.

Q. At what points now would that mixture take place the most rapidly?

Question withdrawn.

Q. Independent of sanitary conditions, what are the general characteristic features of the Missouri river water and the Mississippi river water at the mouth of the former, or at the mouth of the Missouri?

A. *Judged from the samples of water which I have received from the Missouri river at Bellefontaine—I will not say from Bellefontaine, but from the section shown upon the chart which I have before me, from section B, and from section M in

the Mississippi river upon this chart, I should say that the water in the Missouri river is much more muddy than the water in the Mississippi river; that is, that it contains very much larger amounts of suspended matter, and by referring to the analyses which I have made I can show that by figures as well as by this general statement. For example, the average turbidity of the three samples collected at section B on
3262 April 12, 1903, was 1493 parts per million. This average figure being the numerical average of the turbidity observations which I have already placed in evidence. The average of results of the turbidity observations made upon the samples collected on April 10, 1903, was 127 parts per million.

MR. TODD: Where was that, doctor?

A. At section M.

MR. JEFFRIES: That was across what river?

A. Section M being a cross-section across the Mississippi river just above the point where the Missouri river enters the Mississippi.

These figures bear out the general statement which I made, that the water in the Missouri river is much more muddy and contains more suspended matter than the water in the Mississippi river. From observations which I made upon the samples collected during the months of October and November, 1901, in the Missouri river at Bellefontaine, and in the Mississippi river at Alton, I found the same general fact to be true, and from an inspection of the analyses made under the direction of the city chemist and which have been recorded upon certain sheets and placed in evidence as complainant's Exhibit 1 for identification, and consisting of 117 sheets, I found that this also bore out my statement in regard to the greater amount of suspended matter in the water of the Missouri river than in that of
3263 the Mississippi river above the mouth of the Missouri.

From observations which I made upon the color of samples of water from the Missouri river at Bellefontaine, and from the Mississippi river at Alton during the months of October and November, 1901, I found that the water of the Mississippi river at Alton was more highly colored than the water of the Missouri river at Bellefontaine, and in using this term color, I refer not to any substances in suspension, but rather to substances in solution.

From an inspection of the sheets which contain the results of chemical analysis of the samples of water from the Missouri river above its mouth and from the Mississippi river at points above the mouth of the Missouri, I have observed that the amount of chlorine in the Missouri river was generally higher than the amount of chlorine in the Mississippi river above the mouth of the Missouri.

From the same sheets I also observed that ordinarily the amount of alkalinity in the Missouri river at Bellefontaine, was higher than the alkalinity in the waters of the Mississippi river above the mouth of the Missouri.

Q. Assuming that the Mississippi water above the mouth of the Missouri contains certain forms of vegetable life which can be distinctly identified by well defined characteristics, and further assuming that the Missouri river water at that
3264 time contained no such species of vegetable life, and that
those forms of life are present in water drawn through the Intake tower at the Chain of Rocks, I will ask you to state what that shows as to the presence of Mississippi water in the Intake tower?

A. If I should find the organisms which you mention in the water of the Mississippi river above the mouth of the Missouri, and if at the same time these organisms were absent from the water of the Missouri river itself, and if at the same time I should find them in the water of the Intake tower of the St. Louis waterworks at the Chain of Rocks; it is my judgment that these organisms found at the Intake tower of the St. Louis waterworks came from the water of the Mississippi river above the mouth of the Missouri river and that they were borne thither by the water of the Mississippi river above the mouth of the Missouri.

Q. Assuming that at times the water of the Mississippi river above the Missouri contains very little mud, and that the water of the Missouri river at the same time is highly charged with mud, and further assuming that the water taken through the intake tower at the Chain of Rocks, contains an amount of mud intermediate in quantity between those of the two rivers before they unite, state what in your opinion that shows with regard to the mixing of the waters of the two rivers?

3265 GENERAL HAMLIN: That is objected to on the ground that it does not assume all of the facts testified to and appearing in the record, and all the conditions necessary to be assumed before an expert can answer such a question.

THE WITNESS: Under the assumptions just made, it would be my opinion that the water found at the intake tower of the St. Louis waterworks, at the Chain of Rocks, was not entirely water derived from the Missouri river nor water entirely derived from the Mississippi river above the mouth of the Missouri, but was a mixture of the two waters.

MR. JEFFRIES: Mr. Whipple, I hand you a table containing a transcript of the quantities of the total solid matter in the Missouri river at Bellefontaine, and the Mississippi river at Hartford, and the water at the Intake, which is a table read in evidence by the witness Getz, and ask you to explain the table, and state whether or not the results as to the quantity of water of the respective rivers entering the Intake at the Chain of Rocks, are determined by that table?

GENERAL HAMLIN: That is objected to on the ground that this witness is an expert; that he did not make the table, and did not make the table from which deductions in the table now in the expert's hands were made.

MR. JEFFRIES: It is not introduced for the purpose of showing that the total number of solids is correct.

3266 MR. TODD: I also object to it on the ground that the table speaks for itself. That the question is answered by the table itself.

THE WITNESS: I find that this table which you show me contains eight columns of typewritten figures; in the first column there is a series of dates beginning with January 24, 1900, and extending to October 10, 1900.

In the second column there is a series of figures under the caption "Bellefontaine," which, from the heading at the top of the table, I infer to represent the total solids in the samples collected at Bellefontaine on the respective dates.

In the third column I find a series of figures which I understand from the general heading of the table to represent the total solids in the samples collected at the intake of the St. Louis waterworks on the respective dates, and in the next column I find a series of figures which I understand represent the same information upon samples taken from the Mississippi river at Hartford.

In the fifth column is a series of figures which I understand from the caption, gives the results obtained by subtracting the figures in the fourth column from those in the first column.

In the sixth column is a series of figures which I understand is obtained by subtracting the figures in the fourth column from those in the third column.

3267 In the seventh column is a table of figures which I understand gives the percentage of Missouri water in the intake of the St. Louis waterworks, presumably calculated from the figures in the previous columns.

In the last column there is a series of typewritten figures giving the percentage of Mississippi River water at the intake of the St. Louis waterworks also calculated from the figures in the previous column.

(Question repeated)

A. In looking over this table I find that in general the total solids found in the samples at the intake were intermediate in amount between those found in the Mississippi River at Hartford and in the Missouri River at Bellefontaine, and it is my opinion that it is possible from the figures given to calculate approximately the relative amounts of the water of the Missouri River and of the Mississippi River above the mouth of the Missouri present in the water at the intake of the St. Louis waterworks. I understand that the percentages obtained in the last two columns, were obtained from the information given in the previous columns. Does that sufficiently answer your question, Mr. Jeffries?

Q. Yes.

GENERAL HAMLIN: Before you ask another question, I move to exclude the answer to that question for the reason that the witness does not undertake to say that he made the

3268 table or that he made the table from which this table was made, or that he has himself examined the samples or made any analyses of the waters at the points mentioned, and his answer is simply to bolster up a table made by someone else and not by him.

MR. JEFFRIES: Assuming that the table before you contains the correct number of total solids in the waters of the two rivers, state the degree of reliability of the percentage of the waters of the two rivers calculated from these total solids that would enter the intake at the chain of rocks?

GENERAL HAMLIN: That is objected to upon the ground that the reliability of this table does not depend upon any expert knowledge that this witness has, nor from any actual knowledge he has derived from the original tables from which this table is made.

THE WITNESS: It is my opinion that if the figures given in this table represent the total solids in the water of the Mississippi River at Hartford and the water of the Missouri River at Bellefontaine, and the water of the intake of the St. Louis waterworks at the chain of rocks, if these figures are accurate representations of the total solids in the samples collected, and if the samples collected fairly represent the waters of the streams at the points named, then the calculations made by using these figures in obtaining the percentage of water of the Missouri River and of the Mississippi River above the mouth of the
3269 Missouri, in the water of the intake of the St. Louis waterworks, are reliable.

GENERAL HAMLIN: I move to exclude that answer for the reasons that are apparent in the answer given by the witness.

ADJOURNED until 2:00 P. M. same day, May 13, 1903.

3270 Southern Hotel, St. Louis, Missouri. 2:00 p. m., Wednesday, May 13th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE resumed the stand for further direct examination, by Mr. Jeffries, and testified as follows:

Q. Mr. Whipple, state whether or not you made any calculations of the percentage of the waters of the two rivers, to-wit, the Missouri and the Mississippi, entering the Intake at the Chain of Rocks, from the samples of water that were furnished you, and about which you testified previously in this case; if so, state what those perentages are?

A. I made no such calculation of the percentage of the Mississippi River water in the Intake at the Chain of Rocks, but I made calculations showing the percentage of Mississippi River water at stations 4 and 5 on cross-section I, the results of which were submitted the day before yesterday, and shown on complainant's Exhibit 44, or rather the location of which is shown on complainant's Exhibit 44.

3271 Q. Where is cross section "I"?

A. Cross section I was located as shown by the diagram mentioned before, about one-quarter of a mile above the Intake Tower of the St. Louis Waterworks at the Chain of Rocks, and from this diagram it is apparent that the inlet tower of the Chain of Rocks—that the distance of the inlet tower of the Chain of Rocks from the Missouri shore, is the same distance as from the Missouri shore to some point in the cross section, between stations 4 and 5. In making the calculation to obtain the percentage of Mississippi river water at point 4 in the cross section I, I assumed that the turbidity of the Missouri river was represented by the average of the turbidity observations in the three samples collected at cross-section B, cross-section B being shown on the diagram before me. I found that the average of the three turbidity observations mentioned were 1493. I assume further that the turbidity of the water in the Mississippi river was represented by the average of the turbidity observations made upon samples collected at cross secton M as shown on the map at a point about a quarter of a mile above the mouth of the Missouri river. I assume further that the turbidity of the water at point 4 in section I was represented by the average of the turbidity observations made upon the three samples collected at different depths at that point. This average turbidity was found to be 263.

3272 These figures showed that the average turbidity of the water at point 4 in secion I, was intermediate between the figures showing the turbidity of the water of the Missouri River at section B, and the turbidity of the water of the Mississippi river water at section M.

GENERAL HAMLIN: Did you give the turbidity of the water of section M?

A. I thought I did. The average of the turbidity observations made at section M was 127.

MR. JEFFRIES: Go ahead with your answer.

A. Using these three average figures for the turbidities of sections B and M and the point 4 in section I, I calculated that the percentage of Mississippi river water at point 4 in section I, was 90 per cent.

I made a similar calculation to find the per cent. of Mississippi river water at point 5 in section I, using the same average turbidities for section B and section M, and using for the average turbidity of the water at section I, the average of the turbidity observations made at three different depths, that is the average turbidity at point 5, section I, being 152. From these three figures I calculated that the percentage of Mississippi river water at the point 5 in section I was about 97 per cent.

Q. Now, state those per cents again so that we can get 3273 them clearly in the record, of points 4 and 5 of the respective waters?

A. My calculation showed that the percentage of Mississippi river water which was present at point 4 in section I, was about 90 per cent., and that the percentage of the Mississippi river water at point 5 in the same section, is about 97 per cent.

Q. Now, those were calculations of the percentage of the two rivers that appear in the Mississippi at that point at that time?

A. Yes, sir.

Q. When were those samples gathered?

A. The samples at section B were collected on April 12th, 1903; the samples at section I were collected on April 10th, 1903, and the samples in section M were collected on April 10th, 1903.

Q. Now, Mr. Whipple, assuming that when the waters of the two rivers, the Mississippi and the Missouri, unite or connect at their junction, that there is no mingling of the waters with each other as they flow down the stream; what would be the character of the water as shown in the cross section across the Mississippi river at the Chain of Rocks or at a point a short distance above the Chain of Rocks, or at a point in the river as shown by section I, on complainant's Exhibit 44?

A. On the assumption to which you have referred I should expect to find under those conditions, that in crossing the river from the Missouri shore to the Mississippi shore, there would be a sharp line of demarkation separating the water of the Missouri river on the west shore from the water of the Mississippi river on the east shore, and that the position of this line would be determined by the relative volumes of these two streams, the Mississippi river and the Missouri river, and the cross section of the river at that point. 3274

Q. Have any of your examinations or analyses of these waters indicated such results?

A. No examinations which I have made, have shown that such a sharp line of demarkation existed, and that can be illustrated by referring to certain exhibits which have already been presented.

Q. What physical exhibit would you refer to?

A. It was shown by the samples of water collected at twelve points on the section I, numbered from 1 to 12, beginning on the Missouri shore, and which have all been exhibited in this room. The fact is also shown by a certain diagram which has been presented, illustrating the turbidity of the water at this section.

Q. Mr. Whipple, which one of the ingredients mentioned by you this morning, permits the portion of the amount of the two river waters, at the Chain of Rocks, to be determined the most accurately, and why? 3275

A. In comparing the general character of the waters of the Missouri river and the Mississippi river above the mouth of the Missouri this morning, I referred to the presence of suspended matter in the two waters, to the presence of chlorine, to the presence of alkalinity, to the turbidity, to the color and to the total solids. Of these various parts of the analysis of water, it is my opinion that the relative percentages of the waters of the Mississippi river and the Missouri river at the Intake at the Chain of Rocks, can be most reliably determined from the total solids, for the reason that the differences between the total solids of the two rivers is ordinarily fully as great as shown by the other parts of the analysis and for the reason that this determination is in general somewhat more accurate than the others. The determination can be made, for instance, by a comparison of the chlorines in the waters of the two streams, but there is not as great a difference—greater relative difference between the chlorines in the water of the Missouri river and the Mississippi river than is ordinarily found in the case of the total solids. The same is true for the alkalinity and the same is true for the color.

Q. Are you familiar with the published reports showing the population and natural residents upon the watershed of the Missouri river, of the upper Mississippi above the Chain
3276 of Rocks, and of the upper Illinois river, and their tributaries?

A. Yes, sir; I am familiar with certain reports showing those facts and with the reports of the United States census for 1900, which give those facts.

Q. When considering cities having a population of 25,000 or more according to the census of 1890, what percentage of increase to the population naturally resident upon the watershed of the Mississippi, at the Chain of Rocks, is caused by the Sanitary District of Chicago diverting its sewage into the Illinois river and becoming thereby tributary to the Mississippi?

GENERAL HAMLIN: That is objected to on the ground that it is not a proper basis of estimation upon which to base a proper conclusion as to this subject matter by an expert, and the further objection that the testimony is not relevant to the issue in hearing, made by the bill and answer.

THE WITNESS: Speaking generally the population is about double.

MR. JEFFRIES: Now, what do you mean by the word "double" when you used it in connection with your answer to the previous question?

A. I mean that there is a certain population naturally tributary or situated upon the watershed of the Missouri river and the Mississippi river above the Intake, and the Illi-
3277 nois river, exclusive of the population of Chicago, and that if we add to this natural population upon these three watersheds, that would more than double that population.

Q. That is by considering cities having over 25,000 inhabitants?

A. On the assumption mentioned in your question as I understand it, considering only cities which have a population of 25,000 and over.

Q. Considering cities having a population of 4,000 or over, how large a percentage of increase in population tributary to the Mississippi above the Intake Tower of the St. Louis Waterworks at the Chain of Rocks, is caused by the Chicago Drainage Canal discharging the sewage of Chicago into the Mississippi river by means of the canal and the Illinois river?

GENERAL HAMLIN: That is objected to on the ground that it is not based upon a proper estimation that is resident upon the Mississippi and its tributaries above the Chain of Rocks.

THE WITNESS: This percentage of increase is about 63 per cent.

Q. MR. JEFFRIES: What do you mean by 63 per cent?

A. I mean to say that if you consider the population of cities which have more than 4,000 population, situated upon the watersheds of the Missouri river, the Mississippi River
3278 and the Illinois river above the Chain of Rocks, but not including the population of Chicago, and if we add to this population the population of Chicago, we should increase the populations as mentioned, by about 63 per cent.

Q. As a general proposition is it customary for sanitarians to consider that the amount of sewage pollution in a stream may be approximately estimated by taking the sum of the population of the towns on its watersheds having a population of 4,000 residents or over, and if so, why?

MR: TODD: I object to the question on the ground that what is customary among sanitarians does not bind the defendants in this case.

THE WITNESS: There is such a custom among sanitarians. There is this custom among sanitarians, that when it is desired to determine the amount of pollution, sewage pollution which exists in a stream at any point, at any certain point, to consider the population dwelling upon the watershed above that point in cities which have 4,000 or more inhabitants, and for this general reason we take it the country over. It has been found that in general, communities which have more than 4,000 inhabitants, are ordinarily supplied with such public improvements as public water supplies and sewerage systems, while in general those communities which have less than 4,000 people are not ordinarily so supplied. It is recognized that this is an arbitrary dividing line but for practical scientific
3279 purposes, it is believed to be a reliable method of estimating the pollution of a stream, or the relative pollution of different streams.

MR. TODD: I move to strike out the answer on the ground that we are dealing with facts and not with customs.

MR. JEFFRIES: What mode or means did you adopt as a sanitary expert in making those calculations?

A. I have adopted the same means.

Q. What is the distance by river from the mouth of the Missouri to the mouth of the Illinois?

A. I think it is about 23 miles.

Q. I will ask you if it is possible by reason of analytical results to determine the amount of mixing of the Illinois and Mississippi waters during their flow from Grafton to Hartford, and if you have made any such determination, to state your results?

A. I believe that it is possible by analytical means, to determine the percentage of Illinois River water which is present in the water of the Mississippi river at Hartford, for example. I have also made such a calculation in order to determine the percentage of Illinois River water at Alton as well as at Hartford. I made these calculations from the analyses shown upon the sheets which I hold in my hand and which form a part of complainant's Exhibit 1 for identification.

3280 Upon this first sheet there are given the results of the determinations of nitrites. In five samples of water collected daily from October 30th, 1901, to November 29th, 1901, at five points in a cross section of the Mississippi River at Alton, and these points being marked, A, B, C, D and E.

Sample A being taken at the Missouri shore.

Sample E being taken at the Illinois shore, and the other points intermediate between them.

The same sheet also shows the results of the determinations of chlorides, at the same points and on the same dates.

This other sheet which I hold in my hand gives the results of chemical analyses among which I find the determinations of chlorines, made upon samples collected in the Illinois River at Grafton daily, between October 30th, and November the 29th, 1901.

The sheet also gives determinations of the nitrites from the same samples. From this next sheet I gather the results of chemical analyses of samples collected in the Mississippi River at Grafton, among which I find determinations for the amount of chlorine upon daily samples collected between October 29th and November 29th, 1901, and also the determination of nitrites for the same samples.

3281 From the determinations mentioned, I have obtained the following average figures for the period mentioned: At the cross section at Alton, Station A, contained 5.2 parts of chlorine, and .002 parts of nitrite.

Station B contained 6.8 parts of chlorine, and .005 parts of nitrites.

Station C contained 8.7 parts of chlorine and .009 parts of nitrites.

Station D contained 9.7 parts of chlorine and .0105 parts of nitrites.

Station E contained 10 parts of chlorine and .0115 parts of nitrites.

JUDGE JOHNS: Those are the averages for that time?

A. Those are the average figures at the five points mentioned.

GENERAL HAMLIN: Now for the purpose of making a motion here I should like to ask the witness a question. Professor, you are using certain tables there. Are those tables made by you?

A. These tables, complainant's Exhibit 1 for identification?

Q. Yes?

A. No sir.

Q. Then you are giving results from tables that you have not made?

A. Yes sir.

MR. JEFFRIES: The witness stated that they were sheets taken from complainant's Exhibit 1 for identification.

GENERAL HAMLIN: I move to exclude the answer as to the results obtained, as they are not expert's state-
3282 ments, but are statements of a fact determined from tables not made by the witness.

THE WITNESS: I have averaged the figures given upon the table which shows the determinations of the nitrites and chlorines, at five stations, at a cross section at Hartford, and from those I obtained the following results:

At station A the chlorine was 6.8 parts per million, and the nitrites .006.

At station B the chlorine was 7.1 and the nitrites .006.

At station C the chlorine was 8 parts per million, and the nitrites were .008.

At station D the chlorine was 8.8 parts and the nitrites .009.

At station E. the chlorine was 9.1 parts and the nitrites .010.

I found—I have not at hand at this moment the averages obtained for the Illinois River at Grafton, or the Mississippi River at Grafton, which averages were used in the calculations now to be described, but I can produce these averages later.

From these average figures, I have calculated the percentage of the Illinois river water at the five points in the cross-section of the Mississippi River at Alton, and obtained
3283 the following results:

At station A I obtained 7.8 per cent of Illinois River water.

At station B I obtained 7.7.

At station C 29.3 per cent.

At station D 35.4 per cent.

At station E 37.2 per cent.

While at Hartford I obtained the following percentage figures for the per cent of the Illinois River water at the different points:

At station A	17.17
B	19.5
C	25.
D	29.8
E	31.7

I have also plotted these results on a diagram which I have and which I submit (Hands paper to counsel).

Q. What is this?

A. This is a diagram which shows graphically the results, the average amounts of nifrites and chlorines at the cross-sections at Alton and Hartford, across the Mississippi river, for the period from October 30 to November 4th, from the period of October 30th to November 29th, in the case of the Alton cross section and from November 4th to November 30th, in the case of the Hartford cross section.

3284 It also gives in the lower portion of the diagram, a graphical illustration of the per cent of the Illinois River water at the two cross-sections.

Q. Who prepared that?

A. This a blue print which was made from a tracing, the tracing being made from an original which I personally prepared.

Q. That is an exact copy of the original which you prepared?

A. This is an exact copy of my original.

Q. And a correct copy?

A. Yes sir.

GENERAL HAMLIN: Now I want to enter this motion to exclude this answer on the ground that this testimony is based upon data, analyses and tables not prepared by the witness who has testified upon this point as an expert. This answer is simply the results obtained from data or tables or analyses not made by him and is not expert testimony.

MR. JEFFRIES: From what did you prepare the chart?

A. From the average figures showing nitrites and chlorines at the various points in the two cross sections, which average figures I obtained from the sheets giving daily analyses and which sheets have been placed in evidence and form a part of
complainant's Exhibit 1 for identification, and from the
3285 figures which I obtained, using these average results to
show the percentage of the Illinois River water at the various points in the two cross-sections.

MR. JEFFRIES: Now we offer this diagram in evidence as complainant's Exhibit 51. Received and marked by the Commissioner.

GENERAL HAMLIN: I object to the diagram for the reason given in the motion to exclude the answer to the former question.

MR. JEFFRIES: Are you personally familiar with the present condition of the Chicago River and its several branches and forks?

A. Yes, I have personally inspected the territory you mentioned, and I am familiar with reports and maps, etc., which show the general situation of the places you mention.

Q. Mr. Whipple, assuming that at a certain time lake Michigan water contained an organism called synedra pulchella sub prolongata variety, and that this plant is not contained at corresponding times in any of the branches tributary to the Illinois river nor in the upper Mississippi water at Grafton, nor in the Missouri river water, and further assuming that this plant was found at a corresponding time in the water at the intake tower at St. Louis, what in your opinion does that show?

MR. TODD: I object to the question on the ground that the assumptions have not been established in the evidence, especially as to the Missouri river.

3286 THE WITNESS: It would show that this synedra pulchella variety sub prolongata was not derived from the water of the Missouri River or from the water of the Mississippi river above Grafton, or from the tributaries of the Illinois River, but that it came from Lake Michigan and was borne thither by the water from Lake Michigan.

Q. The correct name of that organism is what? I do not know that I have got it exactly right.

A. Synedra pulchella variety sub prolongata.

Q. Assuming that the Lake Michigan water contained at a certain time a certain organism known as tabellaria, and that this plant is not contained at a corresponding time in any of the branches tributary to the Illinois River, nor in the upper Mississippi River at Grafton, nor in the Missouri River water, and further assuming that this plant was found at a corresponding time in the water coming from the settling basins of the St. Louis Waterworks at the chain of rocks, what does this show?

A. It would show that the tabellaria found in the settling basins of the waterworks at the chain of rocks, did not come from the water of the Missouri river nor from the water of the Mississippi river above Grafton, nor from the water of the tributaries of the Illinois river, but did come from the water of Lake Michigan and was borne to the settling basins above mentioned, by the waters of Lake Michigan.

3287 Q. What in your opinion is the duration of life of the germ of typhoid fever in natural water?

A. When the germs of typhoid fever are put into natural waters they will continue to live for several months, though in gradually decreasing numbers.

Q. Assuming that the sewage and lake water passing from the Chicago River into the drainage canal, reaches the Mississippi river at the chain of rocks in ten and one-half days, will the typhoid fever germs coming from the sewers in Chicago, survive the passage through the Chicago River, the Chicago Drainage Canal, the Des Plaines River and the Illinois river, to St. Louis?

GENERAL HAMLIN: I object to that question upon the ground that this assumption is based upon a condition which does not exist, namely, that the water is in a natural condition in the Chicago River and in the Drainage Canal and below Peoria, after the sewage of Peoria has entered into the river.

A. From what I know about the life of the typhoid fever bacillus in the water, and from my knowledge of the conditions which exist between the Chicago drainage canal and the intake of the waterworks of St. Louis at the chain of rocks, it is my opinion that if typhoid fever germs exist in the sewage of Chicago, they will survive the passage down the Chicago Drainage canal and to the intake tower of the St. Louis waterworks at the chain of rocks under existing conditions.

3288 GENERAL HAMLIN: I move to exclude the answer on the ground,—or rather so much of the answer on the ground that it is not responsive to the question and on the ground that the witness has not yet shown any personal knowledge, by anything shown in the answer as being responsive to the question, and anything responsive is not based upon any evidence that he has yet given, on the question of typhoid fever germs.

3289 Q. You testified here a moment ago that you were personally acquainted with the conditions of the Chicago River and the Drainage Canal, did you not?

A. Yes sir.

Q. State those conditions, Mr. Whipple, as you saw them?

A. Do you mean to give the entire situation?

Q. Yes.

A. About one month ago I made a personal inspection of the Chicago River and the Chicago drainage canal and Des Plaines River, as far as Joliet. I saw the point where the Chicago River naturally drains into Lake Michigan; I saw the north branch of the Chicago River, the south branch of the Chicago River, the south fork of the south branch, and what I believe is called the west fork of the south branch of the Chicago River. I saw the point where the Chicago Drainage canal begins; I saw the beginning of the old Illinois and Michigan canal; I saw the terminus of the Chicago Drainage Canal at Lockport, and inspected the Bear Trap Dam at that point; I saw the Illinois and Michigan Canal at that point—at Lockport, and noted the place where it could discharge into the Des Plaines River, and I saw the Des Plaines River at Joliet and the dam at that place.

Q. Now then, from your personal observation to which you

have just testified, and assuming that the sewage and
3290 lake water passing from the Chicago River into the drainage canal, reaches the Mississippi at the chain of rocks, in ten and one half days, will typhoid fever germs, coming from the sewers in Chicago, survive the passage through the Chicago Drainage Canal, the Des Plaines river and Illinois River to St. Louis?

GENERAL HAMLIN: That is objected to upon the ground that the witness has not yet shown that he has made any examination upon which an opinion could be based, by the witness, and the further objection that as an expert he has not yet been asked the facts touching this question, that are in the record, upon which that is all material facts upon which he can base an opinion as an expert, such as an opinion should be based upon.

MR. TODD: I object to it on the ground that the assumption of time does not include the height of water in the Des Plaines and Illinois Rivers at the time,—the time of ten and one-half days.

A. It is my belief that they will.

GENERAL HAMLIN: I move to exclude the answer for the reasons given in the objection to the question.

Q. MR. JEFFRIES: Assuming that at times of flood conditions in the Illinois River, the period of passage of Chicago sewage to the chain of rocks at St. Louis is eight days,—is it, or is it not true that that would enable a greater percentage of the typhoid fever germs to survive the passage to the chain of rocks at St. Louis?

3291 GENERAL HAMLIN: The same objection as made to the former question.

A. Under the conditions assumed it is my judgment that a great proportion of typhoid fever germs would reach the intake of the St. Louis water works from the Chicago drainage canal when the time of transit was 8 days than when the time of transit was 10½ days.

GENERAL HAMLIN: I move to exclude the answer of the witness on the same grounds as previously stated.

MR. JEFFRIES: Q. From your general knowledge of typhoid fever epidemics state whether there are cases on record where such epidemics have occurred where the evidence shows the typhoid fever germs considered to have caused the epidemic remained in the water for at least 10½ days prior to the entrance of the water into the service pipes of the community where the epidemic prevailed?

MR. TODD: I object to the question on the ground that he has not shown that he has any knowledge on the subject of typhoid.

MR. JEFFRIES: Q. State whether or not you have any such knowledge?

Question withdrawn.

Q. Go ahead and answer the question.

(Last question read).

GENERAL HAMLIN: That is objected to on the same ground that the question does not disclose the kind of 3292 water referred to nor the conditions, and if admissible at all as a fact and not as an expert question, the record would be the best evidence,—the record showing such a condition.

MR. JEFFRIES: Go ahead and state. I will state the question again. From your general knowledge of typhoid fever epidemics, state whether there are cases on record where such epidemics have occurred, where the evidence shows that typhoid fever germs considered to have caused the epidemic remained in natural water for at least ten and one-half days prior to the entrance of the water into the service pipes of the community where the epidemic prevailed?

MR. TODD: The same objection to that question as to the other question.

A. I believe there are such cases on record.

MR. TODD: I move to strike out the answer as not responsive to the question as I believe it was asked.

Q. State the cases that are on record of this character?

MR. TODD: I object to the question on the ground that the records are the best evidence, if there are any such records.

A. The epidemic which occurred at Detroit, Michigan, and the epidemic which occured at Lawrence, Massachusetts.

JUDGE SPRINGER: What year was that?

A. I don't recollect the year.

MR. TODD: I move to strike out the answer as not being
3293 competent evidence.

MR. JEFFRIES: From your knowledge of existing conditions of the Chicago Drainage Canal as you have just testified, and of the several connecting water courses between that canal and the intake tower of the St. Louis waterworks at the chain of rocks, is it, or is it not your opinion that there exists any efficient work of artificial construction which continually insures the prevention of typhoid fever germs which may enter the Chicago drainage canal, from reaching the intake of the St. Louis waterworks at the chain of rocks?

GENERAL HAMLIN: That is objected to upon the ground that the witness has given no such personal knowledge, information or examination of the waters upon which he can base an answer as such a witness, and if asked as an expert, the question does not include the facts testified to in this case in this, that it does not show the amount of water discharged into the drainage canal from Lake Michigan nor the amount of water at an average season of the year discharged into the Illinois river through its tributaries and does not include the waters of the Mississippi above Grafton, and does not include the waters of the Missouri river.

MR. TODD: I object to the question as to its form.

A. It is my opinion that no such work of artificial construction exists as to bring about the result mentioned.

3294 Q. Assuming that between January 17th, 1900, and December 31st, 1902, as compared with the period from 1895 to 1899, inclusive, there had been no increase on an average in the number of deaths from typhoid fever in those cities situated upon the Missouri river, upon the Mississippi river above Grafton, and upon the Illinois river and its branches, exclusive of the Chicago Drainage Canal, and further assuming that the typhoid fever death rate in the City of St. Louis had increased about 54 per cent on an average during this period, over the previous period mentioned, and further assuming that there was no substantial change in the manner of treatment of the water supply of St. Louis, and assuming further that since January 17th, 1900, a large part of the sewage of Chicago has been passed through the drainage canal and thence into the Des Plaines River, the Illinois River, the Mississippi River, and into the intake, and assuming further that some of the water of the Mississippi river would contain a certain amount of Illinois river water at the intake of the waterworks at the chain of rocks;—state what if anything, in your opinion the Chicago sewage from the drainage canal had to do with the increased typhoid death rate in St. Louis?

GENERAL HAMLIN: That is objected to upon the ground that the question itself discloses that the facts attempted to be stated are not stated with any sufficient degree of 3295 certainty and the further objection that the question is not based upon all of the material testimony introduced in evidence, as appears of record in this case so far.

MR. TODD: I object to it on the ground that the time, namely, two years prior to December, 1900, is not a fair assumption of the typhoid conditions which existed in 1899 in the City of St. Louis, and for the further reason that there is no evidence to show that the Illinois river water enters the intake of the St. Louis waterworks.

GENERAL HAMLIN: I would like to add a still further objection, that the record introduced in this case shows the deaths from typhoid fever in St. Louis from 1890, instead of 1895.

MR. TODD: I want to add to my objection in there, that there is no evidence to show that the sewage of Chicago enters the intake at the chain of rocks, or that the sewage that did enter, if it did enter, was Chicago sewage.

MR. JEFFRIES: Go ahead and answer the question, Mr. Whipple?

A. Under the assumption which you have mentioned, and if the conditions named are those which obtained, it is my judgment that the sewage of Chicago was the most probable cause of the increase of typhoid fever in the City of St. Louis which you mentioned.

Q. From your knowledge of existing conditions in the 3296 Chicago Drainage Canal, and of the several connecting water courses between that canal and the intake tower of the St. Louis waterworks at the chain of rocks, is it or is it not your opinion that there exists any reliable and efficient natural agencies which can continuously insure the prevention of typhoid fever germs which may enter the Chicago Drainage Canal, from reaching the intake of the St. Louis Waterworks at the chain of rocks?

A. It is my opinion that no such natural agencies exist.

Q. Assuming that 106 barrels containing 40 gallons each of the culture of bacillus prodigiosus, each cubic centimeter of the culture solution containing about one thousand million prodigiosus germs were emptied into the Chicago Drainage Canal at Lemont, and further assuming that at the time of this experiment this germ was absent in Lake Michigan water and the Illinois river water, and its tributaries; in the Mississippi river above Grafton, and in the Missouri river water, and assuming that soon afterwards some colonies of bacillus prodigiosus on several occasions were found in samples of water taken from the intake tower at the chain of rocks; what in your opinion does this show?

MR. TODD: I object to that question as it does not contain the facts as proven.

3297 MR. JOHNS: I object further on the ground that the assumption of one thousand million is at least one hundred times too small.

MR. JEFFRIES: 1,000 million per cubic centimeter.

JUDGE JOHNS: Oh, all right.

JUDGE SPRINGER: I object on the ground that the evidence on which this is based, of Dr. Ravold, did not show that several colonies were found there, but that only three distinct bacteria were found at that place.

A. Under the conditions mentioned in your question, it is my opinion that the finding of colonies of bacillus prodigiosus at the intake of the waterworks at the chain of rocks, if they were found at such a time after the introduction of the culture of prodigiosus into the Chicago Drainage Canal at Lemont, as was consistent with the time required for water to pass from the one place to the other, and if this bacillus was absent during this period from the water of the Missouri river, or from the water of the Mississippi River above Grafton, or from the water of the tributaries of the Illinois river, or from the water of Lake Michigan, it is my opinion that the origin of the bacilli found, was the culture which was introduced into the Chicago Drainage Canal.

Q. As a general proposition what is the evidence as to the relative life history of typhoid fever germs and prodigiosus germs in natural water—as a general proposition?

3298 A. To judge from experiments which I have made and from what I generally know of the subject, it is my judgment that the longevity of the two germs in natural waters is not greatly different.

Q. Assuming that the number of deaths from typhoid fever in the city of Chicago from 1895 to 1902, inclusive, have been as follows:

1895	518
1896	751
1897	437
1898	636
1899	442
1900	337
1901	509
1902	801

State from your general sanitary knowledge, the relation which exists between the dejecta of those persons dying of typhoid fever in Chicago, and the mixture of sewage and lake water entering the Chicago Drainage canal?

GENERAL HAMLIN: That is objected to on the ground that there is no proof in the record that the dejecta of typhoid fever patients has been discharged into the Lake or the sewers of Chicago.

MR. TODD: I object on the ground that there is no evi-
3299 dence to show that prior to 1900 any of the dejecta of typhoid patients entered the drainage canal, as the canal, was not opened until 1900, and the evidence prior to that time was incompetent.

A. From my general sanitary knowledge, it is my judgment that the dejecta of typhoid fever patients would enter the sewage of Chicago—

GENERAL HAMLIN: That would or does, did you say?

A. That do, I say, enter the sewers of Chicago, and that under the assumptions mentioned, that the sewage of Chicago enters the Chicago Drainage Canal, or has entered the Chicago Drainage Canal since its opening, since January 17th, 1900, it is my judgment that the dejecta from the typhoid fever patients of Chicago enters via the sewers of Chicago, the Chicago Drainage Canal, or the Chicago River, and the Chicago Drainage canal.

G. C. WHIPPLE.

ADJOURNED until 10:00 A. M., to following day, May 14th, 1903.

RECORD

The State of Missouri

vs.

The State of Illinois

and

Sanitary District of Chicago

VOL. 3

72

S.6

IN THE

Supreme Court of the United States

THE STATE OF MISSOURI
vs.
THE STATE OF ILLINOIS
and
THE SANITARY DISTRICT OF CHICAGO.

Original,
Docket No.

Before
FRANK S. BRIGHT,
Commissioner of the Supreme Court of the United States.

VOLUME 3.

A—126½

VOLUME 3.

Southern Hotel, St. Louis, Missouri.
3300 10:00 A. M., Thursday, May 14th, 1903.
Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

THE COMMISSIONER: It appearing that two of the sheets in complainant's Exhibit No. 1 for identification were inserted by mistake, they are, with consent of the defendants, withdrawn from this exhibit, and said exhibit No. 1 for identification consists of 117 pages instead of 119 pages.

GEORGE C. WHIPPLE,

Resumed the stand for further direct-examination by Attorney General Crow, and testified as follows:

GENERAL HAMLIN: Are you through with the witness, Mr. Jeffries?

GENERAL CROW: The witness wishes to put in something that he did not have with him yesterday.

Q. Go ahead Mr. Whipple, and make the corrections or additions to your testimony that you wish to.

A. In my testimony yesterday, I did not have at hand the average amount of chlorine in the water of the Illinois river above Grafton for the period between October 30, and November 29, 1901, which I used in calculating the percentage of Illinois River water at various points in a cross-section of the Mississippi River at Alton. Upon consulting my notes I find that the average figure which I used was 20.3,—this figure being an average of the results of daily chlorine determinations given upon one of the sheets in complainant's Exhibit No. 1 for identification. Neither did I have the figure for the average chlorine in the water of the Mississippi River above Grafton for the same period, and upon consulting my notes I find that the figure which I used was 3.9 parts per million of chlorines. This figure being an average of daily determinations of chlorine 3301 given upon one of the sheets in complainant's Exhibit No. 1 for identification.

GENERAL CROW: Is that all the additions you wish to make?

A. Yes sir.

GENERAL HAMLIN: I move to exclude that answer or statement. Before I do that, though, I will ask a question.

Q. These sheets that you referred to Mr. Whipple, are the sheets that were prepared by Mr. Teichmann as you understand it?

A. I don't know who prepared the sheets.

Q. Do you know who made the figures that are in the sheets and who made the analyses shown by the sheets?

A. Not from personal knowledge, no sir.

3302 Q. Do you from any information that you have?

A. I have heard the testimony of Mr. Getz yesterday, and from that testimony I understood that these sheets were prepared by him and Mr. Miller, but I don't know that from personal knowledge.

Q. The original sheets, the sheets for identification?

A. I am speaking of the sheets in complainant's Exhibit No. 1 for identification.

Q. Well, those are not the tables that were testified to yesterday by Mr. Getz, are they?

A. I think he referred to those tables in his testimony.

Q. Yes, but the tables that he had were tables that were prepared by him and Miller from the sheets, as I understand, that you are referring to. I want to see if I am right about that.

A. From these sheets.

GENERAL HAMLIN: Isn't that a fact, Mr. Jeffries?

MR. JEFFRIES: No, this testimony that he is giving now has nothing to do with those smaller sheets that Mr. Getz testified to. It is simply drawn from the contents of those larger sheets contained in complainant's Exhibit 1 for identification.

GENERAL HAMLIN: That is the way I understand it.

GENERAL CROW: Those made under the direction of the men that have heretofore testified in this case—or made by the men.

GENERAL HAMLIN: You understand that those sheets are the results of examinations made by Teichmann and Keiser?

3303 A. That is what I understand—under the direction of Dr. Teichmann.

GENERAL HAMLIN: Now I move to exclude this statement or answer on the ground that it is a mere calculation testified to by this witness based upon tables that were not prepared by him and are not the subject of expert testimony.

GENERAL CROW: The answer to the motion to strike out is that these matters have been introduced in evidence, identified and the contents sworn to and proven by the men who did the work personally.

I want to ask another question or two of Mr. Whipple before we close the examination in chief.

Q. Mr. Whipple, assuming that since January 17th, 1900, a larger amount of the sewage of Chicago has entered the Desplaines and Illinois Rivers via the Chicago Drainage Canal, than was previously the case, and assuming that water of the Illinois river containing such sewage, enters the Mississippi River and passes to the intake of the St. Louis water works at the chain of rocks, what in your opinion, is the relative safety of the St. Louis water supply at the chain of rocks in the Mississippi River before and after January 17th, 1900, with reference to its use for drinking purposes?

GENERAL HAMLIN: That is objected to upon the ground that the proofs so far offered by the complainant fails to show the facts assumed in the question. 3304

A. Upon the assumptions named in the question it is my judgment that since January 17th, 1900, the water at the intake of the St. Louis waterworks, has been relatively less safe for drinking purposes than prior to that time.

GENERAL HAMLIN: I move to exclude that answer for the reason that the facts assumed in the question are not the facts as testified to by the complainant's witnesses and the records, so far.

Q. GENERAL CROW: Mr. Whipple, what, in your opinion, is the most dangerous kind of pollution of public water supplies derived from rivers, lakes, ponds or reservoirs, with reference to the safety of these waters for drinking purposes?

A. It is my judgment that the most dangerous kinds of pollution of such water supplies, are the dejecta and urine of human beings, such as are commonly found in the sewerage systems of cities and towns.

CROSS-EXAMINATION, by General Hamlin.

Q. Mr. Whipple, I was not here when you gave the major part of your testimony. As I understand, you have qualified as a chemist and bacteriologist, have you not?

A. Yes sir.

3305 Q. Of how manys years experience?

A. Fourteen.

Q. During that time you have been located at Brooklyn, New York?

A. Part of that time I have.

Q. How long at Brooklyn?

A. Since 1897.

Q. And before that time where?

A. Before that time at Boston.

Q. Now how many analyses of the waters of the Mississippi River above Grafton, have you made?

A. I would want to refer to that sheet that I submitted.

Q. You can refer to anything you choose.

A. May I see that sheet before I answer?

Q. Yes, get anything you want.

A. You said the Mississippi River above Grafton?

Q. Yes.

A. Seven.

Q. And when did you make them?

A. Between the dates of October 16th and November 26th, 1901.

Q. Where did you receive those samples?

A. At my laboratory in Brooklyn, New York.

Q. Have you made any other analyses except those that you have now mentioned, of the waters of the Mississippi

3306 River above Grafton?

A. A number of years ago I made certain physicial tests of the water of the Mississippi at Minneapolis.

Q. (Question repeated). I am speaking of analyses. Have you or have you not?

A. I ordinarily include under the general head of water analyses, such physical tests as that of the determination of color and turbidity.

Q. Speaking from a scientific standpoint, is that correct, that those are included under the head of analysis?

A. I consider such to be the case.

Q . So that you did, some years ago, make some, what you term physical tests, at Minneapolis?

A. Yes sir.

Q. How many years ago was that—to the best of your recollection?

A. Three or four years ago.

Q. Who assisted you in making those tests in Minneapolis, anyone living there?

A. No one, no sir.

Q. Was that on the occasion of some convention that was held there?

A. Yes sir.

3307 Q. Are you acquainted with Mr. P. M. Hall, of Minneapolis, who was Commissioner of Health, for the several past years?

A. I don't remember him, no sir.

Q. Do you know the name of the City Chemist at that time?

A. I don't remember it.

Q. You did know probably at that time, did you not?

A. My impression is that I met him, but I went to the—well I am unable to say.

Q. Did you make any test for sediment at that time?

A. No sir.

Q. For ammonia?

A. No sir.

Q. Chlorides?

A. No sir.

Q. Organic matter?

A. No sir, excepting as the organic matter may be included in the color of the water.

Q. Nitrates or nitrites?

A. No sir.

Q. Or total solids?

A. No sir.

Q. What was the condition of the samples that you received in October and November, 1901, at your laboratory when they came there?

3308 A. The samples were received in bottles which had cork stoppers and which were sealed. Is that what you mean by condition?

Q. Well, whatever you mean by condition. You are a better judge of that than I am.

A. Well, I will stop there.

Q. All right. Well, did you make a chemical analysis ot those samples?

A. No sir.

Q. Did you make a bacteriological examination, or whatever you may term it?

A. No sir.

Q. None whatever?

A. No sir.

Q. How many samples, if any, did you receive from the Illinois River, yourself, above Grafton, and when?

A. I received seven samples from the Illinois River at Grafton between the dates of October 16th and November 26th, 1901. I received five samples from the Illinois River at Beardstown—

Q. No, you are not answering my question. I would like to have you limit your answers to the questions. Read the question.

(Question read).

A. Well, those samples that I have mentioned are all above Grafton.

3309 Q. Well I mean immediately above Grafton; I don't mean any other point.

A. I received seven samples from the Illinois River at Grafton between the dates of October 16th and November 26th, 1901.

Q. From whom did you receive them?

A. From one or more collectors working under the direction of Dr. Ravold.

Q. Now what condition were they in when you received them?

A. The samples were received in glass bottles which had cork stoppers, and these bottles were sealed when received.

Q. Did you make any chemical analysis of those waters?

A. No sir.

Q. Any bacteriological examination?

A. No sir.

Q. Were those all of the samples above Grafton at the mouth of the Illinois, that you ever personally examined?

A. Yes, if you mean immediately above Grafton.

Q. I do. And the ones that you have testified that you received above Grafton on the Mississippi, are the only ones that you have personally examined?

A. Immediately above?

Q. Yes, immediately above?

A. Yes sir.

3310 Q. Now you say you received some samples further up the river—the Illinois River?

A. Yes sir.

Q. What place?

A. I received some from the Illinois River at Beardstown.

Q. When?

A. In the month of November, 1901.

Q. Who sent you those?

A. One or more collectors who worked under the direction of Dr. Ravold.

Q. Who is Dr. Ravold?

A. He is a physician who resides in St. Louis.

Q. What connection has he with this case, as you understand it?

A. I understood that at the time, when these samples were sent to me he was the consulting bacteriologist of the St. Louis Health Department.

Q. You understood that these samples that you received from the Illinois River and the Mississippi River above Grafton, were received for the purpose of your making an examination so as to enable you to be a witness in this case, did you not?

A. I think nothing was said definitely about my being a witness in this case at that time.

Q. Answer the question. Read the question. (Question read).

A. No sir.

3311 Q. Didn't you expect at that time to be a witness in this case?

A. I didn't consider the matter at that time.

Q. Didn't you have reason to believe in your own mind that you would be called upon to testify in this case?

MR. JEFFRIES: Objected to as incompetent and irrelevant.

GENERAL CROW: We object to it for the further reason that it does not matter what he had reason to believe so far as this case is concerned.

A. I did not.

GENERAL HAMLIN: When did you first know that you would be called as a witness?

A. I don't remember.

Q. About when?

A. Well, within a year.

Q. That is rather indefinite, Mr. Whipple, couldn't you locate it nearer than that?

A. Perhaps I may say within half a year; I don't remember just when.

Q. How many samples did you receive and from whom and when, of the waters of the Missouri River above its mouth?

A. I received five sample between the dates of October 16th and November 21st, 1901, from sample collectors who worked under the direction of Dr. Ravold, and who collected the samples at Fort Bellefontaine.

3312 Q. Did you make any chemical analysis of those samples?

A. No sir.

Q. Did you make any bacteriological examination?

A. No sir.

Q. You regard yourself, and you are regarded, are you not, in your judgment, as an authority on the chemical analysis of waters and the bacteriological examinations of waters?

A. Yes sir.

Q. Now when did you next receive, if you did receive, any samples from the Missouri River?

A. The next samples which I received from the Missouri River were those which were collected by Professor Van Ornum on April 12th, 1903?

Q. What year?

A. 1903,—the present year.

Q. And how many samples did you receive?

A. Three.

Q. Are those the samples that you received Mr. Whipple taken at different depths of the water in the Missouri?

A. Which samples do you refer to, the last three?

Q. Yes?

A. They were all taken at a depth of ten feet.

Q. Did you make any chemical analysis of those samples?

A. No sir.

Q. Any bacteriological examination of them?

3313 A. No sir.

Q. Did you receive, and if so, when, any samples of the Mississippi River water taken above the mouth of the Missouri —immediately above the mouth of the Missouri?

A. I received the samples already mentioned and in addition eight samples collected in a cross section known as section M, and which were collected by Professor Van Ornum on April 10, 1903.

Q. Who is Professor Van Ornum?

A. I understand that he is Professor of civil engineering in the Washington University of this city.

Q. And has testified as a witness for complainant?

A. Yes sir.

Q. Did you make any chemical or bacteriological examination of those samples?

A. I did not.

Q. Does that cover all the samples that you have ever received from that point?

A. Yes sir.

Q. Now, if you received any samples of the waters of the Mississippi River above that point and between that point and the Mississippi River just below Grafton, state when and where?

A. I received six samples of water from the Mississippi River at Alton, Illinois, which were collected between October 16th and November 21st, 1901.

3314 Q. That was in 1901?

A. I am not quite through with the answer.

Q. All right. Any time that I interrupt, you stop me and straighten it out.

A. And also twelve samples of the water of the Mississippi River above Alton, collected on November 12th, 1901.

Q. That is all, is it?

A. Yes sir.

Q. Now did you make any chemical analyses or bacteriological examination of those waters—of the samples, I should say?

A. I did not.

Q. Now if you received any samples of water from any point below the mouth of the Missouri, you may state when and where?

A. I received seven samples of the water of the Mississippi River at the Illinois shore opposite the chain of rocks, which were collected between October 15th and November 29th, 1901.

Q. Who did you receive them from—while you are stating that?

A. From collectors who were working under the direction of Dr. Ravold.

I also received eleven samples from the Mississippi River just above the chain of rocks, collected on November 10, 1901.

Also seven samples of water from the Mississippi River at the intake of the St. Louis water works, at the chain of rocks which were collected between October 15th, and November 3315 29th, 1901.

I also received twenty-four samples from the Mississippi River at a cross section which has already been described as series C, just below the mouth of the Missouri River, which samples were collected by Professor Van Ornum, on April 12, 1903.

I also received 33 samples of water from a cross-section of the Mississippi River which has been described as series I, just above the intake of the St. Louis waterworks, which samples were collected by Professor Van Ornum on April 10th, 1903. Those are all the samples.

Q. Who located that cross section I?

A. I understand that Professor Van Ornum did.

Q. And it is not at the intake, is it?

A. No sir.

Q. How far above it?

A. I think about a quarter of a mile.

Q. Don't you think it would have been a fairer test to have located that cross section at the intake?

A. That would depend upon what kind of a test is meant.

Q. Well I am speaking of the tests that you made?

A. I don't think it would be a much fairer test.

Q. Well you think it would be somewhat fairer, don't you?

A. Practically not.

3316 Q. Practically not?

A. Yes.

Q. Now these samples that you have mentioned, did you make any chemical analysis of these samples?

A. No sir.

Q. Nor any bacteriological examination?

A. No sir.

Q. Now I think you have given all the samples that you have received, have you not?

A. No sir.

Q. Well now, if any others, when and where,—in the Mississippi, the Missouri or the Illinois?

A. That is all I received from the Missouri River or the Mississippi River, but I received other samples from the Illinois river.

Q. Well, let us have them and when and from whom, and where?

A. I received six samples from the Illinois River at a point three miles above Peoria, which were collected between October 16th, and November 21st, 1901 and which were sent to me by collectors who worked under the direction of Dr. Ravold.

Q. Did you make any chemical analysis of those samples?

A. I did not.

Q. Not any bacteriological examination?

A. No sir.

Q. Now go right on?

3317 A. I received no other samples in any of the three rivers which you have named.

Q. Now you have given them all?

A. Those are all of the samples which I received from the Missouri river or the Mississippi River or the Illinois river.

Q. Yes? You received some samples from the tributaries of the Illinois?

A. Yes sir.

Q. Well now, I will ask you the general question as to the samples that you have received from the tributaries of the Illinois; did you make any chemical anlaysis or bacteriological examination?

A. No sir.

Q. Have you stated all now?

A. I have stated all the samples that I received from the three rivers you named, but I have not stated what samples I received from the tributaries.

Q. But you have stated on all that you did, you didn't make either any chemical or bacteriological examination of them?

A. Yes sir. I made no chemical or bacteriological examinations of any samples mentioned.

Q. Did you receive any samples from the Drainage Canal?

A. Yes sir. I received six samples from the Chicago Drainage Canal at the Bear Trap Dam at Lockport, which were collected between the dates of October 17th and November 3318 26th, 1901.

Q. Did you make any chemical analysis or bacteriological examination of those samples?

A. No sir.

Q. Any others on the drainage canal?

A. I received four samples which were marked, Paulina Street, and which are included in this sheet marked Chicago Drainage Canal, but I understand that these were collected from the Chicago river just before it enters the Chicago Drainage Canal. These four samples were collected between November 8th and November 30th, 1901, and were received from collectors who worked under the direction of Dr. Ravold.

Q. Have you received any other samples from the drainage canal or the Chicago River?

A. No sir.

Q. Any from Lake Michigan?

A. Yes.

Q. Where?

A. I received five samples from the Lake View crib, between the dates of November 4th, and November 22nd, 1901.

I received three samples from the Carter Harrison crib between the dates of November 6th and November 15th, 1901, and two samples from the Four Mile crib on November 20th and November 27th, respectively, 1901.

3319 Q. Is that all?

A. All of which samples were received from collectors who worked under the direction of Dr. Ravold.

That is all from Lake Michigan.

Q. Now did you make any chemical analysis or bacteriological examination of those samples?

A. I did not.

Q. What examination did you make?

A. Of the last samples mentioned, or all?

Q. All?

A. I made microscopical examinations of all of the samples mentioned, except those samples which were collected by Professor Van Ornum.

Q. I don't know whether that includes the three samples that you got from the Missouri river or not. Does it?

A. It does not include the three samples collected in the Missouri River on April 12th, which were collected by Professor Van Ornum.

MR. WOERNER: What year?

A. 1903.

GENERAL HAMLIN: Now why didn't you make chemical examinations of these samples and bacteriological?

A. Because I wasn't asked to do so.

Q. You could have made these examinations very easily, could you not? 3320

A. Yes sir.

Q. Now there are two kinds of vegetable growth that you mentioned that you found in the waters of Lake Michigan that you did not find in the Missouri River. (See if I state this correctly) and the Mississippi River above Grafton, and the tributaries of the Illinois; is that right?

A. I don't think I made that statement.

Q. Then just state it, without hunting up your testimony. I want to get started right on it.

A. I stated that there were two microscopic organisms,—vegetable plants, if you choose—

Q. Perhaps you had better name them right there?

A. Synedra and tabellaria, which were especially characteristic of Lake Michigan water, but not of the waters of the Missouri River or the Mississippi River above Grafton or the tributaries of the Illinois river.

Q. Right there now, Mr. Whipple, do I understand you to mean that those two do not exist in the waters of the Mississippi above Grafton,—those micro-organisms?

A. No sir.

Q. You don't mean that?

A. No sir, I don't mean that.

Q. Then they might be found, so far as you know, in the
3321 Mississippi River above the mouth of the Illinois?

A. They certainly might.

Q. And do you mean to say that they cannot be found or do not exist in the waters of the Missouri River?

A. No sir.

Q. Do you mean to be understood as saying that they do not exist nor cannot be found, in the tributaries of the Illinois?

A. No sir.

Q. Where do you generally find these micro-organisms especially?

A. You refer to these two?

Q. Yes, I refer to those two?

A. They are usually found in the waters of lakes, ponds or reservoirs.

Q. Now do you know how many lakes, if any, are situated on the Illinois River between Lockport and Grafton?

A. I don't know.

Q. You have no knowledge on that point, have you?

A. No personal knowledge, no sir.

Q .And you have no knowledge of whether or not there are any lakes or ponds that connect with the Mississippi River above Grafton?

A. No personal knowledge that I can recall at the moment.

Q. If there were lakes on the Illinois River between Lock-

3322 port and Grafton that connect with the Illinois River, you would expect to find those micro-organisms, wouldn't you?

A. They might be found there.

Q. Well, wouldn't it be reasonable to suppose that they would be found there?

A. At times, yes sir.

Q. And the same is true of the Missouri River and of the Mississippi river, isn't it, under the same conditions?

A. Yes sir.

Q. Now how much experience have you had as a chemist?

A. I have had charge of Mt. Prospect laboratory in the Brooklyn Water Department since 1897.

Q. Isn't that considered one of the principal laboatories in the country?

A. Yes sir.

Q. And how much experience have you had as a bacteriologist?

A. I have had charge of the laboratory mentioned and I have carried on bacteriological examinations in Boston from 1889 to 1897, and I have carried them on since that time up to the present date.

Q. Have you ever made any examinations of the waters of the Mississippi River below St. Louis?

A. No sir.

Q. Never examined it at New Orleans?

3323 A. Not to my recollection.

Q. Mr. Whipple, how familiar are you with the waterworks system of St. Louis?

A. I have seen the plant at chain of rocks, I have seen the pumping station at Baden; I have ridden along the conduit connecting the two. I have seen from the train the settling basins at Bissell's Point.

Q. Do you know how many settling basins they have here?

A. There are two plants.

Q. You don't know the number?

A. No sir.

GENERAL HAMLIN: How many are there General Crow?

GENERAL CROW: I really can't say; there are six I believe. There are six at the upper works and two at Bissell's point.

THE WITNESS: There are four at Bissell's Point and six at the chain of rocks.

GENERAL HAMLIN: That would make ten altogether?

A. Yes, counting each particular tank as a basin.

Q. What is the purposeof settling basins, for what purpose are they used?

A. To get rid of the mud.

Q. Any other purpose?

A. To get rid of the suspended mater in the water also.

3324 Q. What effect does it have upon the water itself?

A. What effect does it have?

Q. Yes, the use of settling basins.

A. It makes the water clearer.

Q. Anything else?

A. It makes the water freer from suspended matter.

Q. Does it purify the water?

A. Yes, to some extent, by the removal of matter in suspension.

Q. What do you consider the principal elements in the purification of water?

A. The removal of those substances which would render water impure.

Q. Has dilution anything to do with it?

A. If the water is diluted with another water which is purer than it is, it makes that first water purer.

Q. Has sedimentation anything to do with it?

A. With purification?

Q. Yes.

A. Yes, sedimentation ordinarily makes the water purer.

Q. Are dilution and sedimentation regarded by scientists and sanitarians as the two important elements in the purification of water?

A. They are regarded as two important elements.

3325 Q. Aren't they regarded by the authorities on the subject of sanitation and purification of water, as the principal elements?

A. No sir, I wouldn't say the principal elements.

Q. Would you say they were regarded as important elements?

A. In certain cases they are regarded as important elements.

Q. In most cities that use means for purification, aren' settling basins used extensively?

A. Yes, in cases where the original water contains larg amounts of suspended matter which would settle out during th process of sedimentation.

Q. What do you mean by natural water?

A. Any water found in nature.

Q. Is that the sense you used it in when the questions wer asked you yesterday as an expert?

A. I don't remember the particular question to which yo refer.

Q. You were asked some questions regarding sewage being discharged into natural water?

A. Yes, I meant in that sense. That is the sense in whic I intended it.

Q. And that is the sense in which you have used the ter during your entire examination is it, by the complainant?

A. Yes sir.

Q. Who prepared the expert questions which were aske you yesterday. Did you prepare any of them?

3326 GENERAL CROW: I don't like to object to that, but will say for your information without calling on the wi ness for it, that myself, Mr. Fuller, Mr. Whipple and the othe gentlemen jointly got those questions up.

GENERAL HAMLIN: I don't regard it as improper at a for Mr. Whipple to have perpared the questions.

GENERAL CROW: I don't regard it improper for anyo to have prepared the questions.

GENERAL HAMLIN: Nor I; only I want the fact.

GENERAL CROW: You have the facts now. It can g into the record as my statement. If you insist on the witne answering it I will not object, but I do not think it is right, wit all due respect to you.

GENERAL HAMLIN: I think it is proper, General,—not impugning any motive of Mr. Whipple's which I expressly deny, because Mr. Whipple in his testimony has been fair on the basis on which he has given it, but as to the character of the questions submitted to him, that's all.

Q. I will ask you if you prepared them?

A. I didn't prepare them all.

Q. Did you prepare those that refer to the typhoid fever?

A. I may have assisted, but I don't think I prepared them all.

Q. You did prepare some of them.

A. Some of them I did not prepare.

3327 Q. You did prepare some of them?

A. Some of them I did not prepare.

Q. And some you did, did you?

A. In some of them I assisted.

Q. Did you prepare any of them yourself absolutely, all of them or any one entire question?

A. I don't think I did.

Q. When you testified to the per cent of chlorine found in the Mississippi above Grafton—you did testify to that, didn't you?

A. Not expressed in percentage.

Q. I thought you gave the percentage there?

A. Not the percentage of the chlorine.

Q. What was it?

A. I used an average figure in my testimony taken from the sheets of complainant's exhibit 1 for identification which gave the amount of chlorine in parts per million.

Q. And you took the average, did you?

A. Yes sir.

Q. And then you took the average of chlorine in the Illinois River above Grafton, as I remember it?

A. Yes sir.

Q. And then you took the average chlorine at what point below Grafton?

3328 A. At five points in the cross section of the Mississippi River at Alton and Hartford.

Q. Now for what purpose did you use that, for the purpose of showing the mixing of the waters of the Illinois and the Mississippi?

A. Yes sir.

Q. Why didn't you adopt the same plan of using the solids instead of the chlorines?

A. Because there were no determinations of the total solids on those sheets.

Q. There were not?

A. No sir.

Q. There was no determination of solids in the Illinois River above Grafton?

A. There were such determinations there.

Q. Why—but none above Grafton in the Mississippi?

A. There were such determinations there.

Q. Why couldn't you use that?

A. Because there were no corresponding determinations at the five points in the two cross-sections at Alton and Hartford?

A. There were no determination of solids at all for those points.

A. No sir.

Q. On those tables?

3329 A. No sir, not upon the tables which I referred to.

GENERAL CROW: The solids were not determined in the cross-sections.

GENERAL HAMLIN: Wasn't there a determination of the solids at Alton and Hartford?

GEGNERAL CROW: Not in the cross sections.

GENERAL HAMLIN: I don't mean the cross section. My recollection is from Teichmann's testimony, that's all. Do yor know Mr. Whipple?

A. I don't recollect.

Q. Well, if there had been determinations of solids at those points wouldn't it have been a better and more correct test than to use the chlorines?

A. Yes, if there had been a greater difference between the total solids in the Illinois River at Grafton and the Mississippi

River above Grafton than was the case with the chlorines.

Q. Well do you select the greatest difference as the best test, without regard to anything else?

A. Well, that is one of the reasons for selecting these, but the accuracy of the determination should also be considered in picking out the ones which should give the best results.

Q. You stated yesterday, I think, to Mr. Jeffries, that the best test, that is, the most reliable test, is the test made with the solids?

3330 A. I consider it to be such for the particular case which is being discussed. I wouldn't lay that down as a universal proposition.

Q. Well, do you consider that one standard of tests is to be adopted at one place and another standard at another place, and another standard at another, where you are dealing with the same waters and the same rivers practically, at the same points or nearly so?

A. It might be so.

Q. How would you consider that?

A. It would depend upon each individual case.

Q. Well the individual case here is the condition of the water at the intake of St. Louis, isn't it?

A. The individual case which was discussed yesterday where I made the statement that the total solids was the best test, was the case where we compared the waters of the Mississippi river and those of the Missouri river with the water of the intake at the chain of rocks.

Q. Don't you think, Mr. Whipple, it would be a fairer test, if you had sufficient data, to employ the same tests from the Mississippi river at Grafton, the Illinois at Grafton and the river between Grafton and the mouth of the Missouri, and the mouth of the Missouri to the intake?

A. It would depend upon what those data showed.

3331 Q. Please answer this question by yes or no.

GENERAL CROW: I desire to interpose an objection to counsel asking a question and instructing the witness what to answer, and submit the witness has a right to answer the question in any manner he sees proper, that is responsive to the question.

A. The question is not sufficiently intelligible for me to answer Yes or No.

Q. GENERAL HAMLIN: Doesn't the question embrace "that if you had sufficient data?"

A. The question is still sufficiently unintelligible for me to answer "Yes" or "No."

Q. Do you say as an expert that that question is not sufficiently intelligible to you as such an expert, that you can answer "Yes" or "No," and then make such explanation hereafter as you choose to make?

A. The question is sufficiently not intelligible for me to answer Yes or No?

Q. Can you answer Yes or No to that question?

A. Not without explanation.

Q. How far below the mouth of the Illinois river at Grafton do you say that there is any mixing of the Illinois with the Mississippi River?

A. I believe that such a mixing of the Illinois River with the waters of the Mississippi was evident at Alton.

3332 Q. How far is that from Grafton?

A. I don't recollect; I should have to look it up in some references.

GENERAL HAMLIN: Does anybody know here?

GENERAL CROW: Somewhere from twelve to eighteen miles, I think about sixteen miles.

Q. Assuming that it is fifteen miles, you may state if you know, the condition of the banks, the right and left bank between Grafton and Alton.

GENERAL CROW: The condition with reference to what, General?

GENERAL HAMLIN: I mean how the banks are with reference to the river?

A. I have never seen the river in that region, but from my recollection of the charts I believe the banks to be very nearly parallel with each other and very nearly in a straight line, barring slight irregularities. I am speaking now in very general terms and I should want to consult the chart before giving it in detail.

Q. You are not prepared to say then whether there are any curves in these banks between Grafton and Alton, or not?

A. My recollection is that there are no important curves.

Q. You say that you think there is a mixing of the waters of the Illinois and Mississippi at Alton?

A. I think that the Illinois river water mixes with the water of the Mississippi by the time it reaches Alton, to
3333 some extent.

Q. To some extent?

A. To some extent, yes sir.

Q. And that you understand to be about fifteen miles away from where the rivers unite?

A. As I said, I don't recollect exactly, but in a general way I believe that is about the fact.

Q. How far is it from the mouth of the Missouri River to the St. Louis intake?

A. I think it is about six miles.

Q. In your examination you stated: "From my general knowledge of the subject of rivers and the effect of curves on the currents of these rivers, it is my opinion that this curve which I have described (referring to a curve on the map or chart which you had in front of you) in the Mississippi river, between the mouth of the Missouri river and the intake of the St. Louis waterworks would tend to allow or would increase, or would be favorable to the mixture of the waters which come down the Mississippi river and the Missouri river." Now which one of those statements do you wish to adopt, "Would tend to allow, or would increase, or would be favorable?"

A. I think they are all applicable.

Q. That they mean the same?

A. No sir, I don't think they mean the same, but I think
3334 they are all applicable.

Q. Then you wish to stand by all of them?

A. Yes sir.

Q. Now at what point would that mixture you speak of, take place the most rapidly?

A. I should say in that part of the curve where the central thread of the main channel crosses from the position near the left bank to a position near the right bank.

Q. Where is that point?

A. I should have to refer to that map to give that.

Q. Locate it if possible, with reference to the mouth of the Missouri river by distance.

GENERAL CROW: Do you want to add that to your question?

GENERAL HAMLIN: That is proper to add to that question.

A. When I used the word "point" I did not mean a geometrical point; I meant a place.

Q. Well, where is that place?

A. That place is from one to two and a half miles below the southern point of the mouth of the Misouri river.

Q. How wide is the river at that point or place?

A. At the place where that region, or where that place begins, the Mississippi river is something more than a quarter of a mile wide.

Q. Now at this point that you speak of, as you go towards St. Louis, doesn't the left bank bear to the east and south?

3335 A. No sir, not to the east and south.

Q. What direction does it?

A. To the southwest approximately.

Q. How far before it turns towards the east and south?

A. A considerable distance below the city of St. Louis.

Q. You have no actual knowledge in regard to the currents at the different stages of the water, nor any actual knowledge of the mixing of these waters from any personal observation to any extent, and you are simply stating, or rather you are arriving at your conclusions from the curves alone, are you not?

A. I think I stated that my answer was based upon my general knowledge of the currents in rivers which had curves, and my knowledge of these curves as obtained from this Government chart.

Q. But you have no actual knowledge from any observations covering any considerable length of time as to currents, volume of water, and the mixing of the waters of the Missouri and Mississippi, other than your general knowledge of rivers and what this government chart shows with reference to the curves?

A. Not from any personal observations of the currents in the rivers, covering any considerable length of time.

Q. How far is it from Lockport by the Illinois River, to Peoria?

3336 **A. I don't recollect. I should have to consult some memoranda.**

Q. (Question repeated)?

A. About 130 miles.

Q. How far from Peoria to Grafton?

A. 161 miles.

Q. How far from Grafton to the mouth of the Missouri, if you know?

A. I think it is about 23 miles.

Q. And how far from the mouth of the Missouri to the intake?

A. About six miles.

Q. How far from Peoria to Beardstown?

A. About 74 miles.

Q. In the statements of the population made by you in your examination in chief, did you state the population of the watershed of the Illinois river?

A. Not the total population, no sir.

Q. What did you state in regard to the watershed of the Illinois river in regard to population?

A. I will look it up in the testimony.

Q. I will ask another question while that is being looked up in the testimony. The population when discussed and considered by scientists, you say is limited to the population 3337 of cities and villages of 4,000 and upwards?

A. No sir, I wouldn't say it was limited to that.

Q. Didn't you say that was the figure that scientists adopted?

A. They sometimes adopt it, yes sir.

Q. Didn't you make the statement that scientists used that arbitrary figure as the one upon which they based their research, and upon which they would arrive at any given conclusion, where population becomes an element to be considered?

A. That is one upon which they reach a conclusion, but it is not the only one. I don't think I conveyed that impression.

Q. Isn't it true that among all authors upon sanitary questions, that the population of the watershed instead of being based upon populations of 4,000 and above is based on what is known as the urban population; that is contiguous to the stream or the watershed and the rural population of the watershed?

A. It is not true that all authors use the amount of urban population and the amount of rural population instead of the population of cities which have more than 4,000 inhabitants.

Q. Don't you think that where the pollution of a stream is involved, that the rural population is an element that should be considered on the question of the discharge of sewage into that stream?

3338 A. I think that should be considered, yes sir.

Q. Do you know what the rural population of the Illinois watershed is?

A. Not from my recollection.

ADJOURNED until 2:00 P. M. same day, Thursday, May 14th, 1903.

3339 Southern Hotel, St. Louis, Missouri, 2:00 P. M., Thursday, May 14, 1903. Parties met pursuant to adjournment. Present the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE,

resumed the stand for further cross-examination by General Hamlin, and testified as follows:

Q. Do you know what the rural population of the Illinois watershed is?

A. I find from the report of Jacob A. Harman, included in a report of the Illinois State Board of Health, on sanitary investigations of the Illinois river and its tributaries, 1901, on page 119, that the total rural population of the Illinois River drainage basin in the year 1900 was 893,723.

Q. That is outside of Chicago?

A. Yes sir, that does not include Chicago, but only the natural drainage area of the Illinois river.

Q. And only the rural population?

A. And what he has called the rural population.

Q. Do you know what the urban population is, outside 3340 of Chicago, in the same drainage basin?

A. In the same report and on the same page to which I have referred, I find it stated that the urban population for the same region for 1900 was 617,664.

Q. Do you know how many creeks, rivers and tributaries there are to the Illinois river, having their watershed drain into the Illinois river?

A. I don't remember exactly, but I can tell by consulting a map of the stream.

Q. I will ask you if it is not a fact that the creeks, rivers and tributaries of the Illinois river, having their watershed drain into the Illinois river, is not about 25,000 miles?

A. Do I understand you to mean that the watersheds of the various rivers, creeks and streams have a total watershed of about 25,000 miles?

Q. No, has 25,000 miles of creeks, rivers and tributaries, draining portions of Indiana, Wisconsin and a large part of Illinois, into the Illinois River, which empties into the Mississippi near Grafton?

A. Unless we include the Chicago drainage canal as a tributary—

Q. No, I am not including that. Exclusive of the Chicago River, the Illinois and Michigan Canal and the Chicago Drainage Canal.

3341 A. Kindly repeat the question again.

Q. I will ask you if exclusive of the Chicago River and the Illinois and Michigan Canal and the Sanitary District Canal, if there are not about fifty creeks, rivers and tributaries to the Illinois River having their watershed drain into the Illinois River, making about 25,000 miles of creek, river and tributary draining portions of Indiana, Wisconsin and a large part of Illinois, into the Illinois River, which empties into the Mississippi River near Grafton?

A. I think that statement is approximately correct, but I find on page 120 of Mr. Harman's report, to which I have alluded, that the area of the watershed of the Desplaines river, the Kankakee river, the Fox river, the Vermillion river, the Mackinaw river, the Spoon river, the Sangamon river, Crooked Creek, McKee's Creek, Macoupin Creek, and a number of small tributaries not mentioned by name, that the sum of these drainage areas equals 27,914 square miles, and I have a memorandum made from the eleventh United States census which states that the drainage area of the Illinois river was 29,013 square miles, and another memorandum taken from the report of the chief of the Weather Bureau, from 1896 to 1897, which states that the drainage area of the Illinois river was 29,150 square miles.

Q. In my question I was not referring to the area or 3342 number of square miles but to the number of miles of the Illinois river and its tributaries, exclusive of the Illinois and Michigan Canal, the Chicago River and the Drainage Canal?

A. Do you mean the number of lineal miles up and down the streams?

Q. Yes sir?

MR. JEFFRIES: The first question, as I understood it, did not include the Illinois river, but only its tributaries and their tributaries?

GENERAL HAMLIN: No, I mean the Illinois River—to 25,000 miles of Illinois River and its tributaries, exclusive of the Chicago River, the Illinois and Michigan Canal and the Drainage Canal—if there is not that many miles of creek and river?

A. I have no personal knowledge of that fact.

Q. You don't know then?

A. I don't know that there are 25,000 lineal miles of river.

Q. In the statement from which you have read in your answer to the former question, did you include the Kankakee River?

A. In speaking of the drainage area in square miles?

Q. Yes, you had it there on a slip of typewritten paper in which you gave the list of tributaries.

A. I understand that that is included.

Q. Did you give the Kankakee?

A. No sir, there was no reference to the Kankakee river
3343 on this typewritten piece that I have here.

Q. Did you intend to include the Kankakee in your statement that you made in the answer to the former question?

A. When I read from this typewritten paper that the drainage area as taken from the Eleventh census of the United States was 29,013 square miles, I understand that that does include the area of the Kankakee river.

Q. And its tributaries?

A. Yes sir.

Q. You don't know that that is true from your own knowledge, or from any examination that you have made?

A. From the statement that that was the watershed of the Illinois River and inasmuch as the Kankakee river drains into the Illinois River, I assume that that is included.

Q. Do you know where the source of the Kankakee River is—in what state?

A. I guess I will have to refer to that map. (Witness refers to map).

Q. (Question repeated)?

A. In the state of Indiana.

Q. Do you know how many tributaries it has?

A. I don't know exactly, but upon the map which accompanies, or which forms a part of the report of the State Board of Health—of the Illinois State Board of Health on the sanitary investigation of the Illinois Rivers and tributaries for
3344 1901, I find depicted about twenty of those tributaries.

Q. Of the Kankakee?

A. Of the Kankakee river.

Q. How many tributaries are there to the Illinois River, exclusive of the Illinois and Michigan Canal, the Drainage Canal and Chicago River, in number, if you know?

A. I can't state exactly the number of tributaries which flow into the Illinois River, but on the map of the Illinois river and of the Illinois and Michigan Canal—

Q. I have excluded that.

A. I know, but I am simply naming the title of the map.

Q. Well, that wouldn't answer my question.

A. But on a map of the Illinois River and of the Illinois and Michigan Canal, reduced from maps showing surveys of Lieutenant Colonel J. H. Wilson, in 1867, under the direction of Captain C. J. Lydecker, of the corps of engineers, I have counted more than 50 tributaries which flow into the Illinois River.

Q. Is there anything that shows the number of miles now of those tributaries, including the Illinois, exclusive of the Chicago River, the Drainage Canal and the Illinois and Michigan Canal?

A. There is nothing upon this map which shows the lengths of those tributaries.

Q. Then as to whether there is 25,000 miles in length of
3345 them, you don't know, from either anything that you know personally or from any maps or reports that you have access to; is that what you mean to say now?

A. I don't know it from any personal knowledge, or from any maps or reports which I have seen.

Q. And you don't know the rural or urban population comprised within the territory of the Illinöis River and the tributaries about which I have just asked you, first, of your own personal knowledge, or from any investigation that you have personally made?

A. I don't know the rural population dwelling upon the Illinois river, and its tributaries, exclusive of the Chicago Drainage Canal, from personal knowledge, as I have never counted the inhabitants. I know them simply from the report to which I have referred, namely, that of Mr. Jacob A. Harman, in which he states that the rural population upon that watershed is 893,723.

Q. That report does not undertake to give the urban and rural population of all the tributaries of the Illinois River, does it, outside of the Chicago River, Illinois and Michigan Canal and Drainage Canal?

A. When you say this report, do you mean this particular table in this report?

Q. I mean that report that you have referred to?

3346 A. You mean the report of Mr. Harman of this—

Q. Yes sir.

A. I think it does not.

Q. Well, it is impossible for you to say, is it not, how much sewage is discharged into the Illinois River and its tributaries, outside of the Illinois and Michigan Canal, the Drainage Canal and the Chicago River?

A. It is impossible for me to say.

Q. It is impossible for you to say, is it not, how much water reaches the Illinois River from its tributaries, exclusive of the Drainage Canal, the Illinois and Michigan Canal, and the Chicago River?

A. It is impossible for me to say exactly, but it would be possible to obtain an approximate idea by comparing the relative drainage areas of the tributaries of the Illinois River, with the drainage area of the Illinois river above some point in that river, as for example, at Peoria, Illinois, where there are data on record which give the discharge of the stream of the Illinois river at that point.

Q. What do you say about Grafton?

A. Well, what about Grafton?

Q. As to the same plan to be pursued at Grafton, whether you could tell or not?

A. As to whether I am able to state, do you ask me
3347 whether I am able to state—whether I can state the discharge of the Illinois River at Grafton—the amount of water discharged?

Q. The amount of water carried into the Illinois River from its tributaries?

A. I am unable to state that exactly, but I can make an approximate calculation of the amount of water there discharged by comparing the drainage area of the Illinois River above Grafton, with the drainage area of the Illinois River above some point such as Peoria, where data in regard to the discharge of water are known, and where the drainage area of the Illinois river above the point is known, making due allowance for any flow of water that might enter from the Chicago Drainage Canal.

Q. Well, you haven't made these calculations at all, have you Mr. Whipple?

A. (Witness refers to charts).

Q. Just answer the question whether you have or not, first.

A. I have personally made one or two such calculations.

Q. You have not made any such calculations that you would say would be reliable, covering a period of six months or a year, have you?

A. I have not made such calculation personally—

Q. Well, that answers the question.

3348 THE WITNESS: I haven't finished my answer.

Q. Well, I don't care to go into it unless you want to go into it. You can put that in on re-direct. My idea is to limit the inquiry.

GENERAL CROW: I suggest that you have no right to shut the witness off in his answer.

GENERAL HAMLIN: I will insert the word "personally" there in that question.

Q. (Question read as follows:) You have not personally made any such calculation that you would say would be reliable, covering a period of six months or a year, have you?

A. No sir, but I have personally directed the preparation of certain memoranda, from which such calculations can be made.

Q. From what period?

A. From a period from August, 1899, to October, 1900, inclusive.

Q. You have no means of telling with any degree of certainty, the amount of sewage discharged into the Illinois River exclusive of the Chicago River, the Illinois and Michigan Canal, and the drainage district, have you?

A. No sir.

Q. When you speak then of the typhoid bacillus reaching the intake at the city of St. Louis, if such a thing should 3349 occur, you have no means of knowing or saying where such typhoid bacillus would come from, have you?

A. I couldn't say definitely.

Q. You couldn't say with any certainty, could you?

A. I couldn't say certainly, without comparing the population which drains into the Chicago Drainage Canal, and thence into the—I will say the sewered population which drains into the Chicago Drainage Canal and thence into the Illinois River, with the rest of the sewered population on the watershed of the Illinois River and its tributaries, and the Mississippi river above the Illinois River and the Missouri river.

Q. Well, Mr. Whipple, you are an expert are you, on typhoid fever germs?

A. Yes sir.

Q. Now as such an expert, if typhoid fever germs were discharged into the Mississippi river at Alton, or the Missouri river at St. Charles, on the Missouri River; wouldn't they more likely reach the intake than if discharged into the stream say 300 miles away—the streams that compose the Mississippi River before it reaches the Intake?

A. That would depend upon a series of conditions, among which would be included the number and character of the typhoid bacilli discharged; the distance of the point of discharge from the intake of the St. Louis Waterworks, along the water courses; the manner in which the several streams mentioned become mixed before the water reached the intake of the St. Louis waterworks, and the character of the water into which the typhoid fever bacilli were discharged.

Q. Assuming the conditions of the various streams of water about which you have testified, would a typhoid bacillus discharged in the water at Alton or St. Charles, be more likely to reach the intake at St. Louis, than it would if discharged into any one of these streams 350 miles away?

GENERAL CROW: Now we object to the question for this reason, that it does not state the conditions under which the bacilli are supposed to enter the water at either place, neither as to time nor manner, nor does it state any conditions with reference to the location of the St. Louis waterworks so far as distance is concerned, from the same.

MR. JEFFRIES: Nor does the assumption state the condition of the respective waters about which the assumption is made.

THE WITNESS: Now read my answer to the next to the last question, if it is proper.

GENERAL HAMLIN: I don't see how you could do that. You are an expert; the question is plain.

GENERAL CROW: Well, he has a right to do that if he wants to. You have no objection to him looking at the answer, have you?

3351 GENERAL HAMLIN: No, that is no way for a man who is competent, to do. If it was in a Court, it would not be permitted.

GENERAL CROW: Yes, I think it would. I don't know of any rule of law what would exclude it.

GENERAL HAMLIN: I have no objection, if he wants to look at it.

THE WITNESS: Well, never mind. Leave that out. You might read the last question again.

Q. (Last question read)?

A. I have not testified to enough of the conditions mentioned to enable me to answer the question.

Q. GENERAL HAMLIN: Assuming the conditions of the various streams composing the Mississippi river at the intake at St. Louis, as you understand them, would a typhoid bacillus discharged into the Missouri River at St. Charles, Missouri, or at Alton on the Mississippi River, more likely reach the intake at St. Louis than a typhoid bacillus discharged in the water of any of these streams 350 miles away from the intake?

A. Now I would like to have that question read again, to refresh my memory.

Q. (Question read).

A. In so far as the question of distance alone, is concerned a typhoid fever bacillus would reach the intake of the St. Louis Waterworks from St. Charles, Missouri, or from Alton, Illinois more easily than a typhoid bacillus of equal vitality in-
3352 troduced at a distance of 350 miles from the intake of
the St. Louis Waterworks; but whether or not a typhoid bacillus discharged at St. Charles or at Alton would actually reach the intake of the St. Louis waterworks more easily than a typhoid bacillus of similar vitality, discharged at a distance of 350 miles from the intake, would depend among other things upon the degree of mixing of the waters into which the bacilli were discharged, before they reached the intake of the St. Louis waterworks, and to some extent perhaps, upon the character of

the water into which the bacillus which was introduced at a distance of 350 miles from the intake of the St. Louis waterworks, was introduced.

MR. TODD: What was the last part of that answer?

(Answer read).

THE WITNESS: Just wait a minute; perhaps I have not finished my answer.

GENERAL HAMLIN: Go ahead, you can have all the time you want, as far as that is concerned.

THE WITNESS: Just read the first part of that answer again.

(Answer read.)

A. (continuing) And it would depend still further upon the velocities of the streams into which the bacilli were discharged at the three points mentioned.

Can I change the first part of that answer some?

3353 GENERAL CROW: Yes, change it to suit yourself?

GENERAL HAMLIN: Let the answer stand as originally given, though, and give the new asnwer.

GENERAL CROW: No, he has a right to answer this question as he pleases.

GENERAL HAMLIN: Oh, he has to give another answer.

GENERAL CROW: But he has to sign his testimony. You don't undertake to say that if a man wants to correct his answer, that he can't do it.

GENERAL HAMLIN: No, the point is this; that the answer stands, but if he makes a correction, both the answer and the correction should be shown.

GENERAL CROW: No, I don't understand that. If he doesn't want a thing to go in as an answer, he don't have to put it in. In other words, he don't have to put in anything that he does not want to put in.

GENERAL HAMLIN: We don't put anything into his mouth.

GENERAL CROW: But when he wants to change the answer; he can do so.

GENERAL HAMLIN: When you put the testimony in before the Court, you are right, of course, but where you have no power of objection and no power of passing upon a question, then the record must show what actually takes place. That is the rule.

GENERAL CROW: (To witness) I don't suppose you care whether it goes in or goes out?

3354 THE WITNESS: As long as I get my answer in, I don't care. I was simply going to say in the first part of the question that which I did reserve to the last part.

GENERAL CROW: Well, just start in and answer it again, if you want to.

THE WITNESS: Do you mean that I should start and answer the question all over again?

GENERAL CROW. If you wish to, perhaps that would be better, to get it connected.

THE WITNESS: Read the question again.

Q. (Question read).

THE WITNESS: Will you read my original answer?

(Answer read).

THE WITNESS: I guess I will let that stand.

Q. GENERAL HAMLIN: If it depended on velocity, the one nearest the intake would reach the intake first, wouldn't it?

A. Provided the velocities of the streams were such that the one which was nearest the intake got the shortest time of transit.

Q. Well, Alton is nearer the intake than a point 350 miles away, isn't it?

A. In so far as that flow is concerned, as I understand it.

Q. Well, that disposes of velocity. Now so far as the vitality is concerned, do you want to be understood that a typhoid bacillus with equal vitality at Alton, and starting on his journey to the intake, with one of equal vitality 350 miles away, that one would be as liable to reach the intake as the other, and still maintain their vitality? 3355

A. Now will you read that question again?

Q. (Question read).

A. I do not understand that question.

Q. Well, it is plain.

A. I don't think it is. Will you kindly read it again?

Q. (Question read).

A. If, by vitality, you mean the ability to resist external conditions, that would depend upon the relative character of the water into which the bacillus was introduced at Alton, and the water into which the bacillus was introduced at a distance of 350 miles, and the time required for the bacillus to travel from Alton to the intake of the water works, as compared with the time required for the bacillus to travel from a point 350 miles away to the intake of the waterworks.

Q. That is your answer?

A. That is my answer.

Q. What is the area of the watershed of the Mississippi river above Grafton, the Missouri river and the Illinois river exclusive of the Illinois and Michigan Canal, the drainage canal and the Chicago river?

3356 A. From the memorandum which I have I read that according to the Eleventh census of the United States, the drainage area of the Missouri river was about 527,000 square miles, while the drainage area of the Missouri river according to the report of the Chief of the Weather Bureau for 1896 and 1897, was about 527,150 square miles; that the drainage area of the Mississippi river above Grafton, according to the Eleventh United States census was about 143,512 square miles, while according to the report of the Chief of the Weather Bureau for 1896 and 1897, it was about 126,750 square miles, while the drainage area of the Illinois river, exclusive of the Chicago drainage Canal and the Illinois and Michigan Canal—that's the way you worded it isn't it?

Q. Yes, and the Chicago River?

A. Was, according to the Eleventh United States census about 29,013 square miles, while according to the report of the chief of the Weather Bureau for 1896 and 1897, it was about 29,150 square miles.

Q. Making a total of how much, exclusive of the Chicago River, the Illinois and Michigan Canal and the Drainage Canal?

A. Making a total for the three watersheds of the three rivers mentioned, and excluding the canals named, of 699,525 square miles, according to the figures of the Eleventh United

States Census, and 693,050, according to the Chief of the Weathe Bureau for 1896 and 1897.

3357 Q. What is the urban population of this drainage area, exclusive of the Illinois and Michigan Canal, the drainage canal and the Chicago River?

A. When you state "this drainage area," do you mean th total population of the three?

Q. Yes, the urban population?

A. You mean the sum of the three?

Q. Yes?

A. If, by urban population we include the population onl of those towns and villages and cities which contain more tha 4,000 inhabitants, I find on page 27 of the report on the wate supply of the City of St. Louis, by the Commission of Hydrauli Engineers, dated 1902, that the aggregate urban population o the three watersheds mentioned in the last question was, according to the United States Census of 1900, 2,694,738.

Q. Now, if to that you add the rural population in thi basin that is contiguous to those watersheds or the streams tha connect with those various rivers, exclusive of the Illinois an Michigan Canal, the drainage canal and the Chicago river, wha do you find it to be?

A. Read me that question.

Q. (Question repeated).

A. I will have to have the question repeated again.

Q. (Question repeated)?

3358 A. I am unable to state because I don't know what th rural population referred to is.

Q. I will get you to state if it is not a fact that in this are of these three rivers that you have mentioned, that is within thes drainage basins, exclusive of the Chicago River, the Illinois an Michigan Canal and the Drainage District, if the population, according to the United States census, was over 12,000,000?

A. Read me that question.

Q. (Question read).

A. I don't know, as I haven't made any estimate of such population.

Q. Have you tried to ascertain as to this population o these drainage basins about which you have just been asked, exclusive of the Chicago river, the drainage canal and the Illinois and Michigan Canal?

A. Repeat the question.

Q. (Question repeated)?

A. I have not tried to estimate the total population. Repeat the question.

Q. (Question repeated)?

A. I have not tried to ascertain it.

Q. You do know that the Platte is a tributary of the Missouri River, don't you?

3359 A. Yes.

Q. And that Denver is located there?

A. Yes sir.

Q. Do you know where the towns of Bismarck, Pierre, Sioux City, St. Joe, Kansas City and Jefferson City are? They are all on the Missouri River, aren't they?

A. I guess you will have to name that list again.

Q. Bismarck, Pierre, Sioux City, St. Joe, Omaha, Kansas City and Jefferson City?

A. Do you mean Kansas City, Kansas, or Kansas City, Missouri?

Q. Both?

A. Is that the list?

Q. Yes.

A. (No answer).

Q. Well, you know that Minneapolis, St. Paul, LaCrosse, Galena, Rock Island—

A. Shall I answer the other question?

Q. I don't care to take up time with it. Those are prominent towns on the Missouri river.

GENERAL CROW: We will admit they are there of course.

GENERAL HAMLIN: Minneapolis, St. Paul, LaCrosse, Galena, Rock Island, Davenport, Burlington, Quincy and Keokuk, are on the Mississippi river above Grafton, are they not?

A. Yes sir.

Q. While on the Missouri River and its tributaries, there

3360 is an innumerable number of towns ranging from 500 to 4,000 people are there not?

A. I have no doubt there are towns ranging from 400 to 5,000 people, but I wouldn't say they are innumerable.

Q. You don't know?

A. (No answer).

Q. Now assuming that the population of these three drainage basins of the Illinois River, of the Missouri River and of the Mississippi river above Grafton, exclusive of the Illinois and Michigan Canal, the drainage canal and the Chicago river is, according to the United States census of 1900, over 12,000,000, what would be the proportion that the population of the sanitary district of Chicago and the towns tributary to the Illinois and Michigan Canal above Lockport and the Drainage Canal, bear to such population?

GENERAL CROW: Now do you mean included in the drainage area of the Chicago Canal?

GENERAL HAMLIN: No sir.

THE WITNESS: Repeat the question.

GENERAL CROW: You do not mean, included?

GENERAL HAMLIN: No, I am talking about the population.

Q. (Question repeated)?

GENERAL CROW: You said population in the drainage area of the drainage canal.

3361 THE WITNESS: You may want to include that, but perhaps we had better have the question read again.

GENERAL HAMLIN: I will change that, to the population of the Sanitary District of Chicago.

Q. (Question read as amended).

A. It would be about 13.6 per cent if we assume that the total population of the Sanitary District is 1,639,456, according to the United States census, which figure I am reading from some memorandum prepared by Mr. Benezette Williams.

Q. Assuming that based upon the population given in the former question, that the sewage discharge from the population into the Missouri river, from the basin of the Missouri river, and of the population of the basin of the Mississippi river above

Grafton, and of the population in the basin of the Ilinois river, exclusive of the Illinois and Michigan Canal and the Drainage Canal above the Bear Trap Dam, and the Sanitary District, what would be the percent of sewage discharged by the sanitary district, the Illinois and Michigan Canal above the Bear Trap Dam and the Drainage Canal, as compared with the sewage discharged into the Missouri river from the population of the Missouri river basin, and the population of the Mississippi river from the Mississippi river basin above Grafton, and the population of the basin of the Illinois river, exclusive of the Illinois and Michigan Canal, the Drainage Canal and the Chicago River?

3362 A. Read that question.

GENERAL CROW: Now we want to interpose an objection to that question for the reason that it is unfair in this; that he institutes a comparison between the sewered urban population and rural unsewered population, without making any allowances for the difference in the sewage matter that might pass into the Missouri, the upper Mississippi and the Illinois, or to the effect that might be produced on the waters of the said streams.

A. Read that question.

Q. (Question repeated).

A. Now will I answer the question?

GENERAL HAMLIN: Yes.

A. If we assume there are 12,000,000 inhabitants living upon the watershed of the Missouri river and the Mississippi river above Grafton, and the Illinois above Grafton, exclusive of the population living within the Chicago Sanitary District, and if we assume that there are living within the Chicago sanitary district 1,639,456 inhabitants, and if we assume that the amount of sewage from each individual is the same as the amount of sewage from every other individual upon the three watersheds mentioned, and within the sanitary water district, and if we assume further that all the sewage of all these individuals mentioned as living upon the three watersheds, and within the
3363 Sanitary District, empties into the streams mentioned, the
amount of sewage contributed by the inhabitants of the sanitary water district of Chicago would be about 13.6 per cent of the amount of sewage contributed by the 12,000,000 popula-

tion dwelling upon the three watersheds mentioned, exclusive of the Chicago Sanitary District.

Q. Do you know how much sewage actually enters the Illinois river outside of the Sanitary District or of the Missouri river, or of the Mississippi river above Grafton?

A. Will you read that again?

(Question repeated).

A. I don't know exactly, but I know there are upon the watersheds of the Missouri River about 63 cities, towns and villages which had a population of 4,000 and over according to the United States census for 1900, and which had an aggregate population of about 1,090,832 according to that census, and there are upon the watershed of the Mississippi river, above the mouth of the Missouri, about 74 cities, towns and villages, which had populations of 4,000 and over according to the United States census of 1900, and which had an aggregate population of 1,219,645 and that according to the same census there are upon the watershed of the Illinois river, exclusive of the sanitary District, about 30 cities, towns and villages having a population of 4,000 and over and which have an aggregate population of about
3364 384,261, and I know that speaking generally for the United States, cities, towns and villages which have populations of 4,000 and over are liable, ordinarily to have sewerage systems and that cities, towns and villages which have less than 4,000 population are ordinarily not so liable to have sewerage systems and public water supplies, and that therefore, the population included in cities of such size, located upon the watersheds of the Missouri river and the Mississippi river and the Illinois river as above mentioned, afford a reasonable basis for comparing the relative amounts of sewage discharged into the Missouri river, the Mississippi river and the Illinois river as above mentioned?

Q. How far, according to the authenticated cases of the contamination of water that has produced typhoid fever, has been the distance from the point or place where typhoid fever was contracted by water contamination?

A. I will have to refresh my memory on that.

Q. Can't you give from recollection substantially?

A. I can give a general idea from my recollection, without going into details. Will you read the question again?

Q. (Question repeated).

A. To the best of my recollection, and in the absence of my notes, it is my opinion that this distance has been as great
at times as 50 or 60 miles.

3365 Q. Do you know of any well authenticated case in the
books where it has been beyond sixty miles?

A. No sir, unless some of the cases which I have in mind should be somewhat more.

Q. Isn't it true that the majority of cases that have been reported in this country and in Europe, are less than thirty miles?

A. Yes, I should say that the majority of the well recognized epidemics caused by water borne typhoid fever bacillus were due to infection less than thirty miles distant.

Q. Did you give the amount of typhoid fever cases in St. Louis in 1901 and 1902?

A. No sir, but I think that the numbers of such cases were mentioned in an assumption included in a question which was asked me.

Q. Suppose in 1902 that the number of reported cases of typhoid fever in St. Louis was 1112, and the number of deaths was 222, and that the same year, at St. Charles, Missouri, a distance of 35 miles—St. Charles then having a population of 7982—and the sewage of St. Charles, including that of two or more hospitals, and the public schools, as well as the population of the city, and that for the year 1902, typhoid fever was epidemic in St. Charles, and assuming further that the sewage thus dis-
charged from St. Charles, was carried down the Missouri
3366 river to the Mississippi river, and from there to the intake
of the St. Louis waterworks, traveling that distance in that
way. To what then, would you attribute the increase of typhoid fever cases and deaths in St. Louis, for the year 1902?

A. I should say that the facts assumed, without considering other cases of typhoid fever that might exist upon the watersheds of the Missouri river and the Mississippi river above Grafton, and the Illinois river and the Chicago Sanitary District and without considering the time when typhoid fever was assumed to be epidemic in St. Charles, and the time when the assumed increase of typhoid fever in the City of St. Louis, and without considering the relative flows of the streams mentioned, and the amount of sewage discharged into the different streams, and the amount of sewage discharged by the Chicago Sanitary District and the manner in which the waters of the three streams mentioned were mixed, before reaching the intake of the St. Louis waterworks, and without considering possible local causes for the assumed increase in the typhoid in the City of St. Louis, the assumption made is insufficient for me to answer the question.

G. C. WHIPPLE.

ADJOURNED until 10:00 A. M. following day, Friday, May 15, 1903.

3367 Southern Hotel, St. Louis, Missouri. 10:00 A. M., Friday, May 15th, 1903. Parties met pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE,

Resumed the stand for further cross-examination by Attorney-General Hamlin, and testified as follows:

Q. Mr. Whipple, assuming that St. Charles, Missouri is located on the left bank of the Missouri River twenty miles above its mouth, where it empties into the Mississippi river, and that the mouth of the Missouri river is situated six miles above the intake and assuming further that prior to the first day of February, 1903, that the City of St. Charles was supplied with Missouri River water from a pumping plant having two settling basins, and an intake into the river located on the river front, and assuming for the year 1902, that the city of St. Charles had four public sewers, ranging from three or four blocks in length to eight blocks in length, draining the business district and portions of the more populous residence territory, besides, there being many private sewers from hotels and business houses leading into the river, and that on Main Street, which is parallel with and one block from the river there are five hotels and one or two livery stables, all of these having sewers draining into the river, and that there is a public hospital 3368

located four blocks from the river which has a sewer leading into the river, said hospital accommodating in the year 1902, twenty patients; and that on Madison Street in the city of St. Charles, one block down stream from the former sewer, is a sewer ten inches in diameter, which receives the sewage from one of the public schools of the city, where 250 pupils attend. In addition to the sewage from this school this sewer also receives other sewage from buildings located on or above Madison Street for a distance of four blocks from the river; that on Clark Street in said city is a sewer leading up the same from the river a distance of seven blocks to the Benton School, which school had in attendance in the year 1902, sixty pupils; there also being a very considerable number of residences, also connected with this sewer; also that in the year 1902, the sewage from the Convent of the Sacred Heart, having about 100 inmates, and also the sewage from the private schools maintained by the Catholics for day pupils, which have an attendance of about 250. In addition to this there are a number of public buildings connected with this sewer from the private schools maintained by the Catholics and that altogether about 70 per cent of the sewage pro-
3369 duced in the City of St. Charles is drained by means of public sewers, directly into the Missouri River, and that the streets of St. Charles, which are at right angles to the river, having steep slopes, and the surface drainage runs repeatedly into the river and washes the streets thoroughly at each down-pour of rain, and assuming further that the city of St. Charles has four cemeteries located in the southwest portion of the city; that these cemeteries are on broken ground about 100 feet above the level of the Missouri river; that the natural drainage of these cemeteries is through a number of ravines which ultimately gather into one large ravine leading into the Missouri River and finding an outlet about 300 yards below the present intake of the waterworks at St. Charles; and assuming further that St. Charles had a population of 7,982 in the year 1902, and assuming further that the number of deaths from typhoid fever in the city of St. Charles was 18 for the year 1902, as follows:

4 in the month of January,
1 in February,

3 in March,
3 in April,
1 in May,
1 in July,
1 in August,
1 in September,
3370 1 in November,
2 in December;

Assuming further that the sewage mentioned and the drainage from the four cemeteries mentioned passing into the Missouri River, thence to its mouth; thence from its mouth down the Mississippi River to the intake; and assuming further that the sewage discharged from the sanitary district of Chicago into the Drainage Canal, passing down the Drainage Canal over the Bear Trap Dam, thence into the Des Plaines and Illinois Rivers, and assuming further that at the Narrows on the Illinois River above Peoria, that a chemical analysis of the water and a bacteriological examination of the water at this point in the year 1902, showed substantially no pathogenic germs; then, eliminating all other conditions or causes that might have produced typhoid fever in the city of St. Louis in the year 1902, and comparing the situation at St. Charles, Missouri as stated in this question, and the condition of the water at the Narrows above Peoria, then in your opinion, considering these conditions alone and apart from any other consideration, if you were called upon to decide as an expert, as to these two causes alone, which, in your judgment, would be the cause of the existence or increase of the typhoid fever in the city of St. Louis in the year 1902?

A. If we consider only the conditions which are assumed 3371 to exist at St. Charles, and compare these with the assumed fact that at the Narrows on the Illinois River above Peoria, the chemical analysis of the water and the bacteriological examination of the water shows substantially no pathogenic germs, and if we eliminate all other conditions or causes that might have produced typhoid fever in the city of St. Louis in the year 1902, I should be unable to decide as to the assumed increase in the amount of typhoid fever in St. Louis for the year 1902, for this reason, among others: that simply because the chemical analysis of the water and the bacteriological examination of the water shows substantially no pathogenic germs, it does not follow that that water so examined, did not contain them.

JUDGE JOHNS: We reserve the right on the part of the State of Illinois, to further cross-examination.

MR. WOERNER: All right.

CROSS-EXAMINATION, By Mr. Todd.

Q. How is the presence of sewage in water determined?

A. The best way to determine it is to actually find out whether or not sewage enters the water.

Q. Well in the absence of that information can water be taken from a river and by any process known to science, can it be determined whether that water is sewage polluted or not?

A. Just read that question again.

3372 Q. (Question read.)

A. In answer to that I will say that some water can be and some water cannot be.

Q. What water can be and what water cannot be?

A. If water is much polluted with sewage that fact can be ascertained by scientific methods; if it is but very slightly polluted with sewage, it cannot always be determined by scientific methods.

Q. What degree of pollution would you denominate "much polluted" as contained in your former answer?

A. I am unable to state that in general terms.

Q. Have you any idea on the subject?

A. I have not a definite idea.

Q. Do you have any idea of the ratio of pollution of pure water to sewage that would be included in the answer "much polluted?"

A. I have not a definite idea because it would depend not alone on the amount of pollution, but also on the character of the water which was polluted.

Q. What do you mean by the character of the water that was polluted?

A. I mean the character of the water as shown by those qualities which might be used in determining the possible pollution of the water.

3373 Q. What are those qualities which enable you to determine the possible pollution of the water, in water?

A. There are no qualities in the water which, taken alone, would enable me to determine the possible pollution of the water, but among the qualities which I should naturally consider in forming an opinion as to the possible pollution of the water would be the amount of organic matter as shown by the albuminoid ammonia—

Q. As shown by what?

A. The albuminoid ammonia, and the character of the organic matter with reference to its decomposition as shown by the free ammonia, the nitrites, the nitrates, the amount of chlorine in the water and the hardness of the water; the total solids, the suspended solids and the color of the water, meaning by that the organic matter in solution which exhibits itself as a vegetable stain; the number of bacteria in the water and the presence of certain particular species of bacteria such for example as the bacillus coli communis.

Q. Is that all, doctor?

A. No, not quite. Let's see. I am still thinking.

Also the possible presence of certain microscopic organisms commonly associated with sewage pollution—just read that answer please.

(Answer read.)

3374 A. (Continuing.) As a matter of punctuation, I do not wish it to be understood that I include the chlorine as one of the qualities which would indicate the decomposition.

Q. Is that completed?

A. Yes sir.

Q. Are these the qualities to which you referred in the former answer, in water, what would enable you to determine whether water is much polluted or not by sewage?

A. Yes sir.

Q. In the absence of knowledge that sewage entered the waters, can the fact that the water is sewage polluted be ascerained from the different elements that you have enumerated ere in your previous answer?

A. Just read that question again.

Q. (Question read.)

A. I believe that at times it can be, and that at other times t cannot be?

Q. What are the times that it can be and what are the times hat it cannot be?

A. I believe that it can be when the amount of sewage pollu-ion is considerable, and that it cannot be when the amount of ewage pollution is very slight.

Q. The word "considerable" as you use it, is a relative term, is it not?

375 A. Yes sir.

Q. Now what proportion of sewage, to the volume of vater into which the sewage enters, is necessary to arrive at the lignity of "considerable" as you use it?

A. I am unable to state, as that depends upon the character f the sewage and the character of the water into which this ewage is discharged.

Q. Now take the character of the water into which the ewage is discharged; what kind of water do you have refer-nce to?

A. I don't understand what you mean by "what kind of vater."

Q. What do you mean by "that it depends upon the char-cter of the water into which the sewage is discharged"—what lo you mean by the word "character" as used in your answer?

A. I mean its character with respect to the qualities enu-nerated as being those which I should consider in endeavoring o determine whether the water was or was not polluted with ewage.

Q. What is the character with reference to the qualities nuemerated to which you refer in that previous answer?

A. I mean that if the qualities of one water more nearly esemble the qualities of a certain sewage than the same quali-ies of another water, it would be more difficult to ascertain vhether the former water were polluted with that sewage than in the case of the latter.

3376 Q. In other words, to see if I understand you, it would be a question of whether the water polluted the sewage or the sewage polluted the water under those conditions; is that right?

A. It would be—just read the question again.

Q. (Question read.)

A. It would be a case of comparing the water with the sewage.

Q. Under the state of facts that you have enumerated in your previous answer, wouldn't it also involve a comparison of the sewage with the water?

A. We should compare the water with the sewage and the sewage with the water.

Q. Then what would be the character of the water necessary to enable you to ascertain when sewage empties into that water, whether it is sewage polluted or not?

A. Just read that once more.

Q. (Question read.)

A. The character of the water will have to be different from that of the sewage, but just how different I am unable to state,—or I will say, to what extent it is different I am unable to state.

Q. In what manner is it possible to express that difference between the water and the sewage in a scientific way?

A. It is possible to express that difference by a determination of the qualities which I have enumerated.

3377 Q. It is necessary to determine the presence of organic matter in the form of albuminoid ammonia, or organic matter in the form of decomposition known as free ammonia, nitrites, nitrates, hardness of the water, total solids, solids in solution, the presence of bacillus coli communis, in the water, before the sewage enters into it, in order to ascertain whether that water would become sewage polluted or not?

A. Just read the first part of it again.

Q. (Question read.) By the presence of sewage, being added?

A. It is not always necessary to determine all of the qualities that you have enumerated.

Q. Assume that you determine the absence of all these qualities in water before the sewage enters into the water, what proportion, then, of the water, with the absence of these elements and sewage that would enable you to determine the presence of sewage in water of that character?

A. Now will you just read that again?

Q. (Question read.)

A. If you mean by that question the proportion of sewage in a water free from those qualities mentioned, as shown by the amounts of those qualities, after mixture of the sewage with the water, I could not tell the proportion unless I knew the character of the sewage and the changes which might have occurred between the time when the sewage was added to the
3378 water and the time when the analysis was made.

Q. What about the character of the sewage, would you want to know, in order to ascertain that fact?

A. I should want to know one or more of the qualities which have been enumerated.

Q. Before the sewage enters the water?

A. Yes sir.

Q. How would those facts be ascertained?

A. By making analyses.

Q. Then, in order to ascertain the presence of sewage in water of the character that we have been talking about, with these elements eliminated, is it necessary to make a chemical analysis of the sewage before it enters that water, in order to ascertain the proportion of the sewage to the water into which it enters, in order to ascertain its presence?

A. In order to ascertain the proportion of the particular sewage mentioned, it would be necessary to make some sort of an analysis.

Q. Then, in the absence of any analysis having been made of the sewage before it enters the water, is it possible to ascertain the presence of the sewage in the water into which it empties?

A. Just read that again, please.

Q. (Question read.)

3379 A. It might be possible to ascertain its presence, but not its exact proportion.

Q. At what proportion of sewage to water, is it impossible to detect the presence of sewage in water?

A. I am unable to state, as it depends upon the character of the sewage and the character of the water.

Q. Take the waters of Lake Michigan and the sewage of Chicago: what proportion of the water of Lake Michigan would be necessary to mix with the sewage of Chicago and the sanitary district in order to enable you to ascertain the presence of sewage in a mixture of that character?

A. Once more please.

Q. (Question read.)

A. I am unable to state.

Q. Do you know the character of the sewage of the Sanitary District before it mingles with the water of Lake Michigan?

A. I know certain characteristics of it from published analyses.

Q. Are those characteristics sufficient to meet the requirements of your previous answer, in regard to the condition of sewage before it enters the waters of the kind that we have been talking about?

A. Yes, so far as they alone are concerned.

3380 Q. Do you know the character of the water of Lake Michigan as free from the sewage of Chicago and the Sanitary District?

A. I know certain characteristics of the water of Lake Michigan as used in the water supply of the city of Chicago.

Q. That is impregnated with sewage, is it not? Do you know?

A. I know that it has been stated that at times such is the case.

Q. Well, do you know the character of the waters of Lake Michigan when freed from any sewage pollution from Chicago?

A. Only from analyses of such portions of Lake Michigan as are used for the water supply of the city of Chicago.

Q. And do you know whether that is free from sewage contamination or not?

A. I couldn't state definitely.

Q. Are you able to state from your knowledge of the sewge of Chicago before it commingles with the waters of Lake lichigan at what proportion of water to sewage you would be ble to ascertain the presence of sewage in that water?

A. No sir.

Q. Your experience as a scientist has not enabled you to nake that kind of a determination, has it?

A. It has not enabled me to determine that point exactly.

Q. Do you know of any scientist of established standing, r admitted standing that has been able to solve that proposiion?

A. I do not know of any such scientist who has really been able to solve it. ;381

Q. Then the line between much polluted water and lightly polluted water has never been scientifically defined as o the ratio of sewage to water, or dilution, has it?

A. It is my opinion that it has not been truly defined, and hat it cannot be truly defined.

Q. Now in the absence of any knowledge that sewage eners water, or the character of the water when the sewage entered t, a scientist is able to ascertain the presence of sewage in that vater with the absence of that knowledge isn't he?

A. If a scientist did not know that the sewage entered the vater, and if he didn't know the character of the water before he sewage entered it, the question of whether he could determine the probable presence of sewage in that water, would depend in part, upon the original character of the water and the haracter of the results shown by his analysis.

Q. But if he didn't know the character of the water; then could he ascertain it, in your judgment?

A. That would depend upon the results of his analysis.

Q. If he didn't know the character of the water into which the sewage entered, or the character of the sewage that entered the water, in fact didn't know that any sewage entered the water at all, what would have to be the results of the analyses in order to demonstrate the presence of sewage in the water?

3382 A. I should be unable to state in definite terms.

Q. Do you know?

A. Not in definite terms, no sir.

Q. Do you know in indefinite terms or in any terms. Ar you able to answer the question, Mr. Whipple?

A. Yes, I will answer it. If I didn't know the characte of the water originally or the character of the sewage; if obtained from my analysis, results which approached those i character which would ordinarily be obtained by the analysi of sewage I should be able to form a fairly reliable opinion a to the presence of sewage in the water.

Q. What are the results which are obtained by the analysi of sewage, to which you would compare the results from th analysis of the water in order to draw that conclusion?

A. Do you mean the character or the amount?

Q. I mean the character and the amount and all the el ments that would enable you to form an accurate judgment, scientific judgment.

A. Read that question again.

Q. (Question repeated.)

A. I should compare the qualities which have been alread enumerated.

Q What are they?

3383 A. In so far as I could obtain them.

Q. What are those qualities?

A. Namely, the amount of organic matter as shown by th albuminod ammonia, the character of the organic matter a indicated by the free ammonia, the nitrites and the nitrates; th amount of total solid matter, the matter in suspension, the chl rine, the hardness, the prevalence of certain particular specie of bacteria such for example as the bacillus coli, the number o bacteria, the color, the presence of certain microscopic orga isms, etc.

Q. To which one of these elements would you attach th greatest importance in ascertaining the presence of sewage i water?

A. That would depend upon circumstances.

Q. What circumstances?

A. It would depend upon the character of the water int which the sewage was discharged.

Q. Suppose you didn't know that. You take the wat fter these things have occurred, and analyze it, and you find hese elements in it. You know nothing about the source of he water. To which one of these elements would you attach he greatest significance as evidencing the presence of sewage?

A. If you will excuse me, I didn't quite finish my answer
384 to the previous question.

Q. You may go ahead Mr. Whipple; I didn't mean to nterrupt you.

(Answer to the previous question read to the witness.)

A. (Continued.) And upon the time that might have lapsed between the collection of the sewage and its analysis.

Q. (Last question read to the witness.)

MR. TODD: My question refers to an analysis made of ater itself, without any knowledge of what took place miles bove, as to the character of the water into which the sewage mptied and the character of the sewage which emptied into he water, but the analysis shows the presence or absence of hese elements which you have enumerated.

Now my question is to which one of these elements do you ttach the greater significance in order to demonstrate the presence of sewage pollution in the water thus analyzed?

A. There is no one element to which I should attach speial prominence.

Q. Suppose some of these elements were absent, could you onclude sewage pollution?

A. I might be able to conclude the presence of sewage polution, but my judgment would be to that extent, or to the existence of the pollution, less reliable.

Q. What significance has the presence of albuminoid amonia in water as to determining the presence of sewage or not.

3385 A. It serves as a measure of the amount of undecomposed organic matter present, but taken by itself, it cannot be used to determine the amount of sewage pollution present.

Q. The presence of sewage pollution was my question—not the amount.

A. That's what I mean.

Q. You said the amount.

A. I meant the presence.

Q. What is albuminoid ammonia?

A. There is no such substance.

Q. What?

A. There is no such substance.

Q. There is no such substance as albuminoid ammonia?

A. No sir.

Q. Then when you used the words "organic matter" know by the name of albuminoid ammonia, you were referring to substance that did not exist, were you?

A. I do not think I used the expression "organic matt known by the name of albuminoid ammonia."

Q. You used the words "albuminoid ammonia," didn you?

A. Yes sir.

Q. What did you mean by it if no such substance exist

A. It is simply a form of expression for describing th amount of organic matter present.

3386 Q. It is merely, then, an expression that has a quant tative meaning as applicable to something else, and ha no meaning in itself, has it?

A. It is a form of expression for the substance, and is n the name of the substance itself.

Q. Do chemists employ terms that have no significance?

A. I should say not.

Q. Chemistry is an exact science, isn't it?

A. Fairly so.

Q. And albuminoid ammonia is not a name that attach to any particular element known in chemistry, is it?

A. No sir.

Q. If you take the white of an egg and allow it to decon pose, isn't the product of decomposition known as albumino ammonia in chemistry?

A. Not as we use the term in water analysis.

Q. You use different terms in chemistry for elements whe you analyze water, from what you use when you analyze oth elements and substances?

A. We sometimes do.

Q. Is this word "albuminoid ammonia" a trick word of e profession?

A. No sir, I shouldn't call it a trick word.

Q. Isn't albuminoid ammonia a chemical element the same as nitrites and nitrates? 87

A. Not as we understand it in water analysis.

Q. Is there any such thing as free ammonia in water anal-is?

A. We have that expression.

Q. Does that expression mean anything?

A. I think it does.

Q. What does it mean?

A. If the water is said to contain free ammonia, we mean at the water contains ammonium compounds which are such upon boiling the water the ammonia will be driven off in such way that its amount can be determined.

Q. Well, that is a name given to a chemical substance, is not, free ammonia?

A. Ammonia is.

Q. Free ammonia?

A. It stands for the ammonium compounds present, as I ave described.

Q. Is there any difference between the use of the term free mmonia, to water, in defining an element, than in using the ords "albuminoid ammonia" in defining the element?

A. Neither of them are the names of substances actually xisting in the water, but rather they stand for substances ex-sting in the water.

Q. They stand for substances existing in the water?

388 A. Yes sir.

Q. And are used synonymously with the substances them-elves, are they not?

A. Practically so, for practical purposes in water analysis.

Q. What are nitrites, are they a substance, or the name for substance?

A. It is both.

Q. What are nitrates?

A. They are also a substance which may exist in water.

Q. From what source do you get what is known as fr ammonia in water?

A. Sometimes from organic matter from decomposition; a other times by the reduction of nitrites or nitrates.

Q. By what?

A. From nitrites and nitrates.

Q. Can you get free ammonia by the reduction of nitrit and nitrates?

A. You can get the nitrogen of the ammonia.

Q. Can you get free ammonia. Can you answer that question, Mr. Whipple?

A. Oh yes.

Q. What is your answer?

A. You can get the nitrogen of free ammonia as the expression is used, in water analysis.

3389 Q. You can get free ammonia from nitrates and nitrites

A. I said you could get the nitrogen of free ammonia, a the term is used in water analysis, from the nitrites and nitrate

Q. My question is, can you get free ammonia from nitrite and nitrates. Do you know?

A. You can, if there are no compounds in the water whicl would unite with the free ammonia, to form ammonium compounds.

Q. Is it not a fact that when you get nitrates, the proces of purification has been completed, and what is known as th nitrogen cycle has been perfected?

A. If we start with organic matter as represented by albuminoid ammonia, and if— Repeat the question.

Q. (Question read.)

A. And if this decomposition progresses, we may get al of the nitrogen compounds into the form of nitrates.

Q. From what is albuminoid ammonia derived, from animal or vegetable origin?

A. The substance for which the term albuminoid ammoni stands, may be derived either from animal or vegetable matter. In fact, it may be animal or vegetable matter.

Q. When you find the presence of albuminoid ammonia ir water does the science of chemistry enable you to ascertai

whether that albuminoid ammonia comes from animal or
390 from vegetable origin?

A. No sir.

Q. That is a chemical impossibility, is it not?

A. With our present methods of determination or analysis, ith the substances represented by the term of albuminoid am- ionia, it may be derived from or may be either animal or vege- able matter.

Q. And is it not a fact, Mr. Whipple, that it is beyond the ale of chemical science to ascertain whether the presence of lbuminoid ammonia in water is derived from animal or from egetable origin?

A. From any methods of chemical analysis with which I m familiar, it is impossible to tell whether the substance rep- esented by the term albuminoid ammonia, is derived from ani- nal or vegetable matter.

Q. Then, if that fact remains in doubt, the presence of ree ammonia which is derived from albuminoid ammonia by he operation of the an-aerobic bacteria upon it, is also in doubt, s it, as to its origin?

A. Repeat the question.

Q. (Question repeated)?

.Q. As to whether vegetable or animal?

A. Repeat the question.

(Question repeated.)

A. The origin of the free ammonia which may be present,
391 whether from vegetable or animal matter, can not be definitely determined, although if the amount of free am- nonia is high compared to the amount of albuminoid ammonia ound, there is, to some extent, more reason to expect that it ame from animal matter, using the terms free ammonia and al- uminoid ammonia as standing for the substances.

Q. Would that be a scientific fact, a scientific demonstra- ion?

A. I shouldn't say that it rises to the dignity of a scien- ific demonstration.

Q. It would be a guess, wouldn't it?

A. No sir, I shouldn't call it a guess.

Q. Anything that falls below the dignity of a scientifi demonstration, you would characterise it how, as a scientist?

A. I might use the term "estimate."

Q. It is merely an estimate which doesn't arise to the dig nity of a scientific demonstration, is it?

A. That is probably a fair statement.

Q. And it is as liable to be wrong as it is to be right, i it not?

A. No sir, I would say it would be more likely to be rig than it would be to be wrong, but I couldn't say how much mor

Q. Well, would it be sufficient for you, as a scientist to pu
yourself on record as saying that you could tell by th
3392 quantity of free ammonia in the water, whether it cam
from animal or vegetable origin?

A. No sir.

Q. You understand we are dealing here with scientifi facts and in my questions that's what I want to keep in ev dence.

(No answer.)

Q. Now that which is true of free ammonia is true nitrites and nitrates, is it not, as to the origin, whether anima or vegetable?

A. Not in the same sense, because nitrates may come fro substances of mineral character.

Q. Nitrates coming from substances of mineral characte

A. I say they might.

Q. In water, what do they come from?

A. They might there.

Q. Is it not a fact that when free ammonia becomes oxidiz by the operation of these bacteria, so-called, that it is convert into what is known as nitrites, and the nitrites in turn whe operated upon by the same kind of bacteria, known, I believ as an-aearobic, the nitrites are converted into what is known nitrates?

A. It is a fact that the substances which you describe
free ammonia, that the nitrogen of that substance may b
3393 come changed to nitrites, and afterwards to nitrates und
the influence of certain bacteria.

Q. Then if you found nitrates in the water analysis, these itrates may come not only from animal and vegetable, but also rom mineral origin?

A. They might.

Q. Then when they come from mineral, does that come from ewage of any kind?

A. Not unless the sewage contains minerals from which hey came.

Q. But generally it doesn't contain mineral matter does , except chlorine?

A. Sewage contains mineral matter besides chlorine.

Q. Well, if these nitrates should come from mineral, would ou say that they came from mineral sewage, or from mineral utside of the sewage?

A. I couldn't say definitely without knowing whether any f the sewage entered the water, or whether the water in any ay came into contact with minerals which would give up nirates.

Q. But the minerals do not come from the vegetables?

394 A. Speaking popularly, minerals do not come from vegetables, but in so far as nitrates represent mineral matter, these might be derived under the action of bacteria, from egetable matter.

ADJOURNED until 2:15 P. M. same day, Friday, May 15, 903.

395 Southern Hotel, St. Louis, Missouri. 2:15 P. M., Friday, May 15th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same council representing he respective parties.

GEORGE C. WHIPPLE,

esumed the stand for further cross-examination by Mr. Todd, nd testified as follows:

Q. Mr. Whipple, if nitrates are found in the chemical analyses of water, does their presence there indicate from what ource they have their origin, whether vegetable, animal or nineral?

A. No, sir; not simply because they are found there.

Q. Does the presence of albuminoid ammonia, free ammonia, nitrates and nitrites of themselves, whether in large or small quantities, determine the presence of sewage pollution?

A. Not necessarily.

Q. You stated among these different elements in the analysis of water, hardness of water; that term—what do you mean by that chemically speaking?

A. It is a term which we use in the chemistry of water to
3396 define the amount of those substances present which will
decompose soap, and is represented chiefly by the carbonates and sulphates, nitrates, chlorides, etc., of calcium and magnesium.

Q. The hardness of water is an attribute which is derived chiefly from mineral origin, is it not?

A. Yes, sir.

Q. It is not derived from sewage pollution when the sewage is from the fecal and urine discharge of man, is it?

A. It might be to some extent.

Q. Well, to an extent so limited that you would not consider it, would you?

A. I should usually consider it.

Q. To what extent would you consider it?

A. I could not express that in definite terms, but I might say that that would be a smaller fact to be considered than most of the other elements which I have mentioned.

Q. Of itself would it decide sewage pollution?

A. Certainly not.

Q. Have you ever examined the waters of the springs in the Ohio valley?

A. No, sir; not personally.

Q. Nearly all spring water is what is known as hard water, is it not?

A. Speaking in general terms I should say yes, but I
3397 know of some localities where the spring water is con-
sidered soft.

Q. Where there are rock deposits—mineral deposits?

A. For example, lime deposits.

Q. In limestone regions the water is what is known as hard water, is it not?

A. Yes, sir.

Q. Now, total solids and solids in suspension, those solids may come from what sources?

A. They may be of mineral origin or of animal or vegetable origin.

Q. Is there anything in the attributes pertaining to the solids themselves which would indicate their origin?

A. That would depend upon the character of the solids rather than the amount of the solids.

Q. That is what I mean; is there anything in the solids in suspension or solution that would enable you to determine scientifically—when I use the word "scientifically" I mean within the scope that you have qualified as an expert—

A. Perhaps you had better read it again; I think I get your meaning—

Q. (Question read)—the source from whence the solids are derived?

A. Well, that would depend upon what I found to be the character of the solids—of the suspended solids, or of the total solids. 3398

Q. Well, in the analyses that you have made in connection with this investigation, was anything disclosed as to the character of the solids in solution or the solids in suspension?

A. To which analysis do you refer?

Q. The one—take complainant's Exhibit 1 for identification.

A. I guess I will have to look at it, I don't know just what that was.

Q. Well, while we are waiting for that I will ask you another question. Do you recall whether any of the characteristics such as you would want to know, were disclosed in those analyses?

A. Yes, sir; for instance, if we consider the total solids which would naturally include the hardness and the chlorines, etc., I should want to know—

Q. You don't get my question, Mr. Whipple. My question is, did the analyses which you have before you, complainant's Exhibit 1 for identification, disclose the character and nature of solids in suspension and solids in solution aside from quantity?

A. Yes, sir; there were certain facts shown on this tabl which would give me a certain idea as to the nature of the soli matter—of the total solids and the suspended solids.

Q. Will you indicate what characteristics, aside from quantity, are disclosed by those tables as to the characteristic
3399 of the solids in suspension and the solids in solution?

A. If we consider this sample, on the first line of thi sheet numbered 5785, I see that the total solids, or the tota residue on evaporation, as it is called here, is 2070. Now fro my general knowledge, I know that in those total solids would b included the chlorines, which is stated as 17½ parts per millio and the alkalinity which is stated as 120 parts per million, an there are figures given for the nitrogen as albuminoid ammoni free ammonia, nitrites, nitrates, etc., all of which would necessarily be included under the head of total solids.

Q. So, then, under the head of total solids, there is chlorine, albuminoid ammonia, nitrites, nitrates and free ammonia

A. I mean that those substances which you mentione would be included in those total solids.

Q. Are the proportions of those substances given in th total solids?

A. Not in the figure which represents the total solids; don't know as I quite catch you; I am trying to understand you question.

Q. The point is, do the elements which you find there o the table—albuminoid ammonia, chlorine, nitrites, nitrates an free ammonia, are they the component parts of the total solid in a given sample of water?

3400 A. They form a part of the total solids, but the sum o these elements named, does not necessarily equal the tot sum.

Q. Now, from the table and analyses that you have befor you, are you able to tell whether that sample of water wa sewage polluted or not, or whether those elements are derive from animal or from vegetable origin?

A. I am not able to tell either of those things from the figures, as I find them right here, considering nothing else, tha these figures.

Q. That is what I want to get at. Now, what other el ments would you consider in connection with those analyses in order to determine whether the chlorine, albuminoid ammonia, free ammonia, nitrites and nitrates, were derived from animal or vegetable origin, as indicated in those tables marked Complainant's Exhibit 1 for identification?

A. I should want to have more information—more practical information in regard to the source of this sample and the place from which it was derived.

Q. Does that table indicate where that sample was taken?

A. It is taken at Fort Bellefontaine, in the Missouri river.

Q. That gives the locality of the sample, as to place and the river from whence it was taken?

3401 A. Yes, sir.

Q. Now, what else would you want to know?

A. I should like to know the character of the watershed from which this sample of water was derived, with reference to the existing pollutions.

Q. Is that the answer?

A. Yes, that is the answer.

Q. Then if you did not know the character of the watershed you could draw no conclusion from that, as to whether it was sewage polluted or not, could you?

A. I don't think I could from this particular sample; I think the analysis is of such a character that it would be difficult to tell from analysis itself, whether or not this water were sewage polluted.

Q. Assume, Mr. Whipple, that the sewage of Kansas City, Kansas, and the sewage of Kansas City, Missouri, and the sewage from slaughterhouses and cattle sheds located at those two places, emptied into the Missouri river about 400 miles above this point, would that enable you to draw any conclusion as to whether that water was sewage polluted or not?

A. Now, if you will read that once more; there are one or two points there—

Q. (Question read.)

A. Those facts would indicate that this water might per-
3402 haps be sewage polluted, except in so far as the effects of the pollution which you have mentioned, may not have been interfered with by processes of sedimentation, etc., between

the point of pollution and the point where this sample was collected. I should have to balance a number of different conditions in order to arrive at such a result.

Q. If it should appear that several thousand acres of lan upon the Missouri was overflowed or inundated, and the water of the Missouri passed over those lands, and that the river wa serpentine in its course—winding, would that information added to the assumptions about the Kansas Cities, shed any light upo the conclusion to be derived from that examination?

A. Just read that question.

Q. (Question read.)

A. The added information which you mention would enabl one to make a better judgment of the probability of this wate showing the effects of pollution at the point where the sampl was taken, but even this information would not be sufficient t give an absolute opinion on this matter without considerin such questions as dilution, sedimentation, etc., which I mentioned.

Q. Would not the overflow of this land aid sedimentation

A. In so far as by the overflow of the land the water wa
allowed to come to a position of quiescence, it might ai
3403 sedimentation; but on the other hand, during the proces
of overflowing, the land, it might add to the water sediment derived by overflowing the land, and thus make the wate more turbid, or contain more suspended matter than before.

Q. Well, what would be your opinion as an expert, as t whether the sewage from Kansas City would purify itself i going 400 miles, to Fort Bellefontaine, the point where tha sample was taken?

A. Just read that question.

Q. (Question read.)

A. That would depend upon the amount of dilution whic the sample—which the sewage received, the amount of sedimentation which took place in the stream; the action of microscopi organisms and bacteria upon the sewage, etc., and when I spea of this as a process of purification—and when I speak for example of dilution as being a process of purification, I woul not imply that it was a change which was brought about in th matter of the sewage, but rather that an equal volume of wate contained less of the sewage matter than before, assuming of course, that the water used in dilution was purer than the sewage.

Q. Are you acquainted with the character and volume of the sewage of Kansas City, Missouri, and Kansas City, Kansas?

A. I am not acquainted with its character, and I am not
3404 acquainted with its volume, except in so far as in general
that may be indicated by the population of the city.

Q. Are you acquainted with the character of the population and the sewage of the cities that empty into the Missouri river above Kansas City?

A. I am acquainted with the number of inhabitants in the cities of over 4,000 inhabitants in the territory you mention, but I am not personally acquainted with the character of the sewage.

Q. Would you call the water of the Missouri river above Kansas City a potable water?

A. I have not the means for answering your question, for in the first place I have no analytical data concerning the water of the Missouri river above Kansas City; and furthermore the term "potable" does not have to me a definite and well defined meaning.

Q. A pure water, then?

A. To a lesser extent the same is true of that term.

Q. A sewage polluted water?

A. How was that phrase there—

Q. Do you consider the water of the Missouri above Kansas City a sewage polluted water?

A. In so far as the sewage of the cities dwelling upon the
water shed of the river above that point enters the river,
3405 I should consider it as a sewage polluted water.

Q. Suitable for drinking purposes?

A. That I am unable to state from the facts which I have at hand.

Q. You stated in a previous answer—I don't know that I quote you right, but if I don't, you correct me—that whether the Missouri river purified itself of the sewage of Kansas City, would depend upon the amount of pollution, sedimentation, and the action of bacteria, before it got to Fort Bellefontaine. Does that correctly state what you meant?

A. Perhaps you had better read that again.

Q. (Question read.)

A. What I meant was whether certain elements of the sewage as it entered the stream at Kansas City—was it?

Q. Kansas City, Kansas, and Kansas City, Missouri?

A.—actually reached the Fort Bellefontaine, would depen among other things upon the dilution—what was that quesio again?

Q. (Question read.)

A. (Continuing) whether it reached Fort Bellefontaine i quantities sufficient to be detected, or to have any effect upo the water when used for drinking purposes, depended upo dilution, sedimentation. the action of bacteria—I would sa the possible action of bacteria and microscopic organisms 3406 or other such natural agencies and I understand that yo are barring out any artificial actions which might be introduced?

Q. Yes. What would be the amount of dilution necessar to meet the requirements of your answer—what proportion o water to sewage?

A. That would depend upon the character and the amoun of the sewage and also perhaps upon the relative effect of som of the other agencies mentioned, including, for example, th time of transit of the water from the one place to the other. What was that answer?

(Answer read.)

THE WITNESS: Will you read that question again?

Q. (Question read.)

A. Well, I don't know that I need to add anything furthe to that.

Q. Do you know what the amount of dilution of the sewag of Kansas City is, when it enters the Missouri river at Kansa City?

A. No, sir; I don't know the exact amounts of dilution, because I don't know the volume of the sewage and I don't kno the volume of the stream at that point.

Q. Do you know the amount of sedimentation that take place?

A. I don't know the actual amount of sedimentation whic

takes place, but speaking broadly, I know that the Mis-
3407 souri river is a comparatively rapidly flowing stream;
I know that its flow varies at times, and it would be my
udgment that at times sedimentation might occur; at certain
imes and places sedimentation might occur, to some extent, and
t other times the sediment deposited might be taken again into
uspension and carried down stream; therefore I am unable to
tate the combined effect of sedimentation, and what would be
he opposite, the condition which you might term the scouring
f the stream, or the removal of the sediment.

Q. Do you know the rate of the current of the Missouri iver?

A. I have in some notes which I think I can find, some ap-roximate figures.

Q. Approximately four miles an hour, is it not?

A. I don't recollect exactly. I should rather refer to my otes.

Q. I wish you would.

GENERAL CROW: You mean in the mean stage of water, r average?

MR. TODD: Yes.

GENERAL CROW: That is a pretty fast current, isn't it?

MR. TODD: That is what Dr. Teichmann testified to, I hink.

THE WITNESS: I have here some notes which state that
he mean velocity expressed in feet per second, of the Missouri
river from Plattsmouth, Nebraska, to the Mississippi
3408 river, the time of average flow is about four and one-half.

GENERAL CROW: Four and one-half feet per second?

A. Yes, sir; four and one-half feet per second. Under hat we may term an ordinary low flow, though not a minimum low perhaps, it is about 2.7 feet per second, while under an rdinary high flow, though perhaps not under extreme condi-ions, about 6.5 feet per second.

MR. TODD: Is that figured out into miles?

A. No, sir; it is not.

GENERAL CROW: That only makes it three and one-uarter miles, at an average stage—it wouldn't make that; it ould make about three miles.

THE WITNESS: One foot per second is equal to abou .68 of a mile per hour—do you want me to find that for you

MR. TODD: No, I think I have what it will approximat

Q. If it should take seven days from Kansas City to For Bellefontaine, for the water to come that distance, what is your opinion as to whether the sewage from Kansas City, Missouri and Kansas City, Kansas, purifies itself by the time it gets there?

A. I could not give a general answer to that as applied to the sewage as a whole, because certain things might affec certain elements of the sewage, and not affect the other elements.

3409 Q. Have you any opinion as to whether the water of the Missouri river at Fort Bellefontaine, is sewage polluted or not?

A. In so far as the population of the watershed on the Missouri river above that point is concerned, or in so far as the sewage of that population is concerned, I believe it to be sewage polluted water to the extent mentioned.

Q. To what extent?

A. In so far as the amount of sewage from the populatio dwelling upon the watershed enters the water of the Missour river, and in so far as the ingredients of this sewage are no destroyed or diluted or otherwise removed from the water o the river before it reaches Bellefontaine.

Q. Then it is your opinion that all the sewage that i eliminated does not exist when the waters get to Fort Bellefontaine, is it?

A. Why, if the sewage is really eliminated from the water it does not get to Bellefontaine.

Q. That is a kind of an axiom, isn't it?

A. I suppose that you may call an axiom—that is, to illustrate: If you put a thing into water and take it out again, i isn't there.

Q. And do you know how much of the sewage that enter the water at Kansas City is taken out or eliminated chemi-
3410 cally or in any other way, by the time it gets to Fort Bellefontaine?

A. I don't know exactly, but I don't think that is a subjec of exact determination, and I don't think that the sewage as a whole can be subjected to such a determination. As I explained before, what might occur to one constituent of the sewage might not occur to another constituent of the sewage.

Q. You stated that the color of the water was one of the elements among the numerous elements that you have enumerated. To what is color due, to vegetable or animal origin, in the term that you used it?

A. Speaking broadly, the color of the water which shows itself as a brownish stain, is due to vegetable matter in solution.

Q. Then that color does not indicate sewage pollution, does it?

A. No, sir.

Q. You spoke of the presence of the bacilli coli communis; what does that indicate—sewage origin?

A. I could not state definitely that it does indicate sewage origin. It is believed by many scientists today that this organism may be found in waters where pollution may be remote. This organism is a common inhabitant of the human intestine, present in large numbers in ordinary sewage, and this organism is found so often and in such quantities in waters which are 3411 known to be sewage polluted and which is found so rarely or in such small quantities in waters which are presumably not polluted, that most bacteriologists are agreed that the test for the presence of this organism is a most important one to be considered in determining whether or not the water is sewage polluted.

Q. What do you hold as a scientist, upon that question, and as a bacteriologist, aside from what those people hold that you have referred to?

A. I hold that if this organism is constantly present, or is very often present in a water, and if this organism is present in such numbers that we can readily determine its presence by analyzing one cubic centimeter or less of the water, it is probable that this is an indication of contamination by fecal matter. I do not believe that the test is an absolute test, but I consider it a valuable one to be interpreted in connection with the rest of the analysis.

Q. Where is this bacilli coli communis found?

A. It is found most commonly in the intestines of man and certain animals.

Q. What animals?

A. For example, the cow, the horse, the pig, and I think birds, and speaking generally, in warm blooded animals.

Q. Suppose that a stream contained a great number of fish, like the Illinois river, and this organism or bacteria coli communis was found in the fecal matter of fish, would the 3412 presence of the bacillus coli communis in such a water be any evidence of sewage pollution?

A. Just read the question again.

Q. (Question read.)

A. It is my judgment that the presence of the fish, even though the bacillus coli communis might be found in their intestines, would not materially influence the interpretation to be made from the results of the coli test of the water.

Q. Why?

A. Because it has been my experience that the intestines of fish do not ordinarily contain this bacillus, and that if this bacillus is found there, it is a case where the bacillus has been derived from the water, and I base my judgment upon considerable personal work which I have done in that direction.

Q. If the bacillus coli communis was found in fish in the Missouri river, would you disregard its presence there in the fish in considering the coli communis in order to ascertain sewage pollution?

A. So far as the presence of the bacillus coli communis in the intestines of a fish influences the presence of the coli communis in the water.

Q. Have you finished that?

A. Yes, sir.

Q. Read my question. (Question read.)
You would disregard it, or regard it?

3413 A. I meant that I would disregard its presence in the intestines of the fish so far as any interpretation were made from the presence of the coli communis in the water.

Q. Have you personally investigated this quesion of coli communis in fish?

A. Yes, sir.

Q. To what extent?

A. I can't give you a definite answer, but I can remember a number of years ago that I spent several weeks in investigating the contents of the stomach and intestines of a number of different kinds of fish with respect to the presence of this bacillus coli communis, and I came to the conclusion that this organism did not live in the intestines of the fish as it lives in the intestines of a warm blooded animal, as for example, a cow, but that the occasions when I did find it were so rare that I was safe in concluding that they came from the water in which the fish were found.

Q. About how many fish did you examine?

A. I can't say definitely, but certainly two or three dozen.

Q. Did you examine any fish of the carp variety?

A. No, sir; I did not examine any carp.

Q. Were the fish you examined fresh water or salt water fish?

A. Fresh water fish.

3414 Q. What fish were they?

A. I don't know that I can tell you exactly, but I remember perch and pickerel and hornpout and a lot of smaller fish, and I remember those fish that we call pumpkin seeds in New England; some of the common fish which were found in our New England ponds.

Q. Now, are there any micro organisms, such as you have described, in the tables, submitted, found in the intestinal discharge of man, in the feces or the urine?

A. I have never found any microscopic organisms in the urine of man, but I have found the remains—if you can call them remains—or the cell walls of diatomes, for example, in the feces of man, and I attribute their presence there to the fact that they have taken these organisms into their stomach, and that these cell walls being of comparatively indestructible character, were not injured in passing through the intestinal tract.

Q. But was there anything in connection with these microorganisms to identify them as having passed through the alimentary canal of man?

A. There was not.

Q. And when they had made this passage, were they alive or dead?

A. I cannot remember exactly, but I imagine that the or-
3415 ganisms themselves were dead, although I cannot say.

Q. What organisms—what micro-organisms found in water demonstrate sewage pollution from the fecal discharge of man?

A. I don't know of any that absolutely demonstrate its presence, but there are certain microscopic organisms or micro-organisms which are so often associated with sewage, that in a very general way they do serve as an index of the presence of sewage, but I wish to be understood as saying that they indicate it only in a very general way.

Q. So general that you could not assert that a stream was sewage polluted because these organisms were found in the stream?

A. No, sir; I could not assert it from their presence there, barring all other considerations.

Q. Now, Mr. Whipple, we have gone through all the elements which you have indicated that the analyses would show. Are any of these elements taken separately or combined, that demonstrate their origin to come from the fecal discharge of man or the urine discharge of man, if found in waters?

A. Just read that once more.

Q. (Question read.)

A. There are none of the elements which you have mentioned taken singly, that would demonstrate that fact.

Q. Or taken collectively?

3416 A. And even when taken collectively, they are not always
able to demonstrate their origin as coming from the urine or feces of man, but taken collectively and making comparisons with what we know of their character and amount in sewage, we are sometimes able to judge as to whether or not a water may be polluted with sewage which presumably contains the dejecta and urine of man.

Q. Is that an assumption or a scientific demonstration?

A. I wouldn't consider it as a scientific demonstration, but I would regard it as more than an assumption; I would regard it as a fair estimate of the conditions.

Q. Does the words "fair estimate" in the sense you use it, rise to the dignity of a scientific demonstration?

A. No, sir; I wouldn't call it a straight scientific demonstration, but I would consider it what you may call a reasonably correct judgment.

Q. And that judgment that you define as reasonably correct judgment, is liable to be mistaken, is it not?

A. Yes, like all human judgments.

Q. And differs from a scientific demonstration in the fact that the scientific demonstration is not liable to be mistaken; is that right?

A. That depends upon just how straight an interpretation you wish to give to a scientific demonstration.

3417 Q. Well, isn't a scientific demonstration, in the way that you use it as a scientist—not the way that I use it, because I know nothing about science—an accurate determination of a fact, and without any elements of doubt connected with it?

A. Considering that it brings about an accurate and infallible result, I say that my reasonably correct judgment is not as high as an absolutely infallible result.

Q. Is an estimation, in the sense you use it, a scientific determination of a fact in regard to stream pollution?

A. Perhaps, in the straight sense, in which you may mean.

Q. I want to know what you mean, if you will excuse me for suggesting it, as you are testifying and I am merely asking.

A. Perhaps not in the strictest possible sense, but I believe what you may call a scientific estimate may often be considered as giving us reasonably correct results.

Q. That is true in the absence of science, when the judgment of a man of ordinary common sense attempts to give an opinion upon a state of facts, is it not?

A. The accuracy of the judgment will depend upon the basis upon which that judgment is founded, and upon the character of the person who makes the judgment; his experience on the subject upon which the judgment is made, and such general conditions as that.

3418 Q. Then is this proposition true, that where science is unable to enter a demonstration, the judgment of a scientist can form an estimate which is reliable?

A. No, sir; I wouldn't say that was true as a general proposition.

Q. Is the science which you bring, by virtue of experience, to fortify your opinions in this case, any less accurate than the science of engineering, that constructs a bridge, or of the surveyor that plots a piece of ground?

A. I don't think I can answer that question by yes or no, because the science includes so many—because the two sciences assume so many facts. For example, there are certain determinations in chemistry which can be made with great accuracy and with as small limits of error as certain determinations made by the engineer or the surveyor, while there are other parts of the science where the limits of accuracy may not be as great, just as I concede may be the case the other way around.

Q. Then when scientists get to that point where they cannot demonstrate by analyses, they can merely approximate the truth by an opinion or an assumption, is that right?

A. No, sir; I don't think that is right. When they get to a point where they cannot make an absolute determination, they obtain the best available data which they can get, and make the best scientific judgment which they can from this data. They do not abandon all data and simply make a guess.

3419 Q. You wouldn't call that judgment scientific, though, would you?

A. I would call it a judgment based on scientific facts. To that extent it would be a scientific judgment, perhaps.

Q. Now, in the bacillus of typhoid, how many of these organisms are discharged by one typhoid patient?

A. I couldn't say definitely, although I have at times seen figures which pretend to give the numbers of typhoid bacilli found in the feces and dejecta of typhoid patients and in the urine discharged by a typhoid patient, and I have myself made determinations of the number of typhoid bacilli in the urine of a typhoid patient, where I found a number of thousands of such bacilli to a cubic centimeter, but I cannot give the exact figures either from memory or from notes.

Q. Well, as a general statement, isn't it true that the numbers are enormous?

A. They are certainly enormous.

Q. And the number of these organisms from the discharge of one patient, would be sufficient to create an epidemic, wouldn't it, if the waters of that stream were drunk?

A. Under certain conditions.

Q. By the cities?

A. Under certain conditions.

Q. What conditions?

3420 A. That would involve a considerable series of conditions, among which you may consider the vitality of the organisms originally, the rate at which they might die out in the water, the relation of the number of organisms to the amount of water into which they enter; the amount of sedimentation which might occur in the water between the times when they enter the water and the times when that sewage reached the people who drank the water, and if sedimentation occurred, the chances of these organisms being again carried into the water and thence borne to the places where the people drank the water, the possible influence of the microscopic organisms, the possible influence of sunlight and such conditions.

Q. So it depends upon numerous conditions?

A. It depends upon numerous conditions, yes ,sir.

Q. Do you know how long the bacillus of typhoid will live in sewage contaminated water running in a river?

A. I don't know definitely.

Q. Do you know of any scientist who knows or who has asserted it as a fact?

A. I don't know of any scientist who actually knows. I know the bacillus of typhoid fever will live in sewage polluted water, but scientists have made laboratory experiments to determine that fact and they have arrived at certain conclusions. Do you wish me to enumerate any further?

3421 Q. That is an answer to my question, and is as far as I care to have you go. Do you consider conditions in the laboratory, where experiments have been made, similar to conditions that exist in a running stream, sewage polluted?

A. No, sir; I do not.

Q. Do you know whether there has ever been a test of typhoid germs in sewage polluted water made in the laboratory?

A. Yes, sir.

Q. You know how long they would live in that water, subject to sunlight and air and motion, do you?

A. I do not recall the experiments made to determine the longevity of the typhoid bacillus by laboratory experiments in water, where the question of motion was taken into account, but I know of experiments which have been made in sewage polluted waters where the questions of sunlight and air were taken into account. In fact, I know of a number of such experiments which have been made and the longevity was found to vary from a period of some weeks to a period of some months. I cannot at this moment give the exact results reached by those observers. I have also made experiments on the subject myself.

Q. Were those experiments conducted in the laboratory, similiar to conditions that exist in running streams?

GENERAL CROW: Which do you refer to; the ones he made himself?

3422 MR. TODD: Yes, and the ones you have testified about?

A. No, sir; the conditions were not the same as would exist in running streams in all respects.

Q. Do you know of anyone who has ever discovered the germs of typhoid in running waters?

A. I know people who have claimed to have discovered the germ of typhoid in running waters, but I am unable to state whether they actually did discover that germ in running waters or not. In the earlier stages of bacteriology when species were not studied as carefully as they are today, certain results were obtained and put forth by bacteriologists, which would hardly be credited in the present state of the science, and yet there are on record cases where apparently the results indicate that the typhoid fever germ was discovered.

Q. What is the name of that test that has been recently discovered for the germs or bacteria?

A. I don't know just what test you refer to.

GENERAL CROW: Do you mean the physician's test, the Widal test?

MR. TODD: Yes. Has anyone discovered the germs of typhoid in running waters since the discovery of the Widal test?

A. I am not exactly sure, but I think that one or two such discoveries are said to have been made.

3423 Q. Do you know who they were or anything about it?

A. I don't know anything definite, but it is my impression that Dr. Wesbrook of the University of Minnesota, who is the bacteriologist for the State Board of Health of Minnesota, found an organism which appeared to be a typhoid bacillus, and if I am not mistaken that organism did give the proper test with the Widal reaction, but I cannot confidently state that this is the case.

Q. Has any scientific investigation been made as to the rate this typhoid bacillus dies out in running waters, running sewage polluted water?

A. Experiments have been made to show the rate at which they will die out in water, under laboratory conditions.

Q. But I mean in the natural conditions of rivers?

A. I know of no experiments that have been made in the rivers themselves. I don't see how it is possible in the present state of bacteriology for reliable experiments of that character to be made.

Q. You stated that it would depend upon the rate they died out and the amount of water dilution and sedimentation. What did you mean by the amount of water dilution?

A. What would depend?

Q. Whether the discharge of a typhoid patient in the river, that the bacteria in it would be sufficient to cause an epidemic among people who drank the water of that river, and your
3424 answer, as I remember it was, that it would depend upon the rate they died out, the amount of water in dilution, sedimentation and one or two other matters?

A. Yes sir.

Q. Now in regard to that, what did you mean by the amount of water in dilution?

A. I meant this, that if a certain number of typhoid fever bacilli were put into a certain amount of water and mixed throughout it, and if again, the same number of bacilli were put into a larger quantity of water and thoroughly distributed throughout it; then disregarding all other things, an equal volume of the large quantity of water would contain fewer bacilli of typhoid fever than the small quantity.

GENERAL CROW: Do you mean to say exactly that thing? Now would it contain fewer, or might it contain fewer?

A. I am assuming they would be all equally distributed.

GENERAL CROW: That is what I am getting at. Is that a possible condition, as a matter of information I want to know?

A. I am not stating that as a condition which would occur; I am stating it as a condition which might.

Q. He is asking you the practical question, the effect of dilution; that's the reason I offered the suggestion that I did. Pardon the interruption. I thought you would want a practical answer.

3425 MR. TODD: I want the facts. What is the effect of dilution upon the typhoid bacteria?

A. If we assume that different typhoid bacilli are separated from each other, and that they will be distributed in the water, the effect of dilution is to spread further these organisms from each other, assuming of course a thorough mixture of the water, as I understand you to mean.

Q. Are they separated or are they in clusters when they are discharged through the urine or through the feces?

A. I think that both conditions would prevail.

Q. Is it not a fact that the urine carries more of these organisms than the feces of a typhoid patient?

A. I don't recollect; that would depend upon whether you include the amount of urine, or whether you measure them and compare the number in a cubic centimeter in the one, with the number in a cubic centimeter of another.

Q. By that comparison?

A. I think it would further depend on the stage of the disease. I can conceive that at a certain stage of the disease they might be more numerous in the feces than in the urine, and at the other stage I can conceive that the reverse might be true.

Q. Well, when they get into the water they separate, do they not?

A. I have no doubt that many of them do. I suppose it 3426 is also true, that like other bacteria, many of them remain together in what you call groups, using that word in a broad sense, or may be held together by some force, substance perhaps, so that as a matter of fact they may occur both singly and in groups.

Q. · Do they increase and multiply while in the water?

A. I believe that the best scientific information which we have on that point, leaves us to suppose that after leaving the human system they do not ordinarily multiply in the water.

Q. Are you acquainted with the conditions of the Illinois River between Lockport and Grafton, the physical conditions of the river?

A. I have seen the river between Lockport and Joliet, and I have examined maps and profiles and read reports describing the conditions between Joliet and Grafton; I have never personally seen the river between Joliet and Grafton.

Q. Would the presence of lakes in the river act as settling basins for the purification of the sewage discharged from the drainage canal at Lockport?

A. If such lakes were present on the Illinois river, and if in such lakes the water therein should become more quiescent, than in that of other portions of the stream—Did you speak of typhoid fever bacillus?

Q. Yes. I am speaking of the sewage.

3427 (Question repeated).

A. (Continued) The suspended matter of the sewage, the suspended portions of the sewage might tend to settle more rapidly than in the swifter portions of the stream, but whether this could be called an actual—did you use the expression "purification of the sewage"?

GENERAL CROW: He used the expression "sedimentation and sewage."

A. (Continued) Purification of the water which contained the sewage would depend in part upon what happened to the suspended matter after it had settled, and whether or not the suspended matter was afterwards carried into the stream again, to Grafton.

Q. Is that the end of the answer?

A. Yes sir.

Q. What is your opinion as to whether the suspended matter would settle or not?

A. From what I have learned from reading various reports which describe the conditions of the Illinois River between Lockport and Grafton, it is my opinion that at times such sedimentation may take place.

Q. At what times?

A. At such times as the velocity of the water in the stream was low.

3428 Q. Is it your understanding that the velocity of the Illinois river throughout the year from Chicago to the intake is between eight and ten and a half days?

A. From what I have read concerning the velocities of the stream, I should not place those as the limits for the year.

Q. That is practically the maximum, isn't it, as those rates were taken at practically high flood waters of the river?

A. You mean the maximum rate?

Q. The maximum rates of flow.

A. I should say they were nearer the maximum than they were of the minimum certainly.

Q. When the rate of flow attained that velocity, would you take into consideration the volume of water that spreads out over the surrounding country, overflowing the banks of the Illinois, as sedimentation basins?

A. If we assume that these rates represent conditions approaching the maximum, I should not, speaking generally consider that expansions of the stream which might be due to overflowing the banks, would act continuously as sedimentation basins for any considerable period.

Q. It would add considerable to the dilution of the sewage wouldn't it?

A. The mere fact that the water over-spread the banks would not increase the dilution. It is simply a case of the
volume of the water with reference to the amount of
3429 sewage which affects the dilution.

Q. Assuming that the drainage canal discharged 250,000 cubic feet of water a minute through the Bear Trap Dam, and that the volume of water passing a given point, say Peoria, was 1,000,000 cubic feet a minute, under normal conditions (this is purely hypothetical because I haven't the data), and under flood tide conditions, it would be 3,000,000 cubic feet. Wouldn't the flood conditions add greatly to the dilution of the sewage from the drainage canal?

A. They would add to the dilution. They would increase the dilution of the sewage.

Q. And increasing the dilution of the sewage, wouldn't the sewage be disseminated through the water which overflowed the banks of the Illinois river? That would happen, wouldn't it?

A. A part of the sewage might be carried into the water which overflowed the banks if they overflowed the banks under the conditions which you suppose.

Q. The current in the overflowed sections of the country wouldn't be as swift as it would be in the main channel, would it?

A. Probably not.

Q. And sedimentation would take place there, wouldn't it?

3430 A. That would depend not upon the relative current as much as upon the absolute current.

Q. Well, sedimentation takes place in any kind of a current more or less, doesn't it?

A. I wouldn't say that, no sir.

Q. Now where the river is down to its normal conditions, are you acquainted with the conditions that exist in regard to the dams across the Illinois River?

A. I don't know just what you mean by "in regard" to the condition, unless you mean the average condition.

Q. An average condition?

A. I know that there are some dams across the Illinois river at several places.

Q. Do you know how many—there are four. You know what those dams are there for do you not?

A. I think so.

Q. They are there for the purpose of assisting navigation by raising the water and backing it back up stream. Now when the water in the Illinois river is at normal, and is backed up by these dams, would not the backing of the water up above the dams act as settling basins?

A. If in this water above the dams, the velocities were reduced to such a degree that sedimentation of suspended matter could take place.

Q. What velocity would that be?

3431 A. That depends partly upon the character of the suspended matter and partly upon the velocity of the suspended matter. (Witness referring to book).

Q. Did you write the book?

A. I didn't write this one.

Q. Have you any independent judgment on the point, outside of any authority?

GENERAL CROW: Let him answer the question you asked him.

A. If you ask whether I made any experiments on the subject to determine that fact. I have not.

MR. TODD: Well, have you any judgment yourself as an expert on that proposition?

A. Yes sir.

Q. What is your individual judgment upon the subject as to the speed of a current that would be necessary in order to permit sedimentation?

A. My judgment is that if the velocity is reduced say from a quarter to one-third, or perhaps to a half a foot per second, sedimentation of suspended matter of a certain character might occur. If the suspended matter were coarser, it would settle with greater velocities. I can imagine suspended matter so fine that it would not settle even at those velocities named.

3432 Q. Suppose that the current was a mile in two hours, would sedimentation take place?

A. I think it would, sedimentation of substances of a certain character.

Q. Is there any fixed rule or rate of current when sedimentation might take place?

A. I don't think our knowledge of the subject has reached the point where we can give any strict rule. Properly, I will say that it depends upon the character of the suspended matter and the temperature, and upon a series of conditions, all of which would have to be taken into consideration in formulating such a rule.

Q. If these four dams in the Illinois river in normal conditions, back up the water for a considerable distance above, they would assist sedimentation wouldn't they, considerably?

A. I should say, if I understand your meaning. I think they would allow sedimentation to take place under more favorable conditions than if they were not there to just the extent to which they reduced the velocity of the stream.

Q. And is there a fixed rule as to the amount of sedimentation that will take place at a given velocity?

A. I don't think there is any such fixed rule.

Q. Then it is purely a matter of reasoning, isn't it?

A. No I don't consider it purely a matter of reasoning.
3433 Experiments have been made on the subject, but I don't
think that experiments have been sufficiently numerous or have been made under such sufficiently different characters so that we are enabled to formulate our knowledge in precise statements.

Q. Do you know what the conditions are which obtain in the Illinois river in regard to sedimentation, whether it is the same as in any other river or not, or different?

A. Of course we understand that the laws governing sedimentation of suspended matter would apply to the Illinois river the same as they would apply to other streams, and I know from reports that sedimentation actually is said to take place in the Illinois river at certain places.

Q. Now when you get to Lake Peoria, which is a lake of considerable size where the velocity throughout the channel is one mile in two hours, at the maximum, practically maximum height. Would that facilitate sedimentation?

A. I think that a velocity of one mile in two hours would allow sedimentation of a certain size or kind of suspended matter to take place.

Q. Now by the time that the sewage of Chicago got to Peoria, do you know whether that sewage would be purified or eliminated from the waters or not?

3434 A. Under the conditions which exist, it is my judgment
that the proportions of the sewage, of all parts of the sewage of the city of Chicago would not be eliminated by the time that it reached Peoria.

Q. What part would be,—fifty per cent, seventy-five per cent, or are you able to state?

A. I am unable to state definitely.

Q. Upon what do you base that, doctor, that opinion? Upon what do you base your opinion that the sewage of Chicago is not eliminated by the time it gets to Peoria?

A. I said parts of the sewage, and when I said parts I did not mean a half or a quarter or an eighth or a sixteenth. I meant parts of the sewage, understanding that sewage is not a single substance, but it is composed of various ingredients.

Q. Upon what do you base that opinion?

A. Perhaps I can illustrate that better by example. If we take chlorine, for instance, which is a constituent of sewage, that chlorine would not be affected by sedimentation, for instance, but practically only by dilution, and to that extent the sewage of Chicago would not be eliminated by the time it reached Peoria, but simply reduced in amount by the dilution it might receive.

Q. Well, do you know that from any analytical data, that that is true?

3435 A. I know that there is a certain amount of chlorine in the sewage of the Chicago Drainage Canal, but I cannot recall the amount at this moment.

Q. Let me ask you a question, if I may interrupt you. Do you regard chlorine as an evidence of sewage pollution?

A. Under certain conditions I do.

Q. What conditions?

A. When the chlorine of a water known to be polluted with sewage, is compared with what may be called the normal chlorine in the natural waters, from the region which the water, to which the sewage was added—I do not know whether I am making myself clear or not.

Q. Do you regard chlorine in the Missouri river as an evidence of sewage pollution?

A. From what I know of the existing conditions on the watershed of the Missouri river and from the fact that there are certain salt deposits, there are said to be certain salt deposits on portions of that water-shed, and from analyses which I have seen showing the indication of such salt deposits, or the effect of such salt deposits on the water of the Kaw river, it is my opinion that the chlorine in the Missouri River, in its low reaches, cannot be used as an index of pollution, although part of it may be derived from sewage pollution, because the effect of the chlorine from the salt deposits, would simply mask any chlorine from sewage pollution, and in that 3436 particular case the chlorine could not be used to determine whether or not the water was sewage polluted.

Q. When did you first learn that the Kaw River had salt deposits in it; when was that first brought to your attention?

A. I received a report on the subject a number of years ago. I have the report here somewhere; I can get the date for you if you would like to have it.

Q. I don't care about the date.

A. I have known it as a matter of general knowledge—

Q. How large a river is the Kaw in volume of water?

A. I cannot recall at this moment.

Q. Well, do you know that the Kaw River, is a river from 2000 feet per minute, to 20,000 per minute—cubic feet, is that true?

A. I couldn't tell without consulting some notes.

Q. Well, I will pass by the Kaw.

(No answer).

Q. Is it your opinion, and I believe you stated that the increase in typhoid in the city of St. Louis, is due to the sewage from the drainage canal, from 1900, 1901, and 1902?

A. I think that I stated that under certain conditions which were assumed, the most probable cause of the increased typhoid in the city of St. Louis during that period was due to the sewage of Chicago, meaning by that that was the easi- 3437 est explanation of the increase under the conditions which were assumed.

Q. Does an easy explanation always explain, Mr. Whipple?

A. It doesn't always explain.

Q. Assuming that in the month of November, 1899, there were 482 cases of typhoid and 36 deaths, and in December 116 cases and 37 deaths, and that the number of cases of typhoid for those two months exceeded the number of cases of typhoid in St. Louis for any two months since 1892, and exceeds the number of cases for any similar two months since 1899, and assuming that the number of cases along the towns of the upper Mississippi and the Illinois towns outside of Chicago and outside of the Missouri river towns, was 201 for the year. Do you know of any explanation that will explain the cause of this typhoid epidemic?

GENERAL CROW: I object to it for the reason that it assumes first an impossible condition of affairs, and secondly a condition of affairs that did not exist. First because the number of deaths in the two months attempted to be classified of November and December, 1899, with other periods, is wrong, according to the official returns of the City of St. Louis, and secondly, because the question as to whether or not the witness can explain the cause of the deaths by typhoid in 1899,
has nothing whatever to do with the question as to wheth-
3438 er or not the Chicago sewage has increased the pollution
of the water supply of St. Louis, and for the further reason that it assumes only a period of two months for a test of the City of St. Louis, while assuming a series of years for the entire remainder of the water-shed, which renders it completely unfair, even as a hypothetical question.

A. On the assumptions named, without considering other facts or assumptions, which among other things might include the amount of typhoid fever on the water-shed of the Missouri river and without knowing the time and place where the typhoid fever referred to as existing upon the water-shed of the upper Mississippi and the Illinois river occurred, and other facts of that nature, I cannot form an opinion as to the subject.

Q. If you knew the places where the typhoid existed that made up the 201 cases to which I referred, on the Illinois and Mississippi Rivers, would that assist you in any way in solving this problem?

A. It would be an assistance, yes sir. But it might not be sufficient to enable me to solve the problem.

Q. Well, I will add that to the question. At Centralia, 30 deaths from typhoid fever in 1899.

Dubuque 15. I will state that those are memoranda that I made from the testimony offered in the case. Des Moines 13—

GENERAL CROW: These figures are for the entire
3439 year of 1899.

MR. TODD: Yes and are as follows:

Burlington	8
Minneapolis	71
Keokuk	9
Quincy	6
Hannibal	5
Bloomington	9
Peoria	12
Ottawa	3
Decatur	7
Joliet	5
Elgin	5
Aurora	4

GENERAL CROW: These are towns in Illinois exclusive of Chicago?

MR. TODD: Yes, exclusive of Chicago.

THE WITNESS: That makes 202.

MR. TODD: I have it 201. here. With that additional assumption, does that enable you to offer any explanation?

A. With the addition of that data alone, it would not. There would still be things that I should desire to consider before expressing an opinion.

Q. What other elements would you like to consider?

3440 A. I should like to consider the character and the amount of typhoid fever that existed upon these same watersheds for previous years. The amount of typhoid fever which existed upon the Missouri river water-sheds for previous years and for this year.

Q. Have you heard, or did you hear the testimony here in regard to the typhoid fever at those different places during the previous years?

GENERAL CROW: Did you finish your answer, Mr. Whipple?

A. I said among other things. I didn't name them all. I don't know as I should have named them all.

MR. TODD: I didn't mean to interrupt you.

A. No, I didn't hear the testimony to which you refer, but I have seen some of the figures which I think were introduced.

Q. Well, would those figures help you to solve this problem if you had them?

A. I think they alone, in addition to what you have already stated, and disregarding the questions relating to the flow of the streams at that time, to the possible influence of local causes of the epidemic, that I should still be unable to decide, without studying the question still further. I wouldn't stop with those facts alone.

Q. What local causes could create an epidemic of typhoid such as this in the city of St. Louis, as you know the physical conditions of the city?

3441 GENERAL CROW: Your question assumes the fact that he did not state as I understand him. Your question assumes that he stated that the local cause could create such an epidemic as you call it, in December, 1899. I didn't understand him to say that local causes would do that. He said that was one of the factors we might consider, as I understood him. I want to understand the matter as we go along, that's all.

MR. TODD: What local conditions would you want to know?

A. In deciding or endeavoring to find out the cause of the increase, which you assume to be considerable, and which I believe, if I remember correctly, was the case, I should wish to know among other things, if any changes had occurred in the water supply system of the city, compared with previous years, to naturally investigate questions concerning the milk and other foods, although the apparently high increase would hardly be due to such milk or food, though I do not say that it absolutely could not be.

Q. Assume in addition to that that the Health physician, or that the Board of Health were unable to discover any local conditions which accounted for that typhoid?

A. If we should wipe out the influence of foods or such
other local conditions as might cause it, and assuming that
3442 no local conditions did cause it, I think that I should nat-
urally infer that an epidemic was in some way due to an
infected condition of the water supply of the city, but how or
where that water supply became infected, I don't think I should
be able to say definitely from the conditions thus far assumed.

Q. Assume that no rational explanation has been able to be made for the cause of this epidemic in 1899, which is the more rational explanation for the subsequent epidemics of 1901 and 1902, the unknown cause that led to this epidemic or the opening of the drainage canal in 1900?

GENERAL CROW: I object for the reason that the record in this case does not disclose that there is no explanation offered for the increase in typhoid in this city in November, 1899 and December of the same year.

MR. TODD: I base it upon the testimony of Dr. Teichmann.

GENERAL CROW: That is not all the evidence in the case, however.

MR. TODD: I didn't hear Dr. Ravold make any explanation of that. He may have, but I didn't hear it.

A. I don't believe that it is possible to make a fair comparison between a cause which is unknown and which may perhaps have acted on one particular occasion, and as to which we do not know, whether it can or cannot occur again, 3443 with the Drainage Canal through which is delivered part of the sewage of the City of Chicago, as the cause of the increase in the number of deaths from typhoid fever in St. Louis, during the years 1900, 1901 and 1902, as compared with several years previous.

Q. You cannot state as an established fact that the opening of the canal at Lockport is the cause of the increase in typhoid in St. Louis, can you?

A. I cannot state it as an established fact absolutely, and conclusively proven.

Q. What effect does the sewage of Peoria have upon the water supply of St. Louis?

A. That would depend upon a considerable series of conditions.

Q. Well, assuming all the conditions you know to exist, can you give me an answer to the question without the assumptions?

A. Not without the assumptions, no sir.

Q. Do you know whether the sewage of Peoria purifies itself in 25 miles or 50?

A. I don't know that it does.

Q. Would you say that it did or did not?

GENERAL CROW: I object to the form of the question, for the reason that it assumes a fact not proven, or admitted; that is, that the sewage would have purified itself by the
3444 mere distance that it goes with water.

Q. Can you answer the question, Mr. Whipple?

A. Yes sir. Just read it again.

Q. (Question read).

A. If you mean by purification, the fact that the water into which the sewage of Peoria is discharged becomes free from all the constituents of that sewage; if you put the time within 25 or 50 miles, or if you mean that the water into which the sewage of Peoria is discharged—perhaps you will have to read that answer—

(Answer read) as follows: "If you mean by purification the fact that the water into which the sewage of Peoria is discharged, becomes free from all the constituents of that sewage,"

A. (Continuing) I should say that it did not.

Q. Would it purify itself by the time that it got to the St. Louis intake?

A. If you mean by purification of the sewage the fact that all of the elements of the sewage were absolutely removed from the water I should say that it did not, but in connection with both of these answers, I wish it to be understood that the factors of dilution, etc., must be taken into consideration.

Q. Is chlorine in water injurious to health?

A. No sir, not unless you get an excessive quantity of
3445 it, and it would probably be impossible to get enough to injure one as I understand your question.

Q. In order to make water dangerous to public health, there must be some pathogenic germ in it, must there not?

A. I should say it must contain something which would affect the human system, and that that something would ordinarily be a pathogenic germ, rather than any form of poison, or anything of that sort.

G. C. WHIPPLE.

ADJOURNED until 10:00 A. M., following morning, Saturday, May 16th, 1903.

Southern Hotel, St. Louis, Missouri.

3446 10:00 A. M., Saturday, May 16, 1903.

Parties met pursuant to adjournment, present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE,

Resumed the stand for cross-examination by Judge Johns, and testified as follows:

Q. In order to determine the general character of a water by microscopical examination, the samples taken and examined ought to be at different times and quite numerous, ought they not?

A. The more frequently the samples are taken, and the more samples that are taken, the more reliable would be our knowledge in regard to the character of the microscopic organisms present.

Q. They ought also to be taken at different seasons of the year, ought they not?

A. They ought if you desired to know the character of the water at different seasons of the year.

Q. To know the general character of the water for an entire year, samples should be taken frequently at different seasons of he year, should they not?

3447 A. If you wanted to know the character of the microscopic organisms in the water for the entire year and the changes which might take place in the number of microscopic organisms present at different seasons, the samples should be taken at different times of the year, and the more frequently hese samples were taken the better would be our general knowledge—the more reliable would be our knowledge in regard to the eneral character of the water with respect to microscopic oranisms.

Q. Take one set of samples in a cross section of the Illinois iver and examine them microscopically, you wouldn't learn nything except as to the condition of the river at that time?

A. Just read that question again.

Q. (Quesion read).

A. We would learn the condition of the water at the point where the samples were collected at that time.

Q. And that determination would not apply to the condition of the river, a month previous, or a month subsequent to those samples?

A. It might not.

Q. So that as to the condition of any of the water of any running stream, one set of samples taken at a selected time, would give no reliable information?

A. That would give reliable information as to the character of the water of that stream at that time.

Q. And at the very point where the samples were taken?

3448 A. At the point where the sample was taken.

Q. And at no other time, or at no other point?

A. No sir, so far as those samples alone, were concerned, and in the absence of any one from which we know that those waters remained constant in character through a period of time.

Q. In taking a sample of water as these have been taken in this case, all that the bottle contains is the water that comes in from its top at an aperture less than an inch in diameter?

A. Yes sir, I think the aperture was something approximately what you state.

Q. And there might be at a distance of two feet or any other distance in the water at the same instant, an entirely different condition of affairs?

A. Such a condition might exist, but it would not naturally exist in the water of the running stream where the water is reasonably well mixed up or in the water of the lake where the water is stirred up by winds, etc.

Q. Have you examined the data of the chemical and bacteriological examinations of samples of water of the Illinois River taken at Pekin Bridge, fourteen miles below Peoria?

A. Just read that again.

Q. (Question read).

3449 A. I have seen some analyses of that nature from samples collected at that point, yes.

Q. Did you notice the startling difference between the samples taken on the right bank and those on the left, as to the chemical and bacteriological elements?

A. I don't recollect at this moment.

Q. Samples are taken in a cross section of a river upon the theory that the average state of the entire number of samples is a correct representation of the condition of the river at that point at that time?

A. They are taken in a cross section in order that more reliable information could be had of the character of the water passing that cross section than could be obtained from a single sample,—

Q. And more reliable information as to the condition of the water at that point at that time?

A. At the point where the samples were taken at that time.

Q. Have you traveled up the Illinois river at all?

A. No sir.

Q. Did you make a physical examination—

A. No sir, excepting that I have seen the—no sir, using the word "Illinois River," I will say I have not.

Q. Have you traveled up the Mississippi river with a view of determining its physical surroundings and conditions?

A. No sir.

3450 Q. Nor up the Missouri river?

A. No sir.

Q. Or did you know about the character of the waters of any one of these streams, from such examinations as you have made of samples furnished you and from an examination of the tabulated results of examinations bacteriological and chemical, which have been shown you here, as introduced in this case?

A. Just read that question.

Q. (Question read).

A. I have seen the Mississippi river water between St. Louis and the Chain of Rocks and I know of the character of the water from examinations which I have made, and from the results of physical, chemical and bacteriological examinations which have been made by others, some of which have been submitted in evidence, and I have seen other published results of chemical and bacteriological analyses in the Illinois river, for instance, which so far as I know, may not have been presented here in evidence.

Q. And in making up an opinion as to the condition of these rivers, you have assumed that these results which you have seen as tabulated or published, were correct?

A. I was told that they were correct, yes sir.

Q. Is it a fact that if two chemists make an examination of waters from the same point, taken at the same time, they will differ in their results?

3451 A. That might happen.

Q. Does it not generally happen that they differ slightly?

A. As a rule they would differ slightly.

Q. Two chemists of equal experience, having equal opportunities for examination and material for examination will differ as to the results of the examination of the same water taken at the same point at the same time?

A. There might be differences within slight limits, yes sir.

Q. In the matter of nitrites for instance, a very slight difference might make a very material difference in a judgment as to the quality of the water?

A. No sir, I would not say that.

Q. What is the extreme limit for the potability of water so far as your information goes, as to the amount of nitrites in it, the water being considered independent of any physical surroundings?

A. I cannot express an opinion upon that point, as the term "potability" does not convey to my mind a well defined and definite meaning.

Q. There is no such thing as a well defined and definite standard for the potability of water, considered independently of its physical history, is there?

A. I do not consider that there is, because I do not con-
3452 sider that the term "potable" has a well defined and de-
finite meaning, and if that is the case we cannot have a definitely recognized standard regarding it.

Q. We have been going along here in ignorance, perhaps, on the assumption that potability meant a condition of water in which it was not deleterious to health to drink. Is there any such standard as that?

A. With regard to the presence of nitrites?

Q. Any chemical constituent?

A. I do not consider that there is a well defined standard regarding what I may term the safety of water with respect to its use for drinking purposes, excepting that of the absence of substances which might render the water unsafe.

Q. Do micro-organisms such as you have named in your testimony here, have any office in the purification of waters?

A. It is my opinion that it is a practically unknown subject as to whether or not the presence of microscopic organisms would render a water which once was unsafe, safer for use than if they were not present. It is my opinion that there may perhaps be some influences which certain microscopic organisms exert upon bacteria which might tend in that direction, but I do not believe that the information of that characer is very definite.

Q. So that the presence of a greater or less quantity of any kind of micro-organisms such as you have named, is not indicative that the water is undergoing a process of purification?
3453

A. I do not consider that it is indicative of that, no sir.

Q. Do you know whether the classes of micro-organisms which you have named,— diatomaceae, chlorophyceae and protozoa, have any separate or distinct offices in regard to the purification of water; that is to say, do the diatomaceae for instance, perform some office in the purification of water, different from that of the protozoa?

A. I do not believe that our knowledge on the subject is very definite, but it is conceivable that diatomes may exist with different relations to bacteria which may be present in the water than some of the protozoa, for instance, or some of the blue green algae.

Q. Have any of these classes of micro-organisms or the groups of micro-organisms, motility?

A. Some of them do have, yes sir.

Q. Which have?

A. I couldn't answer that by separating them into definite groups, and say that one group has while the other does not, because there are differences within the groups, but taking the proposition on an ordinary basis, the diatomes are not considered to be motile, the blue green algae are not considered to be motile, as a rule.

3454 Q. Do they belong to the diatomes?

A. No sir, they belong to the cyanophyceae. The chlorophyceae are, most of them, non-motile, while many of the protozoa are motile.

Q. Any one of these groups of micro-organisms might encounter such a condition of water as would exterminate them, might they not, from that water?

A. Any one of those groups might encounter conditions which might exterminate them so far as their life were concerned, but I have already testified that the cell walls of the diatomes are practically indestructible in water.

Q. Well, the organism lived inside of the cells, did it not? The life principle of that micro-organism is inside the cell?

A. The diatome is a plant, and the living matter of the plant lies to a considerable extent, I might say, practically within the cell wall.

Q. Well, it is open so that the water in which it lives or exists has an influence upon it?

A. There are believed to be openings between the exterior of the cell and the interior of the cell.

Q. Could a diatome then, thus fortified with a glass sell, be subjected to the influence of some water that would kill it?

A. I think that they can, so far as the life of the plant is concerned.

3455 Q. Now diatomes are found most generally in ponds and lakes?

A. The diatomes are found in all surface waters, to a more or less extent. There are certain diatomes which are found more generally in ponds and lakes, than in running streams, for example, except in so far as the waters of those streams are fed by the waters of ponds or lakes.

Q. The synedra are such diatomes as are found principally in ponds and lakes?

A. There are a great many kinds, a great many species of synedra.

Q. Well, the synedra pulchella, variety sub prolongata is found in ponds and lakes, is it not?

A. The synedra pulchella variety sub prolongata is more commonly found in ponds—in the waters of ponds and lakes than in the waters of streams, except is so far as those streams might be fed by lakes which contain them. I mean, the natural habitat of the organism is in ponds and lakes.

Q. Is that also true of tabellaria?

A. Yes sir, that is true of tabellaria. I will say, of some species of tabellaria.

Q. If the variety of synedra which you have mentioned, and the tabellaria could be required to pass through twenty miles of what has been called pure sewage, they would not be likely to survive the journey?

A. I think it might survive the journey, yes sir.

3456 Q. Have you any knowledge as to whether it actually will, from personal observations or experiments?

A. I have examined samples of sewage in other cities where I have found this organism and where, so far as could be told by looking at it through the microscope, the plant was in a living state.

Q. But that could not be determined with any certainity, I suppose, by microscopical examination?

A. I could not tell with certainty whether or not the organism—or the living princple of the plant was still alive.

Q. Did you ever examine any synedra or tabellaria that you knew to a reasonable certainty as a scientific man, had passed through ten miles of pure sewage?

A. I have examined samples of sewage in which I found these organisms, in the city of Boston,— the samples of sewage being taken from near the out-fall of the sewage, at Moon Island, and it is my impression that they must have traveled, I should say eight or ten miles at least, in the sewers of the city, but I cannot tell at the present moment just how far they did travel.

Q. Or whether they were dead or alive when you examined them—that the principle of life was in them?

A. To all appearances, as I examined them under the microscope they were alive, but I could not say definitely from that simple ocular inspection of them.

3457 Q. Assume that the Illinois river has upon both banks from Joliet to Grafton, or from La Salle to Grafton, large numbers of ponds and lakes, many of which are fed by springs, overflowing in time of high water, and acting as feeders to the Illinois river in time of low water, having their low water outlet into the Illinois river, could the synedra and the tabellaria, of which you speak, exist in such ponds and lakes?

A. Yes sir, they could exist there.

Q. Is there any geographical limitation to the existence of the synedra?

A. Do you mean with reference to latitude and longitude?

Q. Yes sir?

A. It is my opinion that these organisms are well distributed geographically.

Q. And that the State of Illinois is within their geographical distribution?

A. Oh, I should say that they might occur there, yes sir.

Q. Is that true also of the tabellaria?

A. Yes sir.

Q. Assuming that synedra and tabellaria of the kind you mention, exist in the waters of Lake Michigan, and also in lakes and ponds which are tributary to and discharge their waters into the Illinois River below Lockport, and these same organisms were found in the intake of the St. Louis waterworks,
3458 and that these organisms coming from Lake Michigan, have to pass through 24 miles of sewage of the drainage canal, being found in the St. Louis intake,—to which source would you prefer to attribute them?

A. In order to answer that question I should have to know the numbers of the organisms in Lake Michigan, as compared with the numbers assumed to exist in the assumed lakes along the Illniois river, and the relative volumes of water from Lake Michigan as compared with the volumes of water delivered from those so-called lakes.

Q. Assume that the number of synedra and tabellaria per cubic centimeter in the waters of Lake Michigan and the waters of the Illinois river lakes, and tributary streams were exactly equal; that in all physical respects the organisms from both sources had equal vitality, and started from their habitat on a journey to the St. Louis intake, and that the ones from lake Michigan had to pass through the drainage canal and they were found in the St. Louis intake, and eliminate all other considerations than these mentioned, to which source would you prefer to attribute them?

A. In order to answer I should have to know further the relative amounts of water coming from Lake Michigan and from the lakes and tributaries which you have assumed.

Q. Well, the relative amount of water now discharged
3459 from the Drainage Canal into the Illinois River, is greater
than is naturally in the Illinois River. Assuming that one more thing, which I concede to you, to which source would you prefer to attribute the tabellaria and the synedra in the St. Louis intake?

A. If we have a certain volume of water contributed by the tributaries of the Illinois river, and the assumed lakes which contain a certain number of these organisms, I will say, assumed to contain a certain number of these organisms, and if we have a greater volume of water from the Chicago Drainage Canal, which contains per cubic centimeter, as I understand it—

Q. Yes.

A.—an equal number of these organisms, then if we assume a thorough mixing of the waters, it would be my judgment that the organisms found in the resulting water would be more likely to come from lake Michigan than from the other sources named, and would be more likely to—in proportion to their volumes, and the volumes of the tributaries and lakes, as against the volume of the drainage canal, and I would like to explain it still further by saying that these organisms—that it would be my judgment that these organisms would come from both sources, but that more of them would come from the water which was greatest in volume, provided that the two waters contained an equal number per cubic centimeter.

Q. Then all other considerations being equal, you don't

3460 think that the fact that the supposed organisms traveled through 22 or 24 miles of sewage, of any consequence?

A. Practically not in this case, or in the case of these two organisms so far as they refer to any examinations that have been made, for the reason that in the examinations which I have made, I have not attempted to differentiate between a live synedra and a synedra not capable of developing.

Q. The synedra are not naturally and orginally inhabitants of running streams, are they?

A. You refer to this particular variety?

Q. Yes, the kind you mentioned?

A. The synedra pulchella variety sub prolongata, are not, so far as my experience has shown, naturally found in the waters of running streams except in so far as these streams are fed by ponds or lakes.

Q. But if they are found in the waters of running streams, they are fed by ponds and lakes, you attribute their origin to the ponds and lakes, do you not?

A. From my experience, that would be the most probable origin in those cases.

Q. So that when these organisms get into a running stream, polluted with sewage, they are out of their natural element?

A. They are out of the habitat in which they are most likely to develop.

3461 Q. Now take any volume or number you please of the variety of synedra of which you have spoken, and start them toward a given point 150 miles distant, in an element in which they do not originate, and in which they are not likely to develop; start an equal number in equal condition, with like history, 60 miles from the same destination, which ones would you prefer to say would arrive at the given point, traveling in the same media and in the same direction?

A. I don't think I fully understand your assumption; but if you mean that we have a stream of water flowing from say the point A to the point C, and if there was no change in the volume of that stream of water as it flows from the point A to the point C, and if we consider a certain number of these organisms at the point A and let them travel to the point C, and we start an equal number at a point B, below the point A and t them travel to the point C, it is my opinion that all of the rganisms would reach the point C, except in so far as they ight be broken up in transit, or might settle out on the way.

I have stated that in the microscopical examinations which have made, I have not taken into account the actual life of e synedra and tabellaria present; I have simply ascertained e number of the cells of the organisms regardless of whether they were—you may say dead or alive.

462 Q. Which ones would be most likely to arrive at the given point alive in the case supposed?

A. That would depend upon the character of the water and pon the conditions which affect the life and death of this or- anism, which conditions I do not believe it is possible to de- ne definitely in the present state of our knowledge.

Q. Take an equal number of synedra of the kind you have entioned, at two different points, traveling in precisely the me amount of water, at the same time, one point 150 miles rom the destination, another point 60 miles from the destina- on, the water in which they are traveling not being the kind of ater in which they originated, which set of synedra would be ost likely to arrive at the destination alive?

A. Just read that question.

Q. (Question read)?

A. So far as their arriving alive is concerned, I am unable state from anything mentioned in the assumptions, and from ck of better knowledge on the subject of the life and death of e organisms, and as to the numbers which might arrive from e one place or the other, that would depend, among other hings, on the amount of sedimentation between the first and the econd places, and the point of destination.

3463 Q. Eliminating all considerations except those embraced in the preceding question, and considering only the relative distances which the two sets of organisms traveled, do you or do you not know which would be most likely to rrive at the destination?

A. I don't think it can be stated without further assump- ions than those that you have made, as there are so many fac- ors which have to enter the problem.

Q. I have a right to state conditions to you as an expe and I state only such conditions as are in the second precedi question, and upon these assumptions, do you or do you n know which ones would arrive at the destination?

A. Will you please state the conditions again?

ATTORNEY GENERAL CROW: Allow me to suggest th you have the right to answer the question in your own way. you cannot answer it, as he puts it, just say so.

JUDGE JOHNS: And you can make any answer you plea

A. Please state the conditions again; perhaps I did n understand them all.

(Question read).

A. Well, I cannot answer your question without maki further assumptions in regard to the conditions.

Q. The question requires you to answer without regard any other assumptions?

A. Well then, without regard to any other assumptions cannot answer your question.

Q. Do you think then that the distance traveled by syned
of the kind you have mentioned, in water in which th
3464 do not originate, and which is not favorable to their d
velopment, makes no difference in the probability of th
arriving at a given point?

A. So far as distance alone is concerned, and disregardi absolutely everything else, I don't think it would make mu difference whether they started ten miles from a certain pla or twenty miles from a certain place, but of course there wou be conditions which would naturally exist, which would te to influence their arrival.

Q. Are you familiar with the bacillus prodigiosus?

A. Yes sir.

Q. How many varieties of bacillus prodigiosus are ther

A. I could not say.

Q. Do you know whether there are three, four or five?

A. I have examined several different cultures of bacill prodigiosus, which, while they agreed in their main points resemblance, had slight differences from each other in cultur in the laboratory, but to what extent these differences were d their being different varities, or different kinds, I am not ble to state.

Q. Do you believe that 100,000 million of bacillus prodigious could be concentrated in one cubic centimeter of water and ve?

A. I believe that they can be concentrated into such a volume of water, but to what extent they would live there,
465 I don't know.

Q. Do you think that one thousand million bacillus proigiosus by special culture, could be concentrated in one cubic entimeter of water and exist for two days alive?

A. I don't know.

Q. A bacillus may be transported by any means in which here is water involved, may it not, from one point to another?

A. A bacillus may be carried by water from one point to he other provided nothing happens to it on the passage.

Q. It might be taken from the river by pump and thrown long the decks of a steamer traveling up the river, in the prosss of washing the decks, and go out in the river five or ten miles bove where it was taken from, might it not?

A. I supose it might.

Q. Any bacillus existing in water might be taken up stream y boats or aquatic animals or in any way in which water was ansported, above where it was taken out of the stream might not?

A. You mean that a bacillus might be taken in a portion f water and put into a boat and carried up stream?

Q. Yes?

A. And then put down in the water again?

Q. Yes?

A. If conditions were favorable, yes sir.

466 Q. They might be taken from one point in the water by acquatic animals,—ducks, geese, or any acquatic animal, nd transported up the stream a very considerable distance, ight they not?

MR. JEFFRIES: What bacillus are you talking about ow?

JUDGE JOHNS: I am talking about bacilli in general.

A. I think that a bacillus, speaking in general, as I unde stand your question, might under certain conditions, becon attached to a duck for example, and if the duck might trav up stream the baellus might get away from the duck and into the water, yes sir.

Q. Yes,—it might be taken up in a duck or through a pum and travel up stream and be used for the purpose of washing th decks of a boat, and returned to the water again alive, three four miles or ten miles from where it was taken out?

A. I think it might, yes sir.

Q. That principle would apply as well to Prodigiosus well as to any other bacillus would it?

A. So far as my knowledge goes, yes.

Q. Then the fact that the baellus prodigiosus, one colo of them, was found three miles up stream from the place which it was put into the river, wouldn't have any very spec significance?

A. Significance as to what?

Q. As to the fact as to whether it was naturally an inhab tant of that river?

3467 A. If we—perhaps you had better read that again,

Q. (Question read).

A. So far as that fact alone is concerned, it would simp show that the water at that point at that time contained th bacillus.

Q. Assume that the bacillus prodogiosus could not of its go up stream, and that it was put in a stream at a certain poi and was not naturally an inhabitant of that water, and that it w found three miles above the place where it was put in, would be possible, by any of the means mentioned in the previous qu tions, to transport it thus far by the stream?

A. I didn't get all of that; please read that question.

Q. (Question read).

A. Do you mean would it be possible to have the bacil transported up stream, by boat, for example?

Q. Yes, or ducks, or any other thing by which the wat of the river in the place where the bacillus was put into t water was removed up stream and deposited again in the strea

A. If I understand your question correctly, it is my opinion that if a bacillus were taken out from the place where it was put in and carried up by a boat three miles, and then put into the water—

MR. WOERNER: It would be there?

A. It would be there.

3468 JUDGE JOHNS: Would there be any reason why it might not as well be there under those circumstances, as inherent to the organism itself, that is to say, is it of such a character that it would not bear such transportation?

A. I think it would bear the transportation probably—perhaps you had better read the first part of that question again.

Q. (Question and answer read).

A. Under the circumstances which you have mentioned.

Q. Do the bacilli which are found in running waters, and are afterwards in the course of experiments, put into bottles of sterilized water and hung out in the sun, live as long as they would in the natural condition of the water in which they existed?

A. Will you read that question again?

Q. (Question read).

A. I have no definite means of knowing.

Q. You have no opinion on that subject?

A. I have no definite opinion, as it would depend upon very many conditions, and the effect of these different conditions being, I may say, comparatively unknown.

Q. Suppose bacilli, naturally inhabitants of running waters which are turbid to some extent, should be removed from their natural place of abode, developed by special culture, put in bottles of sterilized water, and hung out in the sun, would
3469 that be a fair means of determining how long they live
in their natural waters?

A. I dont' think it would enable us to tell how long they would live in their natural waters, no sir.

Q. Such an experiment would only prove how long they did live under the circumstances in which they were experimented upon?

A. Yes, just the results would be available in so far as—

Q. So that an experiment of that kind proves nothing as to the life of any particular bacillus in its natural situation?

A. It does not enable us to give a definite opinion as to that point.

Q. If the bacillus prodigiosus under special culture was used in such experiments in sterilized water, in a bottle, in the city of St. Louis, and exposed to the sun for any number of hours, each one of the succeeding days, and lived fifteen days, you could not determine from that how long it would live in its natural waters, undisturbed?

A. Not from that alone, but of course balancing up the conditions as well as possible, conditions in the laboratory experiment, if I may call it that, with the conditions in nature, it might enable us to form—it might guide us in our opinion as to how long it would live in nature, but it could not definitely determine that.

Q. The conditions of the laboratory experiment in which
3470 the bacillus is produced by artificial culture, and exposed
to the sun in a bottle, in water to which it is in nature totally unaccustomed, could not very well be balanced with the natural conditions, could it?

A. It could not be balanced so as to obtain a definite result no sir.

Q. Now if the bacillus prodigosus, as many as could be contained, of specially prepared culture, were put into a forty gallon wiskey barrel, first throughly sterilized, and dumped into the Illinois river at or near its mouth, in August, 1900, do you know whether that bacillus thus introduced into that water would live continuously and become native to that water?

A. It is my opinion from what I know of the nature of the bacillus prodigiosus, that it would in all probability live in continually decreasing numbers, in the water in which it was placed, but just how rapidly the numbers would decrease I don't know. or just how long it would live, I don't know.

Q. Now if the bacillus prodigiosus was afterwards, in quantities of 107 barrels of water, containing 1,000 million to the cubic centimeter, were afterwards in November of the succeeding year, put into the waters of the Illinois drainage canal, 357

or 360 miles from St. Louis and 23 days afterwards, one of them was found in the tap at the City Chemist's office
3471 in St. Louis, would you know to which plant of bacillus prodigiosus to attribute that colony which was found—just read that question again.

Q. (Question read).

A. That would depend upon the number of factors—

Q. Assume that bacillus prodigiosus were put into the waters of the Illinois river in August, 1900, one barrel of them, and afterwards—

A. What point in the Illinois river do you mean?

Q. At or near its mouth, or in the Mississippi river at or near the mouth of the Illinois river, and that in November of the succeeding year 107 barrels of it containing 1,000 million of these organisms to the cubic centimeter were put into the drainage canal at or near Lockport, and afterwards a colony of this bacillus was found in the intake of the St. Louis Waterworks and another at some other point in the city, of St. Louis, to which colony of the bacillus thus planted, eliminating all other considerations whatever, would you attribute the ones found at the intake and in the water taps of the city of St. Louis?

A. The question cannot be answered without taking into consideration other considerations, other facts. I should naturally assume, or I think it would be more reasonable to expect that it came from the second dose, if I may use that ex-
3472 pression, than from the first, but this would involve questions in regard to the life of the bacillus, the flow of the streams, sedimentation and such factors.

Q. Taking into consideration all that you know of the physical conditions, and the surroundings of the Illinois Drainage Canal and the Illinois river and the character of the bacillus, and the Mississippi river and the intake, and the location of St. Louis on the Mississippi river, and assume that some bacillus were put in near the mouth of the Illinois river in August, 1900, and in November, 1901, 107 barrels of them were put in near Lockport in the drainage canal, and that they were afterwards found at the intake and in taps of the City Waterworks, here, could you tell with any kind of certainity to which dose of the bacillus put in these waters, those found were to be attributed?

A. It is my judgment that if those found came from either one dose or the other, that they came from the second dose rather than from the first.

Q. Could you tell it with any kind of certainty?

A. I think with reasonable certainty, yes sir.

Q. Notwithstanding that one traveled 350 odd miles and the other was placed in the water at a distance of less than forty miles from the intake?

A. Yes, I think so still.

3473 Q. Is that reduced to a moral certainty in your mind?

A. Yes sir.

Q. Why?

A. It is my opinion that between August, 1900, and November, 1901, if I have the dates correct, that all of the water in the stream of the Illinois river and the Mississippi river between the points where the first dose was added and the intake of the St. Louis waterworks, would have passed down stream, and it is my opinion that many of the prodigiosus would have died out in that time by natural decrease in the water, and I don't believe that even that interval—well, just stop right there, that is enough.

3474 Q. That is a matter of opinion, not a matter of actual knowledge from any experiments or in any way in which that fact could be ascertained?

A. It is a matter of opinion. It is based upon facts which are shown to be reliable and sufficient to enable me to take that position.

Q. There is no way known to the science of chemistry and bacteriology or microscopy, by which the fact could be certainly ascertained, is there?

A. Perhaps not to a mathematical certainty, but I believe it to be established beyond a reasonable doubt.

Q. As a matter of inference from given facts?

A. As a matter of judgment from facts I believe to be reliable.

Q. Now the mixing of waters of two rivers must depen upon circumstances or volume, and of the relative height of the two rivers at the moment of mixing?

A. These factors enter into the question of mixing, yes sir.

Q. The waters of the Missouri and Mississippi river for instance, do not at all times and at all seasons of the year mix equally?

A. At what point?

Q. At any given point equally with other seasons of the year and other stages of the river.

GENERAL CROW: You mean by the last phrase, other seasons of the year. 3475

JUDGE JOHNS: It is supposed that forty-five miles below the mouth of the Missouri there was a certain per cent of the Missouri river water determined by algebra, and a certain per cent of the Mississippi river water found in the waters at that point, in March. Would that be any indication of the per cent of the same water at the same point, in September?

GENERAL CROW: Of the same year?

JUDGE JOHNS: Of the same year?

A. If you consider the question of percentage mixture I would say that the percentage of mixture of the two waters would not be the same at all times.

Q. If the Mississippi river by gauge readings immediately above its confluence with the Missouri were five feet below a gauge similarly placed in the Missouri river, the waters of the Missouri and Mississippi would mix more rapidly below the confluence of the two than if they were at an equal gauge, would they not?

A. I cannot answer that without considering some particular point at which you wish to consider the mixture.

Q. Well, take it at the chain of rocks?

A. Well, if you consider the water at the chain of rocks, I should say that the water of the Mississippi river would not be as well represented there as the water of the Missouri river relative to other times when the gauge reading of 3476 the Missouri river was equal to that of the Mississippi river, assuming that the volume of the stream varied substantially as the gauge reading.

Q. Well, as a matter of fact the mixing of the waters of the——the percentage of the waters of the two rivers are not the same at any one point, at any given point, are they?

A. You do not mean at any one time, you mean at all times?

Q. Yes sir.

A. As a rule, if we consider a certain point, below the point of mixture, they would not be the same at all times, on account of natural variations in the flows of the two streams, and questions concerning their currents, etc.

Q. So that when it is determined that upon a certain day the percentage of Mississippi river water and the percentage of Missouri river water, bear certain relative proportions to each other, that determination would not apply to any certainity, with any other day or with any other time, would it?

A. It would not necessarily apply to any time, no sir; it would simply apply to that one time.

Q. Now you have testified here to volumes of water, to percentages of volume of water of the Missouri river and the Mississippi river at the intake, based upon total solids?

3477 A. Yes sir.

Q. And also upon the chlorine as to the Illinois and the Mississippi?

A. Yes sir.

Q. Do you mean to say from the total solids and the percentage of total solids entering the intake upon the day upon which you made the calculations, that the percentage of actual water was the same, or do you simply mean to say that the percentage of water carried a certain percentage of the solids in solution?

A. Carried a certain percentage of the solids in solution and to represent relatively the volumes of the water as far as the solids represented the samples.

Q. So that when you say of the Illinois river and the Mississippi river for instance, that there was a certain per cent of the volume of water at the Mississippi river below the Illinois based on a consideration of chlorine, you simply meant to say that in the waters of the two rivers considering that the chlorines remained constant, the chlorines in the mixed water represented a certain per cent of the chlorine in the Illinois and the chlorine in the Mississippi?

A. Yes, and to the extent which the samples represented, you may calculate the percentages of the two river waters.

Q. As to the volumes of the two waters?

A. So far as the samples are representative.

3478 Q. The question is, are the samples representative of anything more than a percentage of the mixture of chlorine, for instance?

A. I think if the determinations for the chlorine represent fairly the waters from which the samples are taken, that the calculation will give us the limits of accuracy governed by the sample and the determinations of percentages of the two waters.

Q. Suppose that the chlorines in the Illinois River at Grafton were 24 parts per million and that the chlorine in the Mississippi upon the same day above Grafton, were 4 parts per million; what would be the per cent of the chlorine, if the two waters mixed?

A. I couldn't tell without knowing the relative volumes of the two waters.

Q. In any determinations which you have made of the percentages of water entering the intake, based upon solids as to the Mississippi and the Missouri, or upon the chlorines as to the Mississippi and the Illinois, did you take into consideration the relative volumes of the waters of the two streams?

A. That practically is taken into consideration in the formulae used in obtaining that. We would take it into consideration absolutely, but relatively in one case we say that the volume
of the water is X, an unknown quantity—I will not say
3479 an unknown quantity, but an unknown percentage of
water, and in the other case, it is 100 minus X for the
Illinois, so to that extent we take into consideration the volume.

Q. Well, that is the theoretical volume. When you made a determination there, based upon the chlorine of the waters of the Illinois and the Mississippi, what were the relative percentages?

A. Do you want me to read them absolutely?

Q. Yes, if you please?

A. I made these calculations at five points in the cross-section of the Mississippi river at Alton, which were lettered from A to E, beginning from the Missouri shore and running towards the Illinois shore, and I found that the per centage of Illinois river water varied from 7.8 per cent at point A, to 37.2 per cent at point E.

Q. Now as to the Mississippi?

A. And that the percentages of the Mississipi river water at the same points varied from 92.2 to 62.8 from the point A to the point E.

Q. In the Mississippi?

A. In the Mississippi river at the cross section at Alton.

Q. Well, what per cent of Illinois river water and Mississippi river water mixed, did you conclude existed at the point taken for calculating the per cent?

3480 A. Do you mean what per cent mixed throughout the entire cross-section?

Q. Yes, below the confluence of the two rivers. If I understand you, in order to arrive at a determination of the percentage of the waters of the two rivers, you considered the chlorine at the cross section at Alton and consider the chlorine at the cross section at Grafton?

A. Yes sir.

Q. And then did you not also consider the percentage of the waters mixed at some point still further below?

A. I also found the percentages at which they were supposed to be mixed at Hartford on the Mississippi river.

Q. Now when you got through with that determination, what was the relative per cent of the waters of the Illinois and Mississippi based upon the chlorine as the basis of calculation in the mixed waters?

A. Do I understand you to mean considering all the samples in one cross-section and all the other samples in the other cross section and then considering them as a whole, then to find the percentage of Illinois river water which might exist at any point?

Q. Below, yes.

A. Well I made a calculation similar to this. The cross

section included 5 points in the stream, one point taken in
3481 the middle of the stream, which was called point C, two
points taken, near the edges of the stream, which were points A and E, and two points taken intermediate between the center and the extreme, which were points B and D. I do not recall exactly the cross section of the river at this point, but for the sake of making an approximate comparison, I assume, if you wish to obtain an average of the percentage of Illinois river water at that cross-section, that the points at the sides of the stream should be given only half way, half of the way to those intermediate, of the intermediate points, inasmuch as the intermediate points may be considered to represent a greater width of the stream than the side points. I believe in the absence of information as to the cross section, that that is a fair assumption upon which to work and make an average with such allownace, and I found that the per cent which the Illinois river, which the water of the Illinois river would be of all the water in the stream at that point, was 19 per cent, while making a similar calculation from the figures obtained at Hartford, I found that it was 19.7 per cent which was a practical check, the one upon the other, within what I believe to be the limits of accuracy of the determination in samples.

Q. In speaking in round numbers the Illinois river was as to its waters, to the Mississippi river as to its waters, as 20 to 80, or as twenty parts in a hundred.

3482 A. Speaking in approximate terms, such was found to be the case from these calculations.

GENERAL CROW: At what time was that?

A. This was in the month of November, practically the month of November, 1901.

Q. That was low water stage.

(No answer.)

JUDGE JOHNS: Do you mean to say that at that time the percentage of actual water contributed by the Illinois river and the Mississippi river to the actual water of Hartford, was 20 and 80 parts respectively in a hundred?

A. That was what was shown by those figures and I compared those figures with certain data which I obtained from the river stages at that time, and I believe these figures to be approximately near the truth. I haven't the data to make an exact comparison, but I believe they were within reasonable bounds.

Q. I don't want you to be accurate, but do you mean to say that those figures thus obtained, approximately, substantially represent the actual amounts of the waters of the two rivers at Hartford at that time, or do you mean to say that they represent practically the amounts of chlorine in the two waters, contributed to that point?

A. I mean practically the amounts of the water of the river.

3483 Q. The actual water in volume?

A. Yes, substantially.

ADJOURNED until 2:00 p. m. same day, May 16, 1903.

3484 Southern Hotel, St. Louis, Missouri. 2:00 p. m., Saturday, May 16th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE

resumed the stand for cross-examination by Judge Springer, and testified as follows:

Q. Mr. Whipple, what importance do you attach to the numerical results of a single bacteriological examination of a sample of water in so far as it may be important in considering the sanitary conditions of the water?

A. That would depend in part upon the result obtained. If the number of bacteria found was extremely low, it might indicate a comparatively good sanitary condition; if they were extremely high, it might indicate a comparatively bad sanitary condition. If they were intermediate, between what may be called very high or very low, I would not be able to draw any conclusion from that alone.

Q. In order to reach a correct conclusion as to the sanitary condition of a given water, it would not be necessary to obtain

the number of samples, or to make a number of examina-
3485 tions of those samples, both bacteriologically and chemically?

A. The larger the number of samples and the more complete the examination made, the more—the better judgment we could make of the sanitary condition of the water or the sample analyzed.

Q. Can microscopical examinations of water be depended upon to determine the pathogenic qualities of drinking water?

A. No sir.

Q. Are the common microscopical organisms found in water the cause of disease?

A. They are not so far as I know.

Q. Does their presence indicate pollution?

A. Not definitely, but as I have already testified, there are certain forms of microscopic organisms which are so commonly found in waters known to be polluted, that to some extent their presence in water is indicative of pollution.

Q. To what extent?

A. To a slight extent.

Q. To a slight extent?

A. Well, I may add to a very slight extent.

Q. Where the chemical examination of water may determine the amount of organic matter contained in a sample, does it determine the nature of the water?

A. It does not definitely determine the nature of the or-
3486 ganic matter in the water.

Q. It does not?

A. No sir, not definitely.

Q. Are not microscopic organisms very susceptible to changed conditions of temperature, pressure and of light?

A. Some of them are, yes sir.

Q. What ones?

A. Well, if you take for example the microscopic organism known as uroglena. If that organism is subjected to unusual pressure, as it sometimes is, in the water pipes of a distribution system, that micro-organism may be broken up. I have seen some organisms go to pieces apparently under the influence of sunlight and if we take some of the delicate forms of microscopic organisms they will go to pieces under the influence of high temperature, for example.

Q. Is that all?

A. I think I have answered the whole question.

Q. Well, I asked you if you were through?

A. I think so.

Q. In order that an analysis or a bacterial examination of a given sample of water should be of real value, ought not the analysis or examination be made at the time the sample is taken from the water?

A. In order to obtain the most accurate result, the bac-
3487 teriological examination of the sample should be begun
at the time, or I may say, immediately after the time
when the sample is collected, but the character of the water
would, to a considerable extent, influence this fact. Waters of
some character could be allowed to stand longer than others
without having the result of the bacteriological examination interfered with by standing.

Q. What would be the character of the water to which you desire to direct attention that would influence the result?

A. I simply mean this: that if you have a water which contains comparatively little food upon which the bacteria might thrive, such for example as we might have in well water, that water might be allowed to stand longer before the bacteriological examination was made, than say a water which was rich in organic matter, without having the result of the bacteriological examination seriously interfered with.

Q. Assuming that the water to be analyzed or examined came from the Illinois river during the months of October and November, what would you say as to the time that water should be examined after taken from the stream?

A. I should say that such water as you mention should be examined immediately after the sample was collected, or within a few hours of the time of its collection. I don't think I could give you a maximum limit beyond which the results would be absolutely worthless.

3488 Q. What was the time which elapsed between the time of the taking of the samples of water to which you have referred and of which you made microscopic examinations, and the time which you made those examinations in New York?

A. If my recollection serves me correctly it was about three days in some cases and about four days in others, and if I am not mistaken, four days was the longest time that elapsed between the time of collection marked on the tag, and the time when I made the examination. I can look this matter up; I can go into it further—

Q. That is sufficiently accurate for my purpose. Is it your opinion that that time was not too great to affect the results which you found by your examinations?

A. It might affect certain results which I found; it probably would not affect others.

Q. What results would it affect?

A. It might affect for example certain of the protozoa which might develop in the sample between the time of collection and the time when the examination was made. It also might affect such organisms as some of the blue green algae, which might conceivably disintegrate between the time the sample was collected and the time the examination was made.

Q. Would it affect your determinations in any other way?

A. Well, there are other microscopic organisms which 3489 were present, such for example as the diatomes, where of course I did not make a distinction between living forms and the cells which might contain matter not in a living stage and because the conditions surrounding the samples between the time when they were collected and when they were examined would probably not admit of the growth of these diatomes, nor would they admit of the—or be likely to admit of the destruction of these cells which have silicious walls. I do not believe that the results regarding those organisms would be interfered with by the standing of the sample, or by the lapse of this time.

Q. Were those samples received in ice or in the natural conditions in which they were collected?

A. They were not received in ice.

Q. Would not the shaking of the bottle incident to railway travel, tend to the breaking up of the organisms?

A. It might tend to break up some of the more delicate forms; it would not tend to break up the cell walls of the diatomes.

Q. Is it your opinion that substantially the same results would have been obtained from those samples of water, if you had examined them immediately upon their being taken from the water, that you did obtain by the examinations made four days afterwards?

A. I would say "Yes," so far as the diatomes are concerned, but perhaps not so far as some of the more delicate forms are concerned. 3490

Q. What would be the more delicate forms?

A. Well, some of the protozoa, such for example as dinyobryon and some of the blue green algae, as for example anabena.

Q. What would have been the probable difference, and what would it have indicated from a scientific standpoint?

A. In the case of the anabena it is possible that while not necessarily probable, that if this organism had been present in the sample when collected, it would show smaller numbers after standing for a number of days, while in the case of the protozoa in monas, it is quite possible and perhaps probable that the sample originally collected might show fewer organisms in number than after standing.

Q. Would this change the result of your determinations materially?

A. That would depend from what standpoint we judged the determinations. If you mean from strictly a sanitary standpoint I should say that it would not, because, as I have said these microscopic organisms are not a definite indication of the sanitary quality of the water.

Q. Did you test any of those waters for the purpose of determining the presense of pathogenic germs?

A. No sir.

3491 Q. In your examination of the bottles from the rivers to which our attention has been called in this investigation and Lake Michigan, you stated that there were two microscopic organisms which you discovered in Lake Michigan, which you did not find in the waters of the Mississippi and the Missouri Rivers. Do you mean to have us infer that those genera were not present in those waters?

A. In the first place I did not make a statement exactly as you have told it. I think that I stated that there were two organisms which I called synedra pulchella variety sub prolongata, and tabellaria, which were especially characteristic of those two waters, but I think I stated that only with regard to the synedra pulchella variety sub prolongata, that that organism was not found anywhere else than in the water of Lake Michigan, or the waters with which lake Michigan might have been afterwards mixed.

Q. Do you mean by that that that variety of micro-organism was not found by you or has not been found by other experts other than in Lake Michigan?

A. It was not found by me in waters other than those of lake Michigan, and the waters with which Lake Michigan water might become mixed, nor so far as I know has it been found by other experts in the other waters mentioned.

Q. Are not the microscopic organisms which you found in lake Michigan, found in all parts of the world, and under 3492 a great variety of climatic conditions?

A. I believe they are, speaking generally.

Q. These organisms have received I believe I understood you to say, a vast amount of investigation by scientists?

A. I think they have received a great deal of attention.

Q. Are the laws governing their distribution in determining the places at which they may be found, understood at this time by scientists?

A. They are certainly not fully understood. I think we are beginning to understand something concerning these laws.

Q. May not a certain genus of the varieties to which you have referred, grow vigorously in one pond or place, and be absent from a neighboring pond where the conditions are equally as favorable for its existence?

A. Yes, so far as we know those conditions, I can recall such cases.

Q. Does it not often happen that a certain genus of the species to which you have referred may suddenly appear in a pond, lake or water in which it has never been before seen?

A. They certainly do suddenly appear in waters where apparently they have not before been seen, but just how far back observation has extended in regard to the previous history of that water, or just how far observations of a scientific
character have been made concerning that water,
3493 would have to be taken into account in comparing their
presence today with their presence of former days.

Q. Might not an examination of a sample of water in the Missouri river or in the Mississippi river above Grafton taken today, show the presence of the two genera which you failed to find in the samples found in Lake Michigan?

A. Well I didn't catch that.

Q. (Question read).

A. They might.

Q. I believe you stated that there were only three places at which samples of water were taken which were forwarded to you for examination at the mouth of the Missouri river, is that correct?

A. I stated that there were three samples sent to me from the mouth of the Missouri river, collected in a cross section by Professor Van Ornum. These were sent to me for examination but I did not make a microscopical examination of them; I simply determined the turbidity of those three samples.

Q. And from what examinations did you ascertain that there were no genera of the two species to which we have referred, found?

A. From the microscopical examinations of samples which were sent to me during the months of October and November, 1901.

Q. How many of such samples did you receive?

3494 A. I should have to look at that sheet in order to refresh my memory. (After referring to chart) I received five samples which I analyzed, but I might add that I received two broken bottles marked as having contained samples from the Missouri River. As the bottles were broken when I received them of course they contained no water.

Q. Did you ascertain from the five samples that you examined where and when they were taken?

A. The tags which were attached to the bottles stated that the samples were collected from the Missouri river at Fort Bellefontaine, and the dates of the samples were given. Shall I read the dates?

Q. Yes, read the dates?

A. They were collected respectively on October 16th, November 1st and November 13th, November 14th and November 21st, 1901.

Q. Well, when were the other samples taken from the water, about which you have testified, in Chicago,—those taken in Chicago, the Lake Michigan water only?

A. The samples which were collected from Lake Michigan were collected between November 4th and November 29th, 1901 I think it is, I can hardly read these figures.

Q. Have you the dates at which they were collected. You say between November 4th and November 29th?

A. Yes, I have them all here.

Q. Let me have them please. November 4th was the first.

3495 A. There were two samples collected from the Lake View crib on November 4th,

1 sample from Carter Harrison crib on November 6th,
1 sample from the Carter Harrison crib on November 8,
1 sample from the Lake View crib on November 13th,
1 from the Carter Harrison crib on November 15th,
1 from the Four-Mile crib on November 20th,
1 from the Lake View crib on November 22nd,
1 from the Four Mile crib on November 27th,
1 from the Lake view crib on November 29th.

Q. Why were these samples taken in October and Nomember.

A. Which samples do you mean?

Q. That you have examined?

A. All of them?

Q. Well those to which you have just referred. I believe they were all taken in October and November, were they not?

A. All the samples which I examined microscopically were collected I think in October and November. I will read the entire list right through, if you wish.

Q. No, I don't want any more. But I ask why your examinations were confined to those two months?

A. Why were they?

Q. Yes?

A. I simply examined the samples that were sent to me;
3496 I can't tell why the samples were collected in October and
November rather than at any other time.

Q. You were certainly not asked to examine any other than these?

A. I simply examined the samples that were sent to me to be examined.

Q. Do you know of any special reason why the samples which you examined should have been sent from those months, rather than from other months?

A. I do not; I know at that time that they were making a general investigation of the waters; I don't know why they were made during those two months rather than at any other time.

Q. If additional samples of water have been taken at other times during the year 1901 and examined microscopically, to ascertain the presence of the micro organisms to which you have referred, is it not probable that those other samples of water would have disclosed—taken at Bellefontaine or in the Mississippi river above Grafton, would have disclosed the presence of the two genera which you stated were not found at those places?

A. I can't say that it is probable that they would, but they certainly might have disclosed it.

Q. They might have done so?

A. Might have done so, yes sir.

3497 Q. In your examination day before yesterday I believe
it was you cited two instances in which typhoid fever
germs had existed for ten days previous to their introduction to the water supply from which an epidemic had originated. Will you please state the distances which were traveled by the germs before they reached the water supplies which they entered?

A. I can't tell you exactly, but in the case of Lawrence, which I mentioned, it was supposed that the typhoid bacilli traveled from Lowell down the Merrimac River; thence into the water supply system and through the reservior into the—perhaps I had better say through the reservior into the water supply system a distance which was somewhere near 20 miles, I can't say exactly. I have frequently covered the distance. I am speaking quite from recollection.

Q. And in the other case?

A. The other case was that of Detroit, where, if my recollection serves me, the distance traveled was some fifty or sixty miles,—again speaking from recollection.

Q. Is there any other recorded instance in the books where the typhoid fever germs that were supposed to have produced an epidemic were carried a geater distance by water than those were carried in the Detroit case?

A. I think I have heard of greater distances, but I am unable to rêcall at the present moment. I mentioned the distance of fifty or sixty miles the other day because I felt quite 3498 sure that it had been carried at least that. I think it has been carried a greater distance, but I am less confident of the greater distance.

Q. Would not the fact of the distance traveled, or to be traveled by pathogenic germs, such for instance as typhoid fever germs, be a material and important factor in determining the presence of these germs at a point remote from their introduction into the water?

A. I think it would be an important factor in so far as it affected the time required for the bacilli to travel through water from a point where they might be introduced, to another point below; I don't think it is any question of linear distance, so much as it is time of transit.

Q. Are there no other elements to be considered than the time of transit?

A. Indeed there are.

Q. What are those elements?

A. There are a great many elements to be considered.

Q. Name some, will you please?

A. For example, the so-called vitality of the organisms, the rate at which they die out in water; the rapidity of the current in which they flow; with reference to possible sedimentation; the possible phenomena that they might settle to the bottom of the stream and again be taken from the bottom of the

stream and carried down; the question of the tempera-
3499 ture of the water might influence their vitality; the character of the water might to some extent. Those are some of the elements which would enter into the question.

Q. Has the fact been determined among scientists as to whether pathogenic germs multiply in water?

A. I cannot say that the fact has been absolutely determined, but I think it is the concensus of the opinion of scientists that such a pathogenic germ as typhoid fever for example, does not develop in water, but on the contrary, dies out. Perhaps I had better say, continues to live in water in constantly decreasing numbers, but—well, I think that is enough.

Q. If the pathogenic germs, such as typhoid fever germs for instance, multiply in water the same as the ordinary water bacteria, would it not soon happen that all the streams of the country would be so impregnated with those germs as to render the use of their water impossible?

A. If typhoid fever bacilli should multiply in water as do ordinary water bacteria, and if they should retain their same pathogenicity, it would seriously affect all of the surface water supplies where they multiplied, most certainly.

Q. There would certainly be no surface waters that would be safe to use as drinking water?

A. Probably there would not be.

3500 Q. Then we may reasonably conclude that the pathogenic germs such as typhoid germs, for instance, do not multiply in the water?

A. I think it is the concensus of opinion that the pathogenic germs like typhoid fever, as I say, do not multiply in water.

Q. Then the number of such germs found in water must be ascertained by the presence of the dejecta both solid and liquid, of human beings?

A. The number of such germs would not be ascertained in that way.

Q. How?

A. The number of such germs would not be ascertained in that way.

Q. Well, I will strike out the word "ascertained" and say accounted for then, their presence can only be accounted for by considering the dejecta of a human being, is that right?

A. Their presence is best accounted for by considering the probable presence of the dejecta and urine of human beings, which contain such bacilli.

Q. So that when any of these pathogenic germs are destroyed in transitu they reduce of course the possibility of transmission of disease in proportion to the number destroyed in transitu?

A. I think that is a fair proposition.

Q. Have scientists or authors upon the subject ascertained by any experiments today, the probable duration of pathogenic germs such as typhoid fever in running water? 3501

A. I don't think they have, excepting by means of laboratory experiments which naturally cannot be made under the same conditions as actually exist in running waters.

Q. Would laboratory experiments be more favorable to their existance or less favorable to their existence, than the natural water?

A. It is my opinion, speaking generally, that a laboratory experiment would be less favorable than the natural conditions.

Q. Less favorable to existence?

A. Less favorable to their longevity. Of course it must be considered that conditions alter cases; but I am speaking in very general terms, and I think you understand me in that way.

Q. Are you familiar with a work known as Micro-organisms in Water, by Percy and G. C. Frankland?

A. Yes sir.

Q. Is that a recognized authority on this subject?

A. It was at the time it was issued, and I think that it still today is considered a recognized authority, many portions of it. Of course it is understood that bacteriology has advanced considerably since that time, and I would not want to say that every statement in that book was well recognized today. Speaking generally, however, I would say that it is called an authoritative work. 3502

Q. This is the edition of 1894 that I have before me.

A. I don't know of any more recent issue.

Q. On page 294 of that book I find that the results obtained by Krans with un-sterlized waters are given in detail and in this statement the typhoid bacilli are shown to have either disappeared or at any rate to have been no longer demonstrable when the water bacteria began to assert themselves. Have you made any examinations upon that subject or upon those conditions?

A. You mean with reference to the presence of typhoid bacilli in sterilized water?

Q. No, in un-sterilized water, and the presence of the ordinary river bacteria,—water bacteria,—will they disappear in proportion of those numbers, or increase in proportion of those numbers?

A. I don't think that that can be stated because the identification of the presence of typhoid bacillus in the presence of common water bacteria is an extremely difficult thing, and it is in most instances impossible to determine the presence of a typhoid fever bacillus in the presence of a lot of common water bacteria. I know that to be true from experiments which I have made.

Q. Well at the place to which I called your attention, there is a table which refers to water taken from the Munich 3503 water supply, the river Mangfa—you are familiar with that river I presume, in which the number of typhoid bacilli found in a cubic centimeter of water as given on the first day as 57,960,

And on the second day	50,400
On the third day	15,680
On the fifth day	9,000

And on the seventh day none. There were two other samples of water taken at the same place

A. Is that sterilized water?

Q. No, unsterilized water. There were two other samples taken besides that in refrence to typhoid fever bacillus found in the water and there are three statements here in regard to the number of water bacteria found in a cubic centimeter of the same water, and it appears from those that on the first day there were none;second day none; third day none; fifth day 80; seventh day 288,000; ninth day 400,000; 20th day 970,000; these tables showing when the ordinary water bacteria began to appear the typhoid bacilli disappeared. Does that accord with the investigations which you have made upon this subject, if you have made any?

A. I should say from those results that if the common water bacteria increased as you mentioned, it was no wonder that the man didn't find typhoid bacilli in the samples at the end of seven, nine or ten days; in the presence of such numbers
3504 of common water bacteria I don't believe it is a bacteriological possibility to demonstrate the presence of the typhoid fever bacilli.

Q. He seems to have done so.

A. Apparently, from those figures I should question whether the results that he actually obtained would stand the test of the bacteriology of the present day.

Q. This subject has been very carefully considered, I presume, by scientists, the subject of the vitality of micro-organisms and pathogenic germs especially?

A. It certainly has, and the poverty of our results on the subject shows the difficulties which have been encountered in obtaining such results.

Q. Have you ever examined the investigations made in reference to the waters of the Spree, which supplies the city of Berlin, with water?

A. I believe I have seen examinations of some kind from the waters of that river; I don't recall just at present though, what they were.

Q. Well, you understood that until recently the water supply of the city of Berlin passed into the city from the river Spree, and I find in the book to which I have called your attention, a statement as to the conditions of the water before it entered the city and at a few miles below the city, after
3505 it had passed through the city, and obtained its sewage. I find it stated here that at Sacrow, which is the end of a small lake a few miles below the city, the water had resumed its normal condition before it entered the city. Have you had occasion to examine the conditions under which that purification took place?

A. I think I remember reading about the case. I am not able to recall at the present moment just the conditions, but I think you mean that the water above the city contained a certain number of bacteria, and that immediately below the city, below the entrance of the sewers, the number of bacteria was much higher, and then again further down the stream, below that lake, I think which you mentioned, or extension of the river—

Q. Havre Lake?

A. The numbers again were as low as they were above the city. I think I remember reading that fact.

Q. This lake into which the water of the Spree entered is called Havre Lake, and is several miles in length, as stated in the books, and at the end of that lake, which was only a few miles—a very few, less than ten, from the city, the water had resumed its normal purity. This was attributable in that case to the sedimentation of the bacteria in the lake. I will now ask you, after having made this suggestion, whether you
3506 have considered the question of sedimentation in the Peoria Lake, and in the other lakes in the Illinois river, and especially in the dams across that river at various points to which your attention has been called in determining whether it were possible for typhoid bacteria to be carried from the Chicago river by way of the drainage canal into the St. Louis Intake?

A. Yes, I considered the question of sedimentation in those expansions of the river to which you refer, the Illinois river, and it is my opinion that under certain conditions sedimentation of bacteria might certainly occur in those places.

Q. If for the short distance to which I have referred there was an entire disappearance of bacterial conditions, or in other words that the bacterial conditions had reached their normal condition, would it not be much more probable that such conditions would maintain in reference to the bacteria found in the Chicago River and the Drainage Canal in reaching the St. Louis intake?

A. I don't quite catch that question.

Q. (Question read).

A. The question is not just clear to me; I don't know just what you mean by the normal conditions.

Q. I mean the condition of the water before it entered the city, in reference to the Spree.

3507 A. I thought you were referring to the water of the Illinois river and Lake Michigan.

Q. Well I mean if in this distance in the Spree, the water had reached its normal condition bacterially speaking, in so short a distance by means of sedimentation and other purifying conditions, how much more likely it would be, or wouldn't it be much more likely for the water to reach its normal condition in coming the distance from the Chicago River to the St. Louis intake?

MR. JEFFRIES: Now you are assuming that it was in its normal condition at the time it started?

JUDGE SPRINGER: No, I am assuming simply that it reached the condition that it was below the city, as it was before it entered the city, and if it did that in that case, why wouldn't it do it in this case in a much more marked degree, as marked as the distance was in this case, and the distance in the latter case?

A. I think there were so many conditions that come in there that it could not be answered definitely. I can conceive that after passing through all these expansions of the river to which you have referred, the number of bacteria below them might be even lower than the number of bacteria above, but I don't think that could be definitely stated without having
3508 further knowledge in regard to the conditions that exist
at that place there, and comparing them with conditions which exist on the—

Q. Would the presence of 300,000 cubic feet of water of Lake Michigan, in diluting the sewage of Chicago, and the waters of the Illinois River, have anything to do with bacterial conditions that might appear in the Illinois River at Grafton?

A. The more the sewage of the Chicago river was diluted—I would say, the sewage of Chicago, and the Chicago river was diluted with the water from Lake Michigan, the smaller would be the number of bacteria in the water after this dilution.

Q. And the less likely would that bacteria be to produce injurious results?

A. Well, I could not say that dilution is destructive of bacteria.

Q. The probability of removing its presence?

A. The greater the dilution the less the probability would be of finding the typhoid fever bacillus, for example in a glass of water, but dilution,—mere dilution of the bacteria so far as the dilution alone is concerned, is not destructive of bacteria.

Q. But the amount of dilution increases the chances of pollution at a given point, does it not?

A. You mean decreases? Would decrease the amount
3509 of pollution?

A. The greater the amount of dilution of a polluted water, the less danger there would be from drinking this water, so far as dilution alone, is concerned.

Q. Yes, that is what I meant. I want to call your attention to an experiment in reference to the waters of the river Limmat which flows out of Lake Zurich. It is stated in the work to which I called your attention, that the average number of micro organisms in the water of Lake Zurich was from 100 to 200 per cubic centimeter. The river Limmat flows out of the lake. A sample collected below Zurich, after it had passed through the city and before it receives its drainage, showed that already in its flow through Zurich it has become more or less contaminated. The increase in the number of bacteria is however, very much more marked below the point of the sewage outfall, and after the rain or snow, has fallen, the numbers show a decided increase, and this is specially exhibited so this author states, in the experiments of January 28th, and 30th and February 15th and 16th, and other experiments being particularly instructive in this respect, as many as 24,000 micro-organisms being found at Extringingen in one cubic centimeter of water; at Dietikon, after a flow of ten kilometers, which I understand to be six miles, the bacterial condition of the water approaches very often to that of the river before the introduction
3510 of the sewage.

In view of that instance noted in this work, and assuming that the conditions stated there are true, is it not very highly probable that the waters of the Illinois river at the Narrows, above Peoria, a distance of over 100 miles from Chicago, would have obtained a bacteriological condition which those waters had before the reception of the Chicago sewage?

MR. JEFFRIES: That is objected to for the reason that the question does not state similar conditions as applicable to both places.

A. Now if you will just read that question.

Q. (Question read).

A. It is my opinion that without knowing more about the conditions which actually existed where those experiments were made, the results obtained would not be of any material value in judging as to what would be the bacteriological conditions at Peoria, but the experiments made, seem to be in line with what is generally known in regard to the decrease in the total number of bacteria in streams below points where they become polluted, and it is quite conceivable that the conditions in the Illinois river between the Chicago drainage canal and Peoria are such that the total numbers of bacteria in the Illinois River at that point might be as low, or even lower than the numbers
of bacteria in the waters of Lake Michigan before it re-
3511 ceived the sewage of Chicago, but I would add to that
that when we speak of the bacteriological condition we must consider not only the number present, but also the character of those bacteria.

Q. If the number of ordinary water bacteria decreased during this interval of time, and distance, would not the pathogenic germs decrease in like proportion?

A. The probability is that pathogenic germs would decrease, but whether or not they would decrease exactly in proportion to the water bacteria is a thing which I cannot state.

Q. Isn't it true as a bacteriological fact, that they would decrease more rapidly by reason of the presence of the water bacteria?

A. I don't know that that can be stated exactly, in natural waters, and that result appears from experimental work to be at times in the laboratory, but whether or not that actually occurs in natural bodies of water, where conditions are very different from what they are in a flask, for example in a laboratory, I am unable to state definitely.

Q. If pathogenic germs do not multiply in water, and if ordinary water bacteria do multiply in water, is it not probable that there would be a greater decrease in the number of
the pathogenic germs during an interval of time, and
3512 space through which the water traveled, than there would
be in the number of water bacteria?

A. It is conceivable that there might be but that would depend upon the character of the water bacteria and the conditions of the water. Water bacteria are not all the time multiplying in water; they are sometimes dying, and they might die and certain forms of the water bacteria might die at even a greater rate than typhoid bacilli under certain conditions.

Q. Have you ever made any experiments to determine the effect of the temperature upon pathogenic germs, and of water bacteria as to their respective longevity?

A. You mean as to how temperature effects the longevity of typhoid bacillus as compared with the longevity of water bacteria?

Q. Yes?

A. I don't know that I ever made any direct comparative experiments, but it is my general impression from experiments which have been made, that at most temperatures water bacteria would live longer in water than the typhoid bacilli, but of course that all depends upon the character of the water bacteria and the character of the water, the temperature and other considerations. I have made a good many experiments covering both phases of the subject, but perhaps never any particular one set to bring out just that one point.

3513 Q. All other conditions being equal, except the condition that the pathogenic germs do not multiply in water, and the fact that the water bacteria do, would not the probability be greater for reducing the number of pathogenic germs, as compared with the number of ordinary water bacteria during the transit of a given number of miles in a stream of running water?

A. If we neglect all other conditions, such as sedimentation, etc., etc., and consider only the fact that typhoid bacilli do not multiply in water, while water bacteria do multiply under the conditions assumed, why then is it probable that the typhoid bacilli would not linger in water as long as the bacilli which multiplied there, but as a natural practice it would not do to neglect all such other considerations in studying a problem of that character.

Q. I am only asking your opinion upon the conditions suggested; of course there might be other conditions.

A. I have given my opinion under those conditions.

Q. Are you familiar with a stream in Scotland known as the River Dee?

A. Yes sir, I have heard of it; I never saw it.

Q. The stream upon which the city of Aberdeen is situated. The book to which I called your attention, by Percy and G. C. Frankland, on pages 100, 101 and 102, referred to
3514 experiments made by one of the authors by bacteriological examinations of the waters of that river in July, 1892. I will not read the results of this as stated here, but call your attention to the fact which is here stated, among other things, that the water in the river on reaching Invercannie, which is the mouth of the river or near the mouth, exhibited just about the same number of micro-organisms as it did at the first point mentioned, and that the total number of miles of the river's flow, which were examined bacteriologically, was a little upwards of forty miles; that the distance was upwards of forty miles, and during this time, this work states that there were as many as four different sources of pollution entering the river, and that after each one the river reached its normal condition, and came out at the end comparatively, bacterially pure, as stated by this writer, the river thus affords a most perfect example of the repeated pollution and repeated restoration of a stream to a state of comparative bacterial purity.

In view of these facts which have been ascertained by an acknowledged authority on the subject of bacteriology, is it not highly probable that the waters of the Illinois river in passing from Joliet to the Narrows above Peoria, a distance of over 100 miles, were rendered bacterially or comparatively bacterially pure by reason of the sedimentation, oxidation and
3515 other causes tending to the purification of running waters?

MR. JEFFRIES: That question is objected to for the reason that the hypotheses mentioned are not the same in both cases and that the hypothetical statements do not disclose the full conditions of the various streams polluting the river Dee or that the application to be given them is the same, so that whatever answer might be made to the question could not apply with equal force in both instances.

A. It is my opinion that the conditions which exist in the River Dee, have not been described with sufficient completeness as to the amount of dilution received, in the course of the streams, the amount of sedimentation etc., which might take place, to enable a fair comparison to be made between the River Dee and the Illinois River.

Q. Doesn't the mere fact that this River Dee received pollution at four different places in the stream and that it purified itself four times during forty miles, tend to show that other streams will purify themselves in traveling a given distance?

A. It will tend to show that other streams would act in the same manner where the conditions were the same, and I may add that the result which you have described as having been obtained in the river Dee agree generally with many results
which I have observed in other streams. It is a general
3516 fact that if a stream is polluted at a certain point and
the water of that stream contained a certain number of the bacteria below that point of pollution, that a decrease in the number of bacteria is often noticed down stream due to a variety of causes.

Q. If typhoid fever should exist at the same time in cities on the banks of a given stream of water, which of the cities—the up-stream or the down-stream cities, would be in the most unfavorable condition so far as being affected by the presence of dejecta from typhoid fever patients in those streams?

A. That would depend upon the amount of the typhoid fever dejecta, discharged into the stream at various points and it would be influenced by question of dilution and sedimentation and a number of such factors. I fear, however, I don't fully understand your question.

Q. Well you have comprehended it; that is what I wanted to know. If there was an epidemic of typhoid fever in the City of St. Louis, for instance, and the dejecta of typhoid patients were cast into the Mississippi river, what effect would you conclude would be produced upon the persons living in the cities below St. Louis, which derive their water supply from the Mississippi River?

A. Well, that would depend upon the extent of the epidemic in St. Louis and upon the amount of dilution which the
dejecta might receive in the river and upon the location of
3517 the cities down stream which might receive that water, and
upon the time required for the water to pass from St.

Louis to the other city and upon the rate of dying out of the typhoid bacilli; upon the sedimentation and upon factors of that sort.

Q. Assuming that the cities on the Missouri and Mississippi rivers in the year 1890, were visited by a typhoid epidemic, of more or less extent, and the sewage of the respective cities was emptied into the Mississippi and Missouri rivers, would the pollution and the danger from the presence of typhoid bacilli increase as you passed down the streams?

MR. JEFFRIES: The question is objected to for the reason that it does not give the approximate location of the various cities, and whether it means that the danger would increase before it would arrive at certain cities, or after it had passed by certain cities, so that any answer that might be given would be indefinite and not applicable to any given state of facts.

Q. (Question read).

A. Speaking very generally, the danger of contracting typhoid fever by drinking the water of those streams would decrease down the stream.

Q. Would decrease or increase?

A. Would decrease down the stream, but in this we should
have to consider the relative amount of dilution which
3518 took place down the stream and such factors as the dying
out of the bacilli and sedimentation and other factors,
of which I have already spoken in previous answers.

Q. Then there might be conditions of sedimentation which would cause a decrease of the danger, or in the number of pathogenic germs?

A. I can conceive that if in passing down the stream the typhoid fever bacilli settled to the bottom of the stream, and if no other influences ever came about to lift them again into the water, and carry them down stream, that so far as those bacilli that would settle out, were concerned, the danger down stream would be decreased.

Q. Would be decreased?

A. Yes sir, if the bacilli settled out of the water, at a certain place, and remained there from that time on, there would be no danger from that particular bacillus down stream.

Q. Then the danger of contamination of the lower river would be lessened in proportion as the pathogenic germs were eliminated by the sedimentation and other causes to which you have referred?

A. The danger from drinking the water in the stream further down the river is certainly lessened in proportion as typhoid fever germs are actually eliminated from the water.

3519 Q. Well assume that there had been no typhoid cases in the upper city, then how would you account for the condition in the last city upon the stream?

A. What condition do you mean?

Q. As to typhoid, how would you account for the presence of the typhoid germs if there had been no typhoid cases in the towns above, how would you account for the typhoid germs in the lower river?

A. If it were true that there had been no cases of typhoid on those portions of the river above a certain point, and if it could be shown that the water at that point contained typhoid bacilli, and it must be understood that the methods of bacteriology do not admit of that to be shown, while the presence of the typhoid bacillus at that point could not fairly be considered as coming from the stream above.

Q. Some other cause then would have to be found for its presence?

A. If they were really present in the water at that point, they must have gotten in, in some way, but that is a condition which I may say is almost impossible.

Q. What condition is impossible?

A. The condition that typhoid fever exists at a certain point on the stream without their having been put into the stream either at that point or above that point. It is simply the practical proposition that if we find them there, they must have been put there.

3520 Q. They must have come from some place.

A. Yes, they must have come from some place.

Q. In the United States census for 1890, there is contained some data for cities of 50,000 inhabitants and upwards, for the year 1890, in reference to the deaths from typhoid fever per 10,000 living persons in certain cities. At Denver, Colorado, for instance, population 106,000 in round numbers, there were 21.7 deaths per 10,000 living persons;

In St. Paul there were 6.9 deaths per 10,000, with a population of 133,000;

In Minneapolis, with a population of 164,000, there were 5.7 deaths per 10,000 persons;

In Memphis, with a population of 64,000, there were 5.1 deaths per 10,000 persons;

In Omaha, with a population of 140,000, there were 4.5 deaths per 10,000.

MR. JEFFRIES: What year is that for?

THE WITNESS: 1890.

JUDGE SPRINGER: 1890; United States census for 1890.

Q. (Continuing) In Kansas City, with a population of 132,000, there were 4 deaths per 10,000 persons;

In St. Louis, with a population of 451,000, there were 3.2 deaths in 10,000;

In New Orleans, with a population of 242,000, there were
3521 1.9 deaths per 10,000.

Of these cities, Denver received its water supply from the North Platte river, a river which empties into the Missouri near Omaha; St. Paul receives its water supply from lakes near that city, and Minneapolis from the Mississippi river; Memphis receives its water supply from artesian wells; Kansas City from the Missouri river and St. Louis from the Mississippi river, and New Orleans from the Mississippi river, and Omaha from the Missouri river. All of these cities, I believe, have sewerage systems emptying into the Missouri and Mississippi rivers, except Denver, which receives its supply from the North Platte river, which empties into the Missouri. How do you account for the fact that the death rate of New Orleans, which was 1.9 per 10,000 persons, was less than it was in any of the up-stream cities to which I have referred?

A. I cannot account for it without considering a series of conditions, many of which are quite unknown to me. I can conceive it possible that in so far as the typhoid fever existed in these various cities, and in so far as that sewage from typhoid fever patients drained into these streams, and in so far as typhoid fever bacilli may have reached the water supplies of

the cities further down on those streams, that those cases of typhoid fever in the upper cities may have had some influence upon the lower, but the amount of the influence, I could not
3522 state. I do not know all the conditions which exist with regard to the decrease in the typhoid fever bacilli at the different places, or the relative effects of the sewages of the different cities on the streams below. In short, the problem is too big a one to be solved without knowing many more conditions than anything that I have at hand at this moment aside from these figures.

Q. Assuming the facts to be as stated in this data, taken from the census of 1890, is it not apparent that the sewage from typhoid patients which carried typhoid bacilli into the Missouri and Mississippi rivers, was so diluted by the waters of the two rivers, and the bacteria therein so far destroyed by sedimentation and oxidation, and by being lost on the banks and bottoms of the rivers, that they did not reach the lower Mississippi in quantities to increase the ordinary conditions which would otherwise have existed.

A. I have no doubt that starting with Denver and the Missouri river and St. Paul on the Mississippi river, and continuing down the two streams, both before and after their junction, that in so far as the bacilli—typhoid fever bacilli in the sewage of those cities were concerned, there was an increasing dilution; there may have been sedimentation; there was no doubt a dying out of the typhoid fever bacilli. On the other hand some of the bacilli which settled may have been again carried into suspension and borne a distance, pos-
3523 sibly to be again settled; possibly to be again carried on, and I should judge from these figures, that the water which was being used by the people of New Orleans, for example, was less dangerous from the standpoint of typhoid fever, than the water which was being used by the city of Memphis, for example, assuming that there were no local conditions or no other conditions to account for the difference in the typhoid fever rate. In short, the death rate from the typhoid fever in the two cities for a certain period offers a fair index for the comparison of the danger of the two water supplies for the period, irrespective of other causes which might account for some of the cases, aside from the water.

Q. In estimating the drainage area of a river or of the rivers in question here, why do you limit the population along the rivers or in the watershed to cities and towns of 4,000 inhabitants and over?

A. Did you say why?

Q. Yes?

A. Just read the question again.

Q. (Question read.)

A. I assume that you ask the question as to why we often consider only cities which have more than 4,000 population on a certain drainage area, when considering the effect of population with reference to its influence on the water supply, and to that I would say that we do not always limit it to that, 3524 but that it is my judgment that considering the population in such a way offers us on the whole a better means for comparing the effect of the population upon one watershed with the effect of the population upon another watershed, for example, than by considering the total population; for the reason that speaking generally, throughout the country, communities which have more than 4,000 population are more often supplied with such public improvements as a sewerage system and public water supply, than are those which have less than 4,000. I recognize that this is an arbitrary division, but it is one which taken broadly all over the country seems to be a fair one.

Q. At what seasons of the year is there the greatest pollution in running streams, in the dry season or the rainy season; in high floods or low floods?

A. That depends upon what you mean, just how you would define pollution, and upon the character of the stream and upon the time when the polluting matters and substances might enter the stream.

Q. I refer to those kinds of pollution which render a given river unsuitable as a water supply for a city or town; in view of that fact, when is the time of the greatest pollution of the waters of such a stream?

A. It depends in part upon the constancy of the pollution. If there is a sewer, for instance, running constantly into a 3525 stream, the relative proportion of the sewage to the flow of the stream would be less in time, of low flood than at times of high flood; but on the other hand, there may be streams where at times of high flood the pollution is greater than at times of low flood.

Q. Do not scientists universally recognize as a fact that the greatest pollution in streams of water is at times when the flood is the greatest, or the flow of the water is the greatest?

A. No, sir; I should not think that was universally recognized as a fact.

Q. It is not?

A. I should not think it is universally recognized as a fact, no, sir.

Q. What do you regard as the fact?

A. I don't think that any broad fact like that can be established.

Q. When the spring floods come into a river, and the washings from the small tributary streams are brought into the main channel, and the farms and barn-yards, and feeding pens are washed, and the sewage accumulating in the small villages, where they have no drainage system, is washed into the stream, as is usual—is not the pollution greater at such times than at any other season of the year, especially when the water is at a normal stage?

3526 A. In so far as that kind of pollution is concerned, and in so far as that kind of polluting matter is washed into the streams by the villages, I believe that is true; that, however, is not the only kind of pollution which may pollute a stream, and therefore I should want to consider that fact before assuming to draw any general conclusion. As I stated, I do not think any general conclusion can be drawn as to the relative pollution of streams at different seasons. It depends upon conditions in the different streams.

Q. Well, the conditions in most of the streams are so similar that in times of high water, when the spring rains come in, the sewers are flushed and fields washed out; isn't that the time of greatest pollution in a river?

A. At such times there might be a greater amount of polluting matter washed into the streams, but on the other hand at such times the volume of water is usually large, and dilution greater so that the result might not be different from what would occur under normal conditions; with the constant pollution of the stream by a sewer, for instance.

Q. Well, there would be some increase then by reason of all these conditions, taking place, to which I have referred?

A. No doubt there would be in some instances, but I can conceive of cases where there would not, and as I said, it must be decided according to the case in question.

3527 Q. Then in so far as the spring floods would increase the sewage in a given stream, if it would increase it to that extent should not the fact of the possible pollution of streams by reason of smaller towns than those having 4,000, and the rural districts, be taken into consideration in determining the population of a given area or given stream of water?

A. It might be desirable to consider those conditions, but they should also be considered in connection with questions of pollution, etc.

Q. Is there any means of determining bacteriologically or chemically the presence or absence of pathogenic germs in running water?

A. I don't believe that there is any practical method by which pathogenic germs can be determined in water, either chemically or bacteriologically.

MR. JEFFRIES: What do you mean by that, Judge, in river water running water—natural water?

JUDGE SPRINGER: Yes I mean in waters taken from the streams.

THE WITNESS: That is what I understood; the natural water.

Q. Natural water taken from the river?

A. Yes, sir.

Q. Couldn't that water be used for peritoneal injections into animals for the purpose of determining the presence of pathogenic germs, and would not such investigations determine to some extent the presence of pathogenic germs in natural water? 3528

A. To some extent it might determine the presence of germs in water which were pathogenic to the animals experimented with, but there may be micro-organisms pathogenic—there may be bacteria pathogenic to certain animals which would not be pathogenic to human beings, and to that extent the results of the determination would be of less value.

Q. Then if I understand you correctly you are of the opinion that it cannot be determined with certainty whether there are typhoid germs in natural running water?

A. I believe it to be a fair statement to say that in ordinary natural running waters, there is no practical method by which the presence of the typhoid fever bacillus can be determined. I do not think that it is absolutely impossible to do so, but there is no practical every-day method for doing it.

Q. If it is impracticable to ascertain the absence of pathogenic germs in the natural water, it would be equally impractical to ascertain their presence in the same water?

A. I consider the two propositions as practically one. The germ may be there and you might fail to find it; and it might not be there when you failed to find it.

Q. It does not depend upon whether you find it or not, but whether you can ascertain its presence by any chemical 3529 or bacteriological means, or any other means?

A. I stated that I do not consider that there is a practical method by which the presence or the absence of the typhoid fever bacilli can be ascertained in natural waters by chemical or bacteriological means.

G. C. WHIPPLE.

Adjourned until 10:00 a. m., Monday, May 18th, 1903, at Southern Hotel.

3530 Southern Hotel, St. Louis, Missouri. 10:00 a. m., Monday, May 18th, 1903. Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE

resumed the stand for re-direct examination by Attorney-General Crow, and testified as follows:

Q. Speaking as an expert, do you or do you not consider that the liquid leaving the Chicago drainage canal at Lockport is polluted?

JUDGE JOHNS: Objected to as not re-direct examination on any point made in the cross-examination.

A. I certainly believe it to be polluted.

JUDGE SPRINGER: What is the answer?

A. I believe it to be polluted.

GENERAL CROW: Assuming that the volume of flow of the liquid leaving the Chicago Drainage canal is 300,000 cubic feet per minute, and further assuming that at times the natural flow of the Illinois river just above Peoria is as low as 40,000 cubic feet per minute, state the percentage of diluted sew-
3531 age in the Illinois river just above Peoria, under these conditions?

JUDGE JOHNS: Objected to for the same reason as above.

JUDGE SPRINGER: I object further for the reason that it leaves out of the assumptions that should be presented to the witness the question of what amount of this sewage, if any, would be lost or absorbed or disappear in its transit from the drainage canal to Peoria.

MR. TODD: I object to it on the ground that the assumption of 40,000 cubic feet per minute at Peoria has not been established by the evidence, and it concludes a fact that has not been put in evidence.

A. If we consider that the liquid which leaves the Chicago drainage canal at Lockport to be polluted sewage and to be flowing at the rate of 300,000 cubic feet per minute, and if to that is added 40,000 cubic feet per minute of diluting water, the sum of these two amounts would be 340,000 cubic feet per minute, and of this sum about 88 per cent would be the diluted sewage.

Q. Is it or is it not possible for you to state whether the contamination of the water supply of Chicago at the intake cribs of said city, is at times appreciable?

JUDGE JOHNS: I object for the same reasons as to the first question.

MR. TODD: I object to the question on the ground that
3532 the witness has not shown that he is in possession of sufficient facts upon which to predicate an opinion, and on the further ground that appreciable is a relative term that does not have any bearing upon the investigation here.

GENERAL CROW: Go ahead.

A. I believe that at times the pollution is appreciable.

MR. TODD: I move to strike out the answer as not responsive.

Q. Now I will ask you this question: Assuming that an epidemic of Asiatic cholera should occur in the city of Chicago, under existing conditions, is it possible that the germs of that disease might find their way into the intake tower of the St. Louis waterworks at the Chain of Rocks?

JUDGE JOHNS: Objected to on the part of the State of Illinois for the same reason as to the first question.

MR. TODD: I object to it on the ground that the witness has not qualified as an expert on Asiatic cholera, and as far as the evidence goes has not shown that he has any knowledge of Asiatic cholera which would enable him to express an opinion such as is asked.

A. Just read that.

(Question read.)

A. Under the assumptions made, I believe that it is possible that those germs might find their way to the intake of the St. Louis waterworks.

3533 Q. Why?

A. Because I do not believe that there are any existing artificial or natural agencies which would at all times insure the prevention of these germs reaching the intake.

Q. MR. JEFFRIES: Mr. Whipple, you stated substantially that the banks of the Mississippi river from Grafton to the mouth of the Missouri are straight, and form what is known as a straight reach. Now I will ask you if you know whether the channel of the river between the points stated, changes from side to side, and if so, how many times, and what effect do they have on the mixing of the waters of the Illinois and the Mississippi rivers?

A. I believe that I stated that the—

MR. TODD: Wait, just read that question.

(Question read.)

JUDGE JOHNS: Objected to by the State of Illinois for the reason given in the objection to the first question.

JUDGE SPRINGER: The Sanitary District makes the same objection to this question as to the other questions asked of the witness this morning.

MR. TODD: Further, that this matter was not gone into in chief and is not a proper subject for re-direct examination.

A. Shall I answer?

MR. JEFFRIES: Yes.

A. I believe that I have stated that the banks of the river
3534 between the points mentioned, were practically straight,
barring certain sinuousities—I forget just the expression which I used. Now I know that the channel does change from side to side a number of times during that reach of the river, as I recall it, some five or six times, passing from a position near the right bank to a position near the left bank—I haven't answered the latter part of your question.

As to the effect which this changing channel would have on the mixing of the water, I believe that it would tend to assist the mixing of the Illinois river water with the water of the Mississippi river, and that a greater mixture would naturally occur than if the channel formed a perfectly straight line during that reach.

Q. You have stated that the Mississippi river had two sharp bends in it between the mouth of the Missouri river and the Chain of Rocks intake tower of the St. Louis waterworks; now I will ask you to say what in your opinion is the effect of the mixing of the Mississippi and the Illinois waters during their flow from the mouth of the Missouri to the Chain of Rocks of the St. Louis waterworks?

A. I believe that just as these bends would tend to increase the mixing or the commingling of the waters of the Mississippi river with the waters of the Missouri river, so it would also
tend to mix the waters of the Illinois river with the waters
3535 of the Mississippi river, and with those of the Missouri
river.

Q. Speaking as an expert, are you able to state whether or not it is possible for the Illinois river water at all times to flow from Grafton to the Chain of Rocks, and by the Chain of Rocks without some of it reaching the intake tower of the St. Louis waterworks?

JUDGE JOHNS: Objected to for the same reasons as above mentioned, to the first question.

A. I don't think that it is possible.

Q. Possible to what?

A. For the water of the Illinois river to pass down by the intake of the St. Louis waterworks at all times without some of the water of the Illinois river reaching the point in the river where the intake of the St. Louis waterworks is located.

Q. Assuming that the minimum stream flow of the Mississippi river at the Chain of Rocks is at times as low as 40,000 cubic feet per second, and assuming that the flow of the Chicago drainage canal is increased in the future from 5,000 cubic feet per second to 10,000 cubic feet per second, state what in your opinion would be the effect of such increase upon the amount of infectious material which may reach the Chain of Rocks, intake tower of the St. Louis waterworks?

MR. TODD: I object to the question on the ground that the facts assumed in the question have not been proven and for the further reason it is not re-direct examination. 3536

A. Shall I answer?

MR. JEFFRIES: Yes.

A. It is my opinion that under the increased conditions of flow there would be a material increase in the liability of infectious material to reach the intake tower of the St. Louis waterworks from the Chicago Drainage Canal.

Q. Under the conditions of relative flow of Mississippi river water and of the Chicago Drainage Canal, as stated in the last question, what effect will that produce regarding the mixing of the Illinois water with that of the Mississippi and Missouri water?

MR. TODD: I object to the question for the same reasons stated in the last objection.

A. I should say that it would tend to increase the proportion of Illinois river water which would become mixed with the water of the Mississippi river.

Q. Having the analyses of three samples of water, as follows: Total residue on evaporation, 170; dissolved residue, 138; suspended, 32; nitrogen as ammonia total, unfiltered, 156; filtered blank—

A. Pardon me just a minute. Albuminoid ammonia, did you say 156?

Q. Yes, .156.

3537 MR. TODD: You didn't say albuminoid ammonia; nitrogen as ammonia.

MR. JEFFRIES: That is nitrogen as ammonia; total, unfiltered, .156; filtered, blank; free ammonia, .040; albuminoid, total, .116; dissolved, blank; suspended, blank. As nitrites, .002; nitrates, .12; oxygen consumed, unfiltered, 2.2; filtered, 1.6; chlorine, 6.0; alkalinity, 117.0.

The second sample, total residue on evaporation, 321; dissolved, blank; suspended, blank; totals blank; loss on ignition, dissolved, blank and suspended blank. Nitrogen as ammonia, total, unfiltered, .754; filtered, .634—

A. What is that filtered?

Q. Yes, filtered nitrogen as ammonia. Free ammonia, .278; totals, albuminoid, .476; dissolved, .356; suspended, .120; as nitrites, .06; and nitrates, .9; oxygen consumed, unfiltered, 7.2; filtered, 6.7; chlorines, 16.0; alkalinity, 151.

Sample 3.—Residue on evaporation, totals, 305; dissolved, 273; suspended, 30; loss on ignition, total, 130; dissolved, 100; suspended, 30; nitrogen as ammonia, total unfiltered, .346; filtered, blank; as free ammonia, .092, totals, .254; that is total albuminoid, .254; dissolved albuminoid, blank; suspended, blank; as nitrites, .047; nitrates, .45; oxygen consumed, unfiltered, 5.1; filtered, 4.4; chlorine, 26; alkalinity, 162, all of which are assumed to represent mixtures of pure water and diluted sewage from the same city. Will you state solely from the standpoint of the water analyst, how they rank in regard to dilution of the sewage? 3538

JUDGE JOHNS: Objected to as not proper re-direct examination.

A. Now I wish you would read once more, if you will, the results for the nitrogen.

MR. JEFFRIES: Just read the whole question.

(Question read.)

A. If these three samples are supposed to represent different mixtures of a pure water and sewage, I should think that, so far as dilution alone is concerned, that sample No. 1 contained the least sewage, and that sample No. 2 contained more than sample 1, but less than sample 3, and that sample No. 3 contained the most. Speaking solely with respect to dilution.

Q. On the same basis what would you say was the approximate relative dilution of sewage in the three samples?

A. Speaking of dilution alone, I should consider the chlorines given in the three analyses as giving the best index of the degree of dilution, and I should say that the dilutions of sewage varied approximately according to the figures which represent the chlorines, which were 6 in the first sample, 16 in the second and 26 in the third. That would not be an exact ratio, but it
would be, for practical purposes it would give us the de-
3539 sired result.

Q. If informed that the first sample represents Chicago water from the tap at 2421 Dearborn Street Chicago, and that the second and third samples represent water taken from points on the Illinois river, would your general conclusions be changed?

MR. TODD: I object to the assumption on the ground that the facts contained in the assumptions have not been proven.

A. Since I was interpreting the results purely from the standpoint of the water analyst, why under the assumptions named in the previous question, it would make no difference where the samples came from.

Q. If water of the character of sample No. 1, that is known to have produced typhoid in the city of Chicago, and samples 2 and 3 are mixtures of this water, and the diluted sewage of Chicago, what do you say as to the probability, considering dilution alone, of these latter samples producing typhoid fever if used for domestic and drinking purposes?

MR. TODD: I object to the question on the grounds that there has been no proof offered in this case to sustain the assumption that waters or samples of waters have been known to produce typhoid fever in the city of Chicago as indicated in the hypothesis, and on the other ground that there is no evidence in the record establishing the facts upon which this hypothetical question is based.

JUDGE JOHNS: The State of Illinois objects for the

3540 same reason as to the first question propounded to the witness this morning.

A. I do not understand what samples you mean by having produced typhoid fever in the city of Chicago. I cannot compare samples 2 and 3 with samples from the city of Chicago which I do not know anything about.

Q. Well, if water of the character of sample No. 1.

A. Oh, of sample No. 1.

MR. TODD: Is it sample No. 1 that produced typhoid fever in Chicago?

MR. JEFFRIES: Yes, that's it.

MR. TODD: I also further object on the ground that no evidence has been offered in the case to substantiate the assumption that sample No. 1 at 2421 Dearborn Street in the city of Chicago has ever been the cause of typhoid fever.

A. Why, if water of the character of sample No. 1 has been the cause of typhoid fever, and if this sample be compared with samples Nos. 2 and 3, which, according to the analyses and the previous assumptions indicate a less degree of dilution with the sewage, it would be my opinion that there would be more chances of samples 2 and 3 causing typhoid fever than sample No. 1, so far as dilution is concerned.

Q. In your opinion, is the water of the Mississippi river below the mouth of the Illinois and above the St. Louis 3541 waterworks intake at Chain of Rocks, less valuable for drinking purposes now than before the emptying of the drainage canal waters mixed with Chicago sewage, into the Illinois river?

A. Read that again.

(Question read.)

JUDGE SPRINGER: You mean before January 17, 1900, do you?

MR. JEFFRIES: Well, before the opening of the drainage canal, January 17, 1900, yes.

MR. TODD: I object to the question on the ground that the value of the water of the Mississippi below the Illinois and above the intake, prior to the opening of the drainage canal has not been offered in evidence in this case; and for the further reason that the witness has not shown himself qualified from any facts, to pass upon the relative value of the waters of the Mississippi river prior to the opening of the canal, and since the opening of the drainage canal, and for the further reason that the value of water for drinking purposes is an unscientific term that expresses nothing.

JUDGE JOHNS: The State of Illinois objects to the question for the reason given in the objection to the first question.

A. Just read that question again.

Q. (Question read.)

A. It is my judgment that it is less valuable.

3542 RE-CROSS-EXAMINATION, By Judge Johns.

Q. What experience have you as to the direction and flow of currents of streams?

A. In general?

Q. Yes.

A. I know about them from many personal observations and from many studies of literature on the subject.

Q. Suppose that the current of a stream in its deepest part runs close to a precipitous curved bank of a river at the rate of three miles an hour, when it comes to a point where the river is again straightened, would the current go across the river or follow around the bank?

A. Do I understand you to assume a condition where there is a curve followed by a straight reach, if I may use that expression?

Q. Yes.

A. And where the current at the curve is near a precipitous bank?

Q. Yes.

A. It might follow along the straight reach, and on the other hand it might be deflected to some extent across the stream again.

Q. Well, it might do either one of the two things, follow
3543 along the bank in a straight reach, or go across?

A. It is possible—there would, without doubt, be a slight deflection that would be the natural condition.

Q. Is there any certain law about it?

A. That depends something upon the varying cross-section of the stream, so far as any general law is concerned, there would tend to be a slight deflection of the current across the stream again.

Q. Well would the main body of water in the channel follow the bank or go across the stream?

A. Of course the water would be kept between the two banks. If the main current of the channel tended to cross the stream, and if the cross-section of the stream were such as to allow it, there might be a slight tendency for a considerable part of the volume of the water to cross the stream. Perhaps I don't exactly understand your question.

Q. Assuming only and solely that the current of a stream in its deepest part, flowing at the rate of three miles an hour, is immediately adjoining a precipitous bank in a curve, and that below the curve there is a straight reach of the river, where would the current of the river go, immediately down the straight bank of the stream, or across it?

A. Well, on a uniform cross-section, I believe it would tend to re-cross to some extent. I do not believe that it would keep exactly to a straight line along a straight reach under the assumed conditions of a uniform cross-section. 3544

Q. Have you any more familiarity with the character of the Mississippi on this 18th day of May than you had on the 16th of the same month, as to its curves and bends and reaches between here and Grafton?

A. Well, practically not.

Q. You never have been on the Mississippi river between here and Grafton, have you?

A. Not between the Chain of Rocks and Grafton.

Q. Not between the Chain of Rocks and Grafton?

A. No sir.

Q. Where did you derive your knowledge of the banks and curves and reaches of the Mississippi river between the Chain of Rocks and Grafton?

A. From several maps, among them the Government charts, the charts of the Mississippi river commission.

Q. Of what date?

A. I don't recollect the date.

Q. The same charts which you examined in reference to the cross-sections in your examination in chief—cross-sections for turbidity?

A. Yes, that was one of the charts; I examined several others; it required several sections of charts to cover the entire distance.

3545 Q. Do you know whether they were of the same date or not?

A. I don't recollect.

Q. You don't know whether any of those charts were within the last five years, do you?

A. I don't think they were within the last five years.

Q. Do you know whether any of them were in the last ten years?

A. I don't think they were. I know not to what extent they have been revised, but I think they were made along in the eighties.

Q. Do you know whether those charts represent the condition of the banks and the curves of the Mississippi river in January, 1900?

A. Not exactly, but I believe that, speaking generally, they so represent them. I have no doubt that there have been slight changes.

Q. What reason have you to believe that, speaking generally, they represent them; do you not know that the currents of the Mississippi river and the banks change constantly, and with great rapidity, and with great frequency?

A. I understand that they do change from time to time; sometimes rather suddenly.

Q. What is the cause of it?

A. Due to the variations in the flow of the stream, due
3546 perhaps to the cutting away of some of the banks.

Q. Cutting away of the bank would be because of the sudden change in the current, would it not, and channel?

A. It might be a change in the direction of the current or in the amount of the current, amount of flow; the change would also be due to the deposition of sediment perhaps.

Q. Your knowledge, then, of the probability of the waters of the Illinois river reaching the intake of the St. Louis waterworks at Chain of Rocks, is derived from an examination of Government charts made some time in the years from 1870 to 1880, and not from any later data so far as you now know, and from no personal observation or knowledge of your own?

A. My knowledge is not derived from a personal inspection of the river, in that reach, but from various maps and charts, among them the Government charts which were made on dates which I do not just recollect, but not very far, I believe from the dates you mention.

Q. Assuming that the volume of the Illinois river at Peoria before the opening of the drainage canal, given you, namely, 40,000 feet per minute—is the volume at the lowest known water, the lowest known stage of the river at any time within the last 25 years, would you think that assumption fair, upon which to make a calculation of the percentage of dilution?

A. It would be fair with reference to that particular time.

3547 Q. Assuming that at all times since that data was given, the volume of the Illinois river has been greater and that it has at Peoria at some times been as much as 2,000,000 feet per second, would you be able to form any opinion as to the percentage of dilution at any other time than the exceptional time given you in this supposititious question?

A. Why no, I could form simply an opinion of the dilution at the time when the figures were given.

Q. Assume that below the Peoria Narrows, and between there and Grafton, at the mouth of the Illinois, there is a very much greater dilution of the waters of the Illinois river from its tributaries than above Peoria, would your conclusion as to the possibility of the waters in the Illinois river above Peoria reaching Grafton in the state in which they were above Peoria, be in anywise changed?

A. Why, I should want to know the relative amount to which the water was diluted below Grafton, in so far as dilution was concerned.

JUDGE SPRINGER: You mean below Grafton or below Peoria?

A. Below Peoria, between Peoria and Grafton, as compared with the dilution above, and that would affect simply the question so far as the dilution was concerned; that would not influence other factors which might influence the water, in its passage in the Illinois river.

3548 Q. Well, sewage may be rendered harmless by proper dilution, may it not, that is harmless to health?

A. I would not say that in such plain terms, no sir, so far as that alone is concerned, you understand.

Q. If a cubic foot of sewage is diluted with 300,000 cubic feet of good water, the danger of disease from that sewage thus diluted would be either nothing or very small, would it not?

A. That would depend upon the character of the sewage. The danger would be certainly very much less than that from the sewage itself.

Q. If sewage was diluted in the proportion of one foot of sewage to 45 feet of pure water, or good water, that amount is above the ordinary requirements of sanitarians, as to dilution, is it not?

A. One cubic foot of sewage diluted with 45 cubic feet of pure water?

Q. Yes?

A. No sir, I shouldn't call it above the requirements.

Q. What are the requirements of scientists as to the dilution of sewage with good water so that the water might become potable?

A. I know of no exact requirements, and furthermore, the
word "potable" as I have previously said, in testimony,
3549 does not convey, to my mind, a definite meaning.

Q. Have you any word which expresses your idea of water which it is safe to drink, other than the word "potable"?

A. I just use the word "safety."

Q. You prefer to use the word "safety"?

A. I prefer the word "safety" meaning safety from danger of contracting disease from drinking water.

Q. Can water which is polluted with sewage, be diluted to such an extent that it is safe to drink it?

A. It can be diluted to such an extent that the chance of contracting disease by drinking the water is very remote. I don't think that simply by dilution alone you can absolutely say that it can be rendered safe at all times.

Q. Then the greater the dilution the less the chances of harm?

A. That is certainly true, as far as dilution goes.

Q. Assuming that the city of Chicago had for fifteen years prior to 1900, discharged into the Illinois and Michigan canal substantially the same amount of sewage that has been discharged by the drainage canal into the Illinois river since 1900, with a dilution of only 40,000 feet per minute, would you think that that sewage had, during that fifteen years, reached the intake at St. Louis?

3550 MR. JEFFRIES: The question is objected to for the reason that it does not contain an hypothesis stating or showing that the sewage was carried through the old Illinois and Michigan canal in the same length of time as through the present Chicago drainage canal.

A. Read the question once more.

Q. (Question read.)

MR. JEFFRIES: I object for the further reason that the question does not assume that the sewage matter thus discharged was practically the same when it entered into the Illinois and Michigan canal as it is when it enters the Chicago drainage canal today.

A. So far as dilution is concerned, or rather, in so far as your assumption takes into account only dilution, I could not give a definite reply to that. Perhaps you had better read that question again. I think I have answered it.

Q. (Question read.)

A. Do I understand that you assume any other conditions than dilution? Do I understand that you wish me to take into account any other conditions than dilution?

Q. No sir, only the conditions stated in the question?

A. Read my answer again.

(Answer read.)

Q. Well, go ahead?

A. That wasn't what I meant. In so far as dilution is

3551 concerned, without considering other factors, I believe it might be possible—how do you express that first part of it?

Q. I just want to know whether if it goes into 40,000 feet of dilution in the Illinois river it is just as likely to reach the intake as with 300,000 feet of dilution?

A. I understand that you made no comparison; I understood you to ask if it did?

Q. Yes sir.

A. And I believe that so far as dilution goes, it might.

Q. Well, if the waters of the Illinois river, to which are added 300,000 feet of water from Lake Michigan, certainly reach, in your opinion, the intake at St. Louis, why wouldn't the waters of the Illinois to which were added 40,000 feet, as certainly reach the intake at St. Louis?

A. I think that so far as dilution alone is concerned they might as certainly reach, so far as dilution is concerned.

Q. But if for 15 years prior to 1900, substantially the same amount of sewage discharged into the Illinois river from Chicago, diluted with 40,000 feet of water as is discharged since 1900, diluted with 300,000 cubic feet of water, then the danger of disease in St. Louis from the sewage of Chicago, diluted with 40,000 feet of water, would be more than seven times as great as if diluted by 300,000 feet of water, would it not?

3552 MR. JEFFRIES: I object to that question for the same reasons stated in my objection to the previous question.

A. In so far as dilution itself is concerned, that would practically be the case, so far as dilution itself is concerned; dilution is a good thing.

3553 Q. When was Asiatic cholera in Chicago?

A. I don't know.

Q. Do you know whether there ever was any there?

A. No sir.

Q. You are not aware that there was Asiatic cholera in Chicago or so-called Asiatic cholera in 1847, and that there has been none since?

A. I don't know that.

Q. Is Asiatic cholera, considering the latitude and longitude of Chicago, at all likely to occur there?

A. As far as the latitude and longitude go I think it might occur there, yes.

Q. Independent, then, of latitude and longitude, taking into consideration any other element, is it likely to occur in Chicago?

A. So far as the latitude and longitude are concerned, I think it might occur there.

Q. Now with all the other conditions added do you think it likely to occur?

MR. JEFFRIES: What other conditions?

JUDGE JOHNS: I don't know.

A. That would depend upon other conditions; it is quite conceivable that cholera might occur in the city of Chicago.

3554 Q. On the doctrine of probability, if there is any such thing, is it probable that Asiatic cholera would ever occur in the city of Chicago as an epidemic?

A. I think that would depend wholly upon circumstances. I think if any of our health officials in most of our cities, particularly the sea-coast cities, did their duty, this country ought not to be visited by cholera, but I cannot say and no one can say when cholera might not occur in this country.

Q. Could the Asiatic cholera occur in Sitka, Alaska?

A. I could not definitely say that it would not, but I don't think it would be likely to occur in such a northern situation as that.

Q. Could it occur in Vancouver, British Columbia?

A. I think it might occur there.

Q. Asiatic cholera has somewhat of a geographic limit owing to climate, has it not?

A. I think it is more likely to occur in warm climates and temperate climates, than in extreme northern climates, but I cannot draw any line, and I don't believe scientists could draw any definite line of why or where, or just how far north it could not or can occur.

Q. When you say that the pollutions in the Illinois river are sometimes appreciable, at the intake and at the Chain of Rocks, to what extent do you mean appreciable?

A. I mean that if the Illinois river is polluted that that

pollution may reach the intake at the chain of rocks, but
3555 I cannot state the extent to which it would reach the Chain of rocks, or when it would.

Q. Can you say whether it would at all times?

A. I cannot say whether it would at all times.

Q. Can you designate the season at which it would be appreciable?

A. I cannot definitely, because it depends upon a number of conditions with reference to the flow of the streams, with reference to the amount of pollution; with reference to mixing and sedimentation and all those factors which we have discussed.

Q. At what season of the year is typhoid fever the most prevalent?

A. As a rule it comes in the latter part of the summer and early fall. Speaking of it generally without regard to exceptional epidemics.

Q. In a general way it comes in the early fall?

A. Yes, in this hemisphere, and in the other hemisphere it is the other way around.

Q. Could you tell or do you know whether the pollution in the Illinois river was appreciable at the intake of the St. Louis waterworks in the fall of 1902?

A. I couldn't say definitely.

Q. Or any other year?

3556 A. I cannot say definitely that it was, but I see no reason why it might not be at times.

Q. Do you mean by appreciable, simply capable of being perceived by scientific examination?

A. No sir, I mean appreciable from a practical standpoint that it may have an effect upon the health of the people who drink the water.

Q. Do you mean to say that it does as a matter of fact have an effect upon the health of the people?

A. I cannot say absolutely that it does, but I believe that possibility certainly exists.

Q. It is a possibility that it might?

A. I believe that it is.

Q. Do you believe that the waters of the Missouri riv have an appreciable effect upon the character of the water at the St. Louis intake?

A. I cannot say absolutely that they do, but I believe that they may.

Q. Do you not know that they absolutely do have an appreciable effect upon the character of the water at the St. Louis intake?

A. I couldn't say that they absolutely do.

Q. To what do you attribute the extraordinary amount of matter in suspension in the waters of the intake, the Missouri the Mississippi, or the Illinois?

3557 A. I believe that it comes largely from the Missouri river.

Q. If typhoid fever germs were discharged into the Missouri river, the Mississippi river and the Illinois river at such times that the waters into which they were discharged would reach the chain of rocks simultaneously, and in consequence thereof, typhoid fever ensued in the City of St. Louis, to what would you attribute the typhoid fever?

MR. JEFFRIES: That is, I understand that they all reach the intake at the same time?

JUDGE JOHNS: Yes, all go in the same date.

A. If there were typhoid fever germs reaching the intake on a certain date from the Missouri river, and if there were others reached the intake from the Mississippi river and others reached it at the same time from the Illinois river, and if these germs caused typhoid fever in the city of St. Louis, I couldn't say exactly which one of the three or whether all of them caused the typhoid fever, and I couldn't tell the relative number of cases which each one caused without knowing more about the number of germs that came from each one.

Q. If under the conditions supposed in the former question the typhoid germs from the Missouri river traveled 40 miles, and the typhoid germs from the Mississippi 100 miles and the typhoid germs from the Illinois 350 miles, which set of 3558 germs would be most likely to cause the typhoid fever, supposed in the former question?

MR. JEFFRIES: That is still supposing that they all reached there at the same time?

A. Yes, you couldn't tell from those figures alone, in so far as those distances affect the time required for the germs to travel, and in so far as that time alone affected the germs, you would naturally expect a greater effect from the nearer one, but that would have to be taken into consideration with many other factors.

Q. Suppose that the time of transmission to St. Louis was proportionate to the distance named in the former question; to which one would you attribute the typhoid fever in St. Louis?

MR. JEFFRIES: Proportionate to the distance did you say?

JUDGE JOHNS: Yes.

A. So far as that fact alone, disregarding everything else, you might naturally expect—disregarding the numbers and those other factors and considering the question of time, why that those nearest might be considered as having the greatest effect, but in making a true comparison you would have to compare all factors; you couldn't compare that alone.

Q. In you answer to the questions propounded this morning, as to samples 1, 2 and 3, did you suppose an equal amount of pollution in the water in each event?

3559 A. I don't understand what you mean by that. I assumed that those were different mixtures, or that those were a mixture of a certain water in a certain sewage, in different proportions.

Q. From what question propounded to you did you arriv at that assumption?

A. That is what I understood the question was, one of the questions asked by Mr. Jeffries, I think it was.

Q. What would be the effect upon your judgment as to samples 1, 2 and 3, if they were equally diluted with pure water?

A. To what extent?

Q. As to the percentage of sewage in it.

A. I don't understand what you mean.

MR. JEFFRIES: I think he means if the same amount of sewage was in each sample.

JUDGE JOHNS: What did you understand the assump tions were in the questions propounded to you by Mr. Jeffries, as to samples 1, 2 and 3?

A. I understood that these three samples represented three different mixtures of sewage and water. In one there was such a pollution—these three different mixtures, and I was asked to state which in my opinion showed the greatest pollution; in other words to state what the relative mixtures were, as to whether one contained a larger proportion of the sewage than the other.

3560 Q. You were answering as to whether one was more largely diluted with pure water than the other?

A. Yes, the pure water in question.

Q. On that basis, did you explain that sample 1 had the most dilution?

A. Yes, sir; more than the other two.

Q. And sample 3 less dilution than sample 2?

A. Sample 3 was less diluted than 2, they were in the order 1, 2 and 3.

Q. Did you assume as to those matters that the same amount of sewage existed in each sample in weight or volume, and of the same character?

A. No, sir; that was a practical question. That was practically what was supposed to be determined by comparing analyses as to which had the greater amount of sewage?

Q. Did you assume that each sample contained an equal amount of water, or that each sample was of equal volume or weight?

A. I supposed we were comparing equal volumes. These results were expressed in parts per million by weight.

Q. The results of the chemical analyses of the samples were expressed in parts per million?

A. Yes, sir.

Q. You understand, that is, from equal volumes of the samples submitted?

3561 A. Yes, expressed in terms of equal weight, which means practically the same thing.

Q. Your opinion is then, that there was greater dilution in sample 1 than in sample 2?

A. Yes, sir.

Q. And greater dilution in sample 2 than in sample 3?

A. Yes, sir.

Q. Do you know at what point in the river samples 2 and 3 were taken?

A. I don't know where they were taken. I think in one question he assumed that they were taken at certain points.

MR. JEFFRIES: The assumption was that they were taken in the Illinois river.

JUDGE JOHNS: Do you care to tell me where, Mr. Jeffries?

MR. JEFFRIES: I don't know.

THE WITNESS: As I understand, this was an assumption.

JUDGE JOHNS: You don't know whether sample 2 is taken at all; is anything more than a supposition, as taken above or below Peoria?

A. I consider these three analyses as a supposition, but in one question he assumed that sample No. 2 was taken at or above Peoria; I have forgotten which. I understand that it is an assumption.

Q. You have no knowledge as to whether the other two samples are anything more than a supposition?

3562 A. I couldn't say whether they are anything more than a supposition from the question.

Q. Did you select these supposed chemical analyses of three supposed samples, and give them to the attorneys for the State of Missouri for the purposes of this supposition?

A. No, sir.

Q. Do you know who did?

A. I thought I saw Mr. Fuller and Mr. Jeffries looking over the record together; I don't know which one of them picked them out. I don't know really whether they picked them out or not. I saw them looking over the records.

Q. Do you know whether they were looking at the record in this case?

A. It looked like one of the sheets of complainant's Exhibit 1 for identification.

Q. But whether or not it was, you don't know now?

A. I did not definitely examine the paper with that idea.

Q. Suppose sample No. 2 was taken above Peoria and represented fairly the quality of the water at that point at a given time? By the time that water reached Grafton it would be vastly changed, would it not, if nothing in the way of pollution were added to it?

A. I should suppose that it would be changed, under existing conditions.

3563 Q. The process of nitrification would have changed the constituents of that sewage very largely by the time it reached Grafton, if it was taken above Peoria?

A. It might change it.

Q. Would it not as a matter of fact, actually change it?

A. It practically would have changed it to some extent, yes.

Q. Wouldn't it have changed it to a very considerable extent?

A. I couldn't say to how considerable an extent.

Q. Would it have changed it for the better or for the worse?

A. Speaking in broad terms, I suppose somewhat for the better.

Q. If sample No. 3 was taken below Peoria and represented correctly the condition of the water in the Illinois river at the time it was taken, its character also would have changed in its journey down the river to Grafton, would it not?

A. I presume it would have, yes.

Q. And for the better as far as the safety of the water for drinking purposes is concerned?

A. I couldn't say—you were speaking about nitrification; I couldn't say that without knowing the conditions.

Q. I am speaking now of nitrification?

A. As far as nitrification is concerned, it would become better water, using that word "better" in a very general sense.

3564 Q. If after the arrival of these two conditions of water thus improved, they were added at Grafton to the Mississippi river in the proportion of 1 to 7, at the time they reached the Missouri river, the intake at the chain of rocks, they would be still more changed, wouldn't they?

A. You mean as far as nitrification is concerned, or in all conditions?

Q. Yes?

A. They would be changed as far as nitrification is concerned probably. I suppose that process might keep on in the Mississippi river to some extent.

Q. They would also be very vastly changed by dilution, would they not, and mixture with the Mississippi river water?

A. They would be changed by dilution, yes.

Q. And the character of the water into which they were injected at Grafton by the Illinois river, would be very vastly modified by influence with the water of the Mississippi river?

A. After the mixture of the water of the Mississippi river the resulting water would no doubt be quite different from that in the Illinois river.

Q. Are either one of these samples positively bad and unsafe for drinking purposes?

A. I couldn't say from these analyses. I could not definitely say from these analyses. 3565

Q. Would either one of these analyses, existing in water which is used for drinking purposes, produce disease?

A. I couldn't say from these analyses.

Q. Would either one of them produce typhoid fever?

A. I couldn't say from these analyses.

RE-CROSS-EXAMINATION, by Mr. Todd.

Q. Mr. Whipple, you answered in reply to the question, if the liquids leaving the Chicago Drainage Canal at Lockport were polluted, and you answered Yes.

A. Yes, sir.

Q. What was the proportion of pollution?

A. I couldn't say that definitely.

Q. Polluted in what way?

A. Polluted by the sewage of Chicago.

Q. How do you know that it was polluted with the sewage of Chicago?

A. I have seen the Chicago river entering the Chicago Drainage Canal and I have seen some of the sewers of Chicago entering the Chicago river, and I believe it to be polluted with the sewage of Chicago.

Q. I am speaking of your own knowledge, now, Mr. 3566 Whipple, and if in my questions you will confine yourself to your personal knowledge we will get along much faster.

A. Yes, sir.

Q. Do you know what proportion of dilution the sewage of Chicago bears to the 300,000 cubic feet per minute that passes over the Bear Trap Dam?

A. I couldn't tell you exactly, but I know what the limit dilution prescribed by law is.

Q. What are they?

A. 20,000 cubic feet per minute of lake water to the sewage of each 100,000 inhabitants of the Sanitary District of Chicago.

JUDGE SPRINGER: Isn't that per second instead of per minute?

A. Per minute.

Q. That would make a difference then of sixty times, if it is per minute?

A. Yes, sir.

MR. TODD: And when you stated that you based it upon your knowledge of the conditions as enunciated in the law?

A. I have read the law, yes, sir.

Q. Now, in the 300,000 cubic feet of water that is passing over the Bear Trap Dam at present, what proportion of that is sewage, and what proportion of it is Lake Michigan water?

A. I couldn't say exactly, for I don't know the exact 3567 volume of the sewage which enters the canal.

Q. Have you any knowledge of the amount of sewage that enters the drainage canal, as distinct from lake water?

A. I believe it to be true that the sewage of approximately a million and a half people enters the Chicago drainage canal. I cannot give you the exact figures, but I believe that to be true.

Q. What is the amount of sewage known as feces and urine that is ejected from each individual in a period of twenty-four hours?

A. Speaking generally the amount of urine is about a quart and a half, more or less. I do not recollect at this moment, the exact amount of feces.

Q. In ounces, how many would you say?

A. I don't remember.

Q. Where you stated 88 per cent. in your answer, will you tell me what that 88 per cent. meant; I don't recall it right now, and I simply want to get it for a question that I want to ask you?

A. In the question to which you refer, I think it was stated that the flow from the Chicago Drainage Canal was 300,000 cubic feet per minute, and it was assumed that the minimum of that flow at Peoria was 40,000 cubic feet per minute; that 3568 is the minumum total of 340,000 cubic feet per minute, and I meant that 300,000 cubic feet per minute coming from the drainage canal was about 88 per cent. of this total.

Q. Of the total of what?

A. Of the combined flow.

Q. At Peoria?

A. At this point, Peoria, under the conditions assumed.

Q. What proportion of that 88 per cent. is sewage, and what proportion is lake Michigan water?

A. I couldn't tell you exactly, but if we assume—

Q. I don't want any assumptions; I want actual knowledge.

A. I was going to give you or to express an answer, giving you as good a result as I could.

Q. Have you any accurate data on the question?

MR. JEFFRIES: Let the witness answer. Go back to your answer to the other question that you started on and finish it.

A. (Continuing) If the 300,000 cubic feet per minute flowing from the Chicago drainage canal receives the sewage of Chicago, according to the dilution prescribed by law, then the combined flow at Peoria, obtained by adding 300,000 cubic feet per minute from the canal and 100,000 cubic feet per minute representing the flow of the stream, we should find that the mixture contained the sewage of Chicago approximately to the amount of 23,000 cubic feet per minute for each 100,000 3569 inhabitants; that is by dilution the ratio was increased from 20,000 cubic feet per minute for each 100,000 inhabitants, to 23,000 cubic feet per minute. I do not think I can express my answer in any closer terms than that.

MR. TODD: Have you finished?

A. Yes, sir.

MR. TODD: I move to strike out the answer as not responsive to my question.

Q. What proportion of that 88 per cent. is sewage and what proportion is Lake Michigan water?

A. I couldn't tell you the exact proportions of Lake Michigan sewage in the water, no, sir.

Q. Can you give me any actual personal knowledge free from any assumptions that you might make?

A. No, sir; I cannot; unless I allow a fair quantity of sewage for each inhabitant of the City of Chicago.

Q. Do you know what the fecal and urine discharge per capita is in the City of Chicago?

A. Not definitely, but such calculations can be made.

Q. Do you know of your own knowledge, independent of any assumptions, what the fecal and urine discharge per capita is in the City of Chicago?

A. Not such that I could express it mathematically.

Q. Now, in the samples known as 1, 2 and 3 that you
3570 have testified about; did those samples indicate sewage
pollution?

A. I couldn't say definitely from these samples without regard to anything else.

Q. What other elements would you have to know as to whether those samples are sewage polluted without assuming that they are sewage polluted?

A. I should want to know the character of the water, the character of the so-called pure water, with which the sewage was supposed to be mixed. As I stated the other day—

Q. May I ask you to let my question be read to you, as I see you do not understand it?

A. Yes, sir.

Q. (Question repeated.)

A. I need no other elements, but I should naturally desire to know something about the bacteria present, to note the abundance of bacillus coli, the color of the water, the odor of the water may be of some assistance also, etc., but then, with these additional quantities I might not be able to tell whether these were or were not sewage polluted, if I didn't know certain other things.

Q. Then if those samples in themselves did not indicate sewage contamination, how are you able to institute a comparison between those samples in regard to the diluted sewage contained in each?

3571 A. Because they were assumed to be a mixture of pure water and sewage, and I was simply asked to compare one with the others.

Q. What is sewage chemically speaking?

A. Do you mean as shown by the elements of water analyses?

Q. (Question repeated.)

A. It consists of organic and mineral matter in water, some of which may be in solution, and some of which may be in suspension; some of the organic matter may be lifeless and some of it may contain or be made up of living organisms.

Q. Is sewage made up of what is known as hydrogenous compounds?

A. Partly.

Q. What are the hydrogenous compounds of the sewage of man?

A. In the compounds are contained, hydrogen, nitrogen, oxygen and carbon perhaps.

Q. Have they any names?

A. A great many names.

Q. What are they?

A. The urea, for instance. Then we have the marsh gas and many other very complex compounds, cellulose, and a great many such substances, I cannot name them all at this moment.

Q. How does the sewage from man differ from the sewage of slaughterhouses?

A. I couldn't say exactly from a chemical standpoint.

3572 Q. Which sewage will purify itself or oxidize quicker, the sewage discharge of man or the sewage discharge of slaughterhouses in water?

A. I couldn't say exactly, using the word "purification" in a general sense.

Q. Using it in a chemical sense, could you say?

A. In the sense of destruction of organic matter do I understand?

Q. Yes?

A. I couldn't say exactly.

Q. If three samples of water, such as you have testified to, should be presented to you and your analyses should disclose ingredients such as have been assumed to exist in these three separate samples and your opinion was asked as to whether those samples were sewage polluted or not, what answer would you make?

A. I could not be able to tell definitely from these. I could give some idea possibly as to the relative probability, but I could not give what I would consider a definite answer from these analyses.

Q. Could you give any scientific opinion based upon these analyses alone?

A. Based upon any one of these analyses alone, without considering anything else than the figures here shown,
3573 and without knowing the source from which they came,
I couldn't state definitely that these were samples of sewage pollution if I knew absolutely nothing about them aside from these figures.

Q. Is there anything in either one of those samples which would indicate that if a person took into his system water similar, chemically similar to either one of those samples, that he would contract typhoid fever?

A. No, sir.

Q. Is there anything connected with the analyses of these three samples that would indicate typhoid fever?

A. No, sir.

Q. What experience have you had with Asiatic cholera?

A. I have studied the organism in the laboratory. I have had no practical experience with the disease.

Q. Have you ever seen a case of Asiatic cholera?

A. No, sir.

Q. Do you know how long the germ of Asiatic cholera would live in running waters?

A. I don't know definitely, no, sir.

Q. Assume that there should be an epidemic of smallpox in Chicago, under existing conditions, is it possible that the germs of that disease would find their way to the intake of the water tower of St. Louis?

3574 A. I don't know anything about the germs of smallpox;
I cannot answer your question, but so far as scientific

evidence goes, I know of no reason for believing that smallpox is transmitted by water, even though the germ of smallpox may not be known to science.

Q. The same would be true of scarlet fever, wouldn't it?

A. Practically so, although some scientists claim they know more about the germ of scarlet fever than they do about the germ of smallpox, but practically true as far as being a water borne germ, yes.

Q. Is it a fact that the germ of smallpox has been discovered?

A. I know that a scientist has recently claimed that he has discovered the cause of smallpox; I don't think that has generally been accepted by scientists, although it may be true.

Q. When chlorine is found in water in the proportion of 6, 16 and 26 as indicated in the samples 1. 2 and 3, are the samples containing the largest amount of chlorine, the 6, 16 or 26?

A. Well, the one which contains the 26; the sample which contains the 26 parts of chlorine contains the largest amount, larger than those which contain 16 or 6.

Q. That is the way that quantity or amount of chlorine is expressed in that way, is it?

A. Expressed in parts per million.

Q. Is sample No. 3 the one that contains 26?

3575 A. Yes, according to my memoranda.

Q. When the assumption was made that sample No. 1 would cause typhoid fever in Chicago, was there anything in the sample indicated that such a condition would obtain?

A. No, sir.

Q. Then the conclusion in the assumption that samples 2 and 3 would cause more typhoid than No. 1 is purely an assumption based upon no scientific knowledge in connection with the three samples, collectively or separately, is it?

A. It was an assumption that sample No. 1 was the cause of typhoid fever. It is a further assumption that this was a mixture of pure water and sewage. It is a reasonable assumption that the typhoid fever was caused by that portion of the sample which was sewage and not that portion which was pure water, and in such a case, it is reasonable or it may be reasonable to infer that samples 2 and 3 would be more likely to cause typhoid fever because of containing a larger proportion of sewage than the first one.

Q. Do samples numbered 2 and 3 contain more sewage than No. 1 as evidenced by the analysis that is before you?

A. On the given assumptions that these three samples were all mixtures of pure water and sewage.

Q. Well, independent of any assumption, taking the samples as they appear.

3576 MR. JEFFRIES: Let the witness answer the question.

MR. TODD: I thought he was through.

A. I had finished.

(Question repeated.)

A. Independent of any assumption, I could not say from samples 2 and 3 that they contained sewage.

Q. In the hypothetical question put to you the words "less valuable as drinking water" were employed, to which you remember I objected?

A. Yes, sir.

Q. What scientific significance, do the words "less valuable" have in regard to drinking water?

A. I use "less valuable" speaking from a sanitary standpoint; of course water may be less valuable for other reasons, but the question of sanitary value, the sanitary condition of the water enters into the value of that water for drinking purposes.

Q. Assume that the water at Grafton, in 1899, prior to the opening of the drainage canal was condemned by the city health department of the city of St. Louis, after examination and analysis by the city chemist as being not potable and not fit for use, would the entrance of the drainage canal into that water, render that water less valuable for drinking purposes?

A. I think it would.

3577 Q. Then what value would you attach to water for drinking purposes if it was condemned as non-potable water and dangerous to the public heath prior to the opening of the drainage canal?

A. I would say that it was less valuable. It is a case of relative conditions.

Q. What value would you attach to a water which had been condemned as being sewage polluted?

A. That would depend upon how much it was sewage polluted.

Q. Polluted to the extent that the City Physician of St. Louis after chemical analysis of the waters, denominated it unfit for drinking purposes, and dangerous to public health, what value would you attribute to water of that character?

A. If it were true that it were absolutely unfit for drinking purposes I should consider that from a sanitary standpoint it had a very low value.

Q. Would you give to that kind of water any value as drinking water?

A. Yes, if I couldn't get any other.

Q. Assuming that the city of St. Louis is so situated that it could get other water, and that the water of Grafton in the Illinois river by the analyses of the city chemist in 1899 was condemned and pronounced dangerous to the public health of the city of St. Louis, what value would you give to that water?

3578 A. If it were really dangerous to health I should give it a low value.

Q. How low would you put that value?

A. That would depend upon how much it was polluted; I couldn't state that in mathematical terms.

Q. As a sanitarian, would you give any value to water for drinking purposes, which has been by the analyses condemned as dangerous to public health?

A. If I knew that every glass of water which was take from that source—I shouldn't give that glass of water any sanitary value. and a larger number of glasses of water that would be necessary to be drunk in order to produce the disease why the more value it would have.

Q. How many glasses of water at the present time of the city water supply, is drunk before disease is produced?

A. I couldn't say.

Q. What value do you give to the present water of the City of St. Louis?

A. I cannot express that in definite terms. I think that the water certainly has a value.

Q. Suppose that public statistics should show that less

than one person in over 500 is sick in the city of St. Louis and less than 1 in 2,000 gets typhoid fever a year, and during the year 600,000 people drink on an average a pint of water
3579 a day, what value would you give to the water of St. Louis?

A. The range that you have stated, is so wide that it would be pretty difficult to give an exact opinion.

Q. What is the par value of drinking water in per centage, according to the use of the word "value" in the hypothetical question that you answered, of Mr. Jeffries?

A. I don't think that can be stated in definite terms, I should think that the par value would be water which would have from a sanitary standpoint no injurious effect on the public health.

Q. Do you know whether the water that entered the St. Louis intake prior to 1900 was such a water as to have no effect upon the public health?

A. I couldn't say that it did not have an effect upon the public health.

Q. Assuming that bulletins from the board of health, almost daily and monthly throughout the year, advised the citizens to boil the water, what would your opinion be as to the value of the water of St. Louis, prior to the opening of the drainage canal, as it affected the public health?

A. I don't think I could say just from the bulletins. It would depend upon who made the bulletins and what grounds he had for making them.

Q. Assume that he made examinations according to the established line of chemical analyses, and according to the
3580 methods used in exhibit 1 for identification, and arrived at the conclusion that the water was dangerous to public health, and requested that the water be boiled, what value as a sanitarian would you give to that water?

A. I don't think I could judge from that fact alone.

Q. Assume that since the opening of the drainage canal, the public health office by the same method of analyses has advised that the water be boiled before consumption, what value would you give to the water now?

A. As a sanitarian I couldn't give a value to the water simply from public bulletins concerning the water.

Q. What are the conditions of the water today as differing from the water prior to 1900, at the St. Louis intake?

A. As I understand it—

Q. From your actual knowledge, then, independent of public bulletins?

A. As I understand it, there is a greater possibility today of the water supply of the city of St. Louis at the intake being polluted than there was before January 17th, 1900, by reason of the discharge of the sewage of Chicago through the Chicago Drainage Canal.

Q. Has that probability been scientifically demonstrated?

A. I believe so, within the bounds of scientific judgment. It has not been chemically demonstrated.

3581 Q. Has it been chemically demonstrated?

A. I have no information that leads me to believe that it has been chemically demonstrated, excepting that I understand that certain results of the analyses in general show slight increases in the organic matter, etc., indicating of itself, but not proved.

Q. Do these indications rise to the dignity of proof?

A. No sir, I do not consider that they do.

Q. Has the demonstration scientifically been made that the waters that enter the intake tower today, are more injurious to public health than they were prior to 1900?

A. I don't believe it has been chemically or scientifically proved, but I believe that scientific judgment leads us to believe that such is the case.

Q. When scientific demonstration fails to establish a fact then the so-called scientific judgment does not differ from the judgment of a man who is not scientifically advised, drawing his inference from the same conclusion?

A. Where an absolute scientific demonstration is impossible the next best thing to my mind is a scientific judgment.

Q. Well, can a judgment be scientific when the facts upon which that judgment is predicated, are incapable of scientific demonstration?

A. No sir.

ADJOURNED until 2:00 P. M. same day, May 18, 1903.

3582 Southern Hotel, St. Louis, Missouri. 2:30 P. M., Monday, May 18th, 1903. Parties met pursuant to adjournment. Present, the Commissioner and same counsel representing the respective parties.

GEORGE C. WHIPPLE,

resumed the stand for further re-cross-examination by Judge Springer, and testified as follows:

Q. Mr. Whipple, calling your attention to the question put to you this morning by General Crow, and your answer thereto, in reference to the possibility of germs of Asiatic cholera coming from the City of Chicago to the City of St. Louis, or to the St. Louis intake, did you take into consideration any facts in regard to the longevity of such germs?

A. I didn't take any facts, especially in mind, when I spoke, but I believe from what I know of the subject that the germ of cholera will continue to live in water for a considerable period, though probably like the germ of typhoid fever, in diminishing numbers.

Q. In diminishing numbers?

A. In diminishing numbers as time goes on.

3583 Q. Is it not the opinion of scientists, and do not bacteriological examinations of water show that the bacillus of Asiatic cholera is of very short duration?

A. I would not say that that is the generally accepted opinion. If I were comparing the two germs, typhoid and Asiatic cholera bacillus I should say that from what I know, that it was quite possible that the germ of Asiatic cholera might not be as hardy as the germ of typhoid fever, but I do not believe one can say that it will not live for a considerable period in water. In fact I believe that it will.

Q. Do you know of any instance where a microscopical examination of natural water has revealed the fact that the germ of Asiatic cholera survived as long as ten days in unsterilized water?

A. I do not recollect at this moment; I know that there have been experiments made upon that subject, but I do not remember just how long they did survive.

Q. You cannot point then to any instance recorded in authentic works, upon this subject, in which bacterial examinations have shown a longevity of Asiatic cholera germs equal to ten days?

A. I don't think of any special experiments at this time, that shows that, no sir.

Q. Doesn't the effect of sunlight upon these Asiatic cholera germs tend to reduce their virulence and longevity in a very marked manner?

3584 A. I should say, speaking in general, that sunlight would tend to reduce the longevity, but I cannot say quite as much as to the virulence, but it is possible that it might act in the same way with virulence. also as a rule. Speaking in general terms, sunlight is inimical to bacterial life.

Q. Does not the virulence of the germ of Asiatic cholera decrease very rapidly in un-sterilized water, and in sunshine?

A. I am inclined to think that the virulence would decrease, but how rapidly, I cannot say.

Q. Do you know of instances where peritoneal injections of the Asiatic cholera germs in lower animals would produce an injurious result?

A. I think so.

Q. After the length of three or four days from the time of culture?

A. I don't recollect any special experiments, where the time interval was taken into consideration. I have read more or less on the subject, but I do not recall at this moment, just the point that you speak of.

Q. If it should appear from investigations that have already been had or those which you should make hereafter, that the germs of Asiatic cholera do not survive in unsterilized water for a greater period than five days or ten days, you may put the limit if you please, then your answer this morn-
3585 ing that they might get here would be a mistake, would
it not?

A. If it could be proven to me that such germs would not live in natural waters under conditions existing, my conclusion might be changed, but just as in the case of typhoid fever, I am not sure at all that the conditions existing in a laboratory experiment would be comparable to those which would exist in running streams.

Q. And if the conditions in a laboratory experiment were kept as nearly equal as possible to those which would prevail in the running water, and if under those conditions the examination should show a vitality of less than ten days and a constantly decreasing virulence during those days, what would you say then as to the probability of the germs of Asiatic cholera coming from Chicago into the St. Louis intake, and if they should come, as to the probable virulence they would have?

A. In so far as the results of certain experiments were conclusive in showing that the cholera germ could not live in natural waters, I should lessen my opinion as to the probability of their surviving from Chicago to St. Louis, but I question whether or not it would be possible. I question whether or not it would be possible in a laboratory, to duplicate the conditions.

Q. Is that your answer?

A. I think I have answered the question.

3586 Q. Isn't it the object of all these examinations in a laboratory to duplicate the conditions which exist naturally, as nearly as possible in order to reach a result that is of some value?

A. I think it is. In the absence of our ability to exactly duplicate the conditions, we do the best thing we can to duplicate them; in so far as we are successful, these results may be considered as having value.

Q. In so far then as you can duplicate any one of these in a laboratory experiment, duplicate the conditions which exist in the natural water, in so far are your conclusions of value?

A. Yes sir, and of course we must also duplicate the conditions in regard to the organisms themselves used in experiments and those which were introduced in the water.

Q. And that therefore, the further you depart in your laboratory experiment from the conditions which prevail in the natural water, the further removed are your experiments from any practical utility?

A. Yes sir.

G. C. WHIPPLE.

Adjourned until 10 A. M. Tuesday, May 19, 1903.

Southern Hotel, St. Louis, Missouri.
3587 10:00 A. M., Tuesday, May 19, 1903.
Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

WILLIAM THOMPSON SEDGWICK,

called as a witness in behalf of the complainant, being first duly sworn by the Commissioner, was examined in chief by Attorney General Crow, and testified as follows:

Q. Please give the stenographers your name, address and occupation.

A. William Thompson Sedgwick; residence, Boston Massachusetts.

Q. Professor, where were you educated?

A. I was graduated at Sheffield Scientific School at Yale in 1877; studied for the greater part of two years in the Yale Medical School; taught physiological chemistry at Yale for one year; became fellow, assistant, and associate of Johns Hopkins University, Baltimore; proceeded to Boston in 1883, and have since that time been assistant professor, associate professor, and professor in the Massachusetts Institute of Technology,
3588 In Boston. I received the degree of Doctor of Philosophy
at Johns Hopkins in 1881. I am not a physician. I have studied in a medical school but I have no medical degree. Shall I give some of my positions?

Q. Yes sir.

A. I served as biologist to the State Board of Health of Massachusetts from 1888 to 1896; I am a member of the American Academy of Arts and Sciences; Massachusetts Association Boards of Health; New England Waterworks Association; Society of American Bacteriologists; American Society of Naturalists; American Public Health Association; Member of the Advisory Board of the Hygienic Laboratory of the United States Public Health and Marine Hospital Service; Past President of the American Society of Naturalists; and of the Society of American Bacteriologists. I may say that I have been employed by various cities and towns as an expert in water supply or

sewage disposal, especially by Burlington, Vermont, Pittsburg, Pennsylvania, and possibly one or two more that I do not now remember. Yes, Lowell, Massachusetts. I am the author of a text book on General Biology, and of a treatise on the Principles of Sanitary Science and the Public Health published last year. I have made numerous reports and investigations of epidemics of typhoid fever for the State Board of Health of Massachusetts, a report on typhoid fever in Pittsburg in 1898, and have published numerous papers on water supply, water purification, sewage purification and so on besides a paper on typhoid
3589 fever in Chicago, published in 1892, with Mr. Allen Hazen, the well known engineer. I trust that that is sufficient.

Q. You are a biologist?

A. Yes sir.

Q. What does that term imply scientifically?

A. It implies work upon living things, which may be anything, from man to microbes. It is a very general term and of course I do not pretend to be an expert in all its departments.

Q. You are now Professor of Biology in the Boston Institute?

A. Yes sir.

Q. Massachusetts institute of technology?

A. Yes sir.

Q. You are an epidemiologist?

A. Yes sir.

Q. What does that term imply?

A. That implies a study of—or ought to imply and does imply I hope, an expert knowledge of epidemics, their origin, their characteristics, their scope, and everything else relating to them.

Q. Well have you made that branch of sanitary science, as related to the American cities and towns, and the American public, a study?

A. I have sir. It so happened that in my work for the State Board of Health of Massachusetts, I was confronted in
3590 1890 with one of the most serious epidemics of typhoid fever that we have ever had in this country, at Lowell, Massachusetts, and acting partly for the Water Board of Lowell, and partly for the State Board of Health of Massachusetts, or

jointly I should rather say for the two, I made a very careful study of that epidemic that gave me a certain reputation; which led me to be called in for the purpose of investigation of other epidemics, and as just at that time my attention was drawn to the great epidemic of typhoid fever in Chicago which threatened the welfare of the people who should visit the World's Fair, I made an investigation of the facts in that case, and together with Mr. Hazen, published the paper that I have already referred to.

Q. You are also a bacteriologist, are you?

A. Yes sir.

Q. You have had practical experience in that?

A. I have taught bacteriology and have had practical experience in that line.

Q. Did you ever analyze any of the waters of Lake Michigan?

A. No sir,—or, I think I did once or twice, but not to any great extent.

Q. Bacteriologically you have analyzed the waters of other towns and cities?

A. Of some other towns and cities.

3591 Q. Mention some of them?

A. Especially of Lowell and—

Q. Duluth?

A. Duluth, Pittsburg—no, not Pittsburg, Duluth; Newburyport, Massachusetts; Holyoke, Massachusetts, and Burlington, Vermont. Possibly some others, but mainly Massachusetts cities and towns.

Q. In the preparation of the paper you mentioned, on typhoid fever in Chicago, in 1892, did you have occasion to investigate the physical conditions and sanitary conditions of the City of Chicago with reference to water supply, sewerage and sewer out-falls at that time?

A. In a general way I did. I was visiting the World's Fair—I was visiting the Exposition when it was being got ready for the next year, having charge of the installation of certain exhibits there, and I spent quite a little time in going about the city and familiarizing myself with the local conditions.

Q. Well state generally what you found with reference to the sanitary condition of that city, as to the water supply and as to the sewage and its relation to the water supply and the effect thereof on the health from the standpoint of typhoid fever.

A. I came to the conclusion, mainly from a study of the
3592 typhoid fever statistics and the general arrangements of
sewerage and water supply, that the water supply of the City of Chicago at that time was seriously polluted with sewage,—so seriously that the city was then suffering from one of the worst epidemics that ever afflicted any American city and that this pollution was derived from typhoid cases in the city of Chicago which contributed their sewage to the sewers of the city, and that those emptied their sewage either into the Chicago river or into the lake, and in that way gave occasion for the germs of the disease to get into the "cribs," or the intakes of the water supply.

Q. Did you or did you not have occasion at that time to investigate the physical condition and the sanitary condition of the Chicago River and its branches?

A. I made no very thorough investigation; I simply walked along the river at various points and noticed its condition, which was obvious to the eyes and nose.

Q. And was that condition polluted or un-polluted at that time?

A. It was grossly polluted.

Q. Now what is the source and character of the Chicago city water supply?

A. The public water supply of the City of Chicago is and
for many years has been derived from Lake Michigan
3593 through a series of intakes called "cribs," which lie at
different distances from the shore.

Q. In front of the city?

A. Along the lake front; and which were supposed originally to obtain pure water from the lake, but which as the population has increased, have naturally received more and more contamination from the sewage of the city itself.

Q. What becomes of that portion of the Chicago city water supply which is used for domestic purposes?

A. That is of course passed through the houses of the people and through the bodies of some of them, and poured into the sewers, more or less polluted.

MR. TODD: Read that question.

(Question read).

MR. TODD: Is that now, or in previous times?

GENERAL CROW: You can consider it in either way; as it is meant to cover both periods of time, both in the past and now I suppose that it results the same.

Q. Did you finish answering the question?

A. Possibly not, as it has been interrupted.

GENERAL CROW: Read the answer.

(Answer read).

Q. Now are the Chicago sewers built on the separate or
3594 combined plan; that is, do street washings, rain-falls and
surface water enter the sewers?

A. They are built, I believe upon the combined plan.

Q. Now what is the effect of that on the flow and speed of flow in the sewers themselves?

A. It means of course that street washings and storm water find their way into the sewers, and greatly accelerate the flow in the sewers, at the same time diluting the sewage somewhat.

Q. And what is the effect of that as to the time-factor of removing the sewage as it comes from the house connections into the place where the out-falls of the sewers empty?

A. Well, of course the effect during the year, or broadly speaking, is that it very much accelerates the flow and shortens the time spent in the sewers.

Q. Then in a city where the sewers are built on a separate plan, and storm waters and the street washings and surface waters are cared for otherwise than directly through the sewers, would the sewage matter pass from the house connections as rapidly to the sewer out-falls as in a city where the sewers are used on the combined plan?

A. No sir, not on the average. Of course during storms—

Q. Other conditions being equal?

A. Yes, other conditions being equal.

Q. What else besides domestic waste, including urine and
3595 fecal matter, enters the Chicago sewers?

A. As I have just said, of course street washings would find their way in, and any material that human beings are likely to add to sewers might find their way thither; the washings of stables, the discharge of waste of breweries, of manufacturing industries, of bake-shops, butcher-shops; the material from hospitals;—any or all of the filthy material of a population which seeks to get rid of it, and which material is not carried off in any other way, as garbage or any other material.

Q. How much sewage matter do you estimate is discharged daily into the Chicago sewers?

A. I have not made any careful estimate of that, but I should say several hundred tons.

Q. Into what are the contents of the Chicago sewers discharged?

A. Into what?

Q. Yes sir?

A. They are discharged partly into the Chicago river and partly into the Lake itself.

Q. Do you know what proportion of the population of Chicago and the Sanitary District discharges sewage into Lake Michigan roughly estimated?

A. I think it is something over a quarter of a million of inhabitants.

3596 Q. Into Lake Michigan?

A. Into Lake Michigan.

Q. Now where does the remainder of the sewage of that population discharge?

A. That is discharged into the Chicago River, and from that into the drainage canal.

Q. What is the effect in general terms, of the discharge of sewage of the population sewering into Lake Michigan, upon the character of Lake Michigan water both in the vicinity of the mouth of the Chicago River and the intake cribs of the municipal water system?

JUDGE SPRINGER: Is that question relating to the present time or to the time when Professor Hazen made his investigation?

GENERAL CROW: It relates to the present time; what is the effect; not what was the effect, is the terms of the question.

A. It tends to pollute those waters.

Q. Are you acquainted, generally speaking, with the conditions prevailing in the Chicago River, Chicago Drainage Canal, and the water courses through which the Chicago sewage flows, from Lockport to the Mississippi river, and also those general features on the upper Mississippi and Missouri rivers which affect the sanitary quality of the St. Louis water supply, and the waters of the Mississippi River below the mouth of the Illinois, that are or may be used by the inhabitants of the State of Missouri for drinking purposes?

3597 A. Yes sir.

Q. Now Mr. Sedgwick, speaking as an expert of water supplies, do you recognize any difference between the pollution of water and infection of water? If so, state what it is?

A. I do recognize a difference between mere pollution and infection,—or what I might call infectious pollution,—somewhat as follows: I understand by pollution alone, a condition in which a water contains organic matters, or even filth, free from the germs of specific diseases; and I understand by infected water or an infectious pollution of water, or an infectious contamination of water, a condition in which, either with the same or more, or less pollution the germs of specific diseases are present; so that a water may be polluted, from my point of view, but not infected, or it may be infected and yet to the ordinary eye not polluted.

Q. Then do you recognize the difference between the effect of pollution in water that will produce an obnoxious condition of the same and the effect of pollution of water that will produce danger to health?

A. I do, decidedly. And the water may be so polluted as to be unattractive or objectionable otherwise than from the disease-producing standpoint.

Q. Well, is water that is polluted by infectious pollution a dangerous water?

3598 A. I don't think I got the question?

Q. Is water contaminated by infectious pollution a dangerous water?

A. Yes sir.

Q. Professor, I will ask you to state whether or not dilution will destroy or eliminate infectious pollution or matter in waters?

A. No sir. Mere dilution, I understand?

Q. Yes.

A. Mere dilution.

Q. Now Professor, on the basis of dilution alone, do you consider that the sewage from the Chicago Sanitary District as it reaches the Illinois river above Peoria, is at all times rendered pure and safe for domestic use?

A. No sir.

Q. Will running water absolutely purify itself so as to be free from pathogenic bacteria that may have been placed therein?

A. That is a large question, sir. I shall have to answer that in a somewhat lengthy way, I am afraid.

In this whole matter of self-purification of streams we have today very different ideas from what we had twenty or thirty years ago. In trying to answer the question specifically and closely—if I tried to answer it specifically and closely,
3599 I should have to say that running water under some conditions might conceivably, very largely, and possibly even altogether, purify itself from infectious germs, but those conditions would have to be very unusual and so unusual as to be practically theoretical, or virtually theoretical. It was formerly believed by experts that running water readily purifies itself. That belief has been altogether abandoned. Acting upon that belief, which was the best state of our knowledge twenty or thirty years ago, numerous cities and towns of the United States put in waterworks which should derive water from streams into which sewage had been poured at points above. That was the best art of the time, and engineers, chemists and sanitarians agreed about it. In the city of Pittsburgh, for example, which I have especially studied,—into the city of Pitssburgh, the water supply was introduced from the Allegheny river, with the confident belief that such sewage as might find its way into that river at points above would be effectually removed before the citizens had ac-

cess—before the water came to the citizens. That belief has been found to be erroneous. Pittsburgh suffers today with typhoid fever perhaps more than any other city of the United States,—certainly excessively. The cities on the lakes,—Niagara Falls, Buffalo, Cleveland, Detroit, Chicago, Milwaukee,
3600 Duluth, take water supplies subject, or exposed to contamination by sewage, and are today, one after another, considering at any rate the possibility of abandoning such supplies, because of the failure of the self-purification of sewage. Nevertheless, there is a large measure of self-purification of streams. There is at times, in certain streams, especially, a large measure of self purification. The subject is a complex and difficult one, and the tendency of opinion, the growth of opinion, has been to increase our distrust in the efficiency,—the efficacy of self-purification of water or sewage.

I don't know that I need to add very much to that.

Q. Well, you have written on that question in your book—

JUDGE JOHNS: I move to exclude so much of the foregoing answer as relates to the inferences and conditions named in the answer commencing with Pittsburgh and ending with Duluth, as not material to this inquiry.

Q. GENERAL CROW: You have written something on that question in your book?

A. Yes sir. Three or four years ago in studying this subject carefully, I arrived at a conclusion which I stated in a book published a year ago, before I had any expectation of any connection with this case, which gives substantially the same point of view that I have stated, but which I should be glad to read if it is proper.

3601 Q. If it is your own statement, you can read it of course, the same as you would state it.

JUDGE JOHNS: I move to exclude the answer as not responsive to the question and at any rate immaterial to any issue in this case.

Q. (Question read).

MR. TODD: I object to the question in so far as it requests the witness to read from a book published by him, on the ground that the subject about which it is supposed he is about to read is immaterial to this inquiry, and amounts only to a matter of opinion.

GENERAL CROW: Go ahead, Professor.

A. "Today we realize that this theory of purification is only half true, and that such self-purification is only partial and absolutely unreliable." (Witness reads further from book): (Principles of Sanitary Science and Public Health, Macmillian.)

"By a curious reversal of scientific opinion, we now hold that it is precisely running water which is least likely to purify itself, while stagnant or standing water, formerly looked upon with dread and suspcion, is now in much favor. The old theory was in vogue long enough to enable us to make a wonderful series of experiments, and on a stupendous scale; experiments in which whole cities confidingly used for years, sewage polluted waters, often with sad results, but results of lasting instruction to mankind. Never again so long as civilization
3602 endures, will intelligent communities acting under expert advice, repeat these sad experiments."

JUDGE JOHNS: I move to exclude the reading as immaterial and as not competent evidence.

MR. TODD: I move to exclude the answer on the ground that the facts from which this opinion is expressed in the book, have not been set forth by any statement made by the witness.

Q. GENERAL CROW: State whether or not sewage flowing directly from the out-falls of the city sewer, will effect the value for drinking purposes of a running stream of water?

A. That is flowing into the stream, of course?

Q. Yes sir.

A. Certainly; it lowers that value of course.

Q. State whether or not the sewage from a district as large as the Sanitary District of Chicago would affect the value for drinking purposes of a stream as large as the Drainage Canal and as large as the drainage canal and the Desplaines River and Illinois Rivers combined, and if so, in what manner?

A. Yes sir, the mere introduction of sewage into a stream at once creates suspicion as to the—at once throws suspicion upon the character of that stream, and unless it can be shown that that sewage has been effectually removed by purification, the value of that stream is distinctly lowered.

Q. Please state your opinion as an expert on water sup-
3603 plies for cities and towns as to whether or not the waters of the Mississippi River west of the center of the main channel of said river below the mouth of the Illnois River and down to the intake tower of the St. Louis Waterworks at the chain of rocks, is less valuable for drinking purposes and more liable to carry water-borne diseases such as typhoid fever and cholera, now than it was before the sewage from the Sanitary District of Chicago was run into the Drainage Canal and through it into the Illinois river?

JUDGE SPRINGER: I object to the question for the reason that it does not indicate whether the time fixed was the time at which the present drainage canal was opened, or whether it relates to the time previous to that when a certain amount of sewage of Chicago was dumped into the Drainage Canal.

GENERAL CROW: I refer to the drainage canal as distinguished from the Illinois and Michigan Canal.

JUDGE SPRINGER: I simply want to know what the dividing line is.

GENERAL CROW: I want to know whether or not you are going to require that all the way through this case we put the name of the drainage canal technically, into the record?

JUDGE SPRINGER: I want the witness to understand as to the time at which this line is drawn.

THE WITNESS: I understand it to refer to today, sir.

3604 JUDGE SPRINGER: I mean the time fixed by the question was since the opening of the drainage canal.

THE WITNESS: The time fixed by the question was since the opening of the drainage canal.

GENERAL CROW: It covers the period from the 17th of January 1900, to the present time.

JUDGE SPRINGER: That is all right; I simply want to know whether—

GENERAL CROW: Do you enter an objection here because I do not put in the technical name of the drainage canal?

JUDGE SPRINGER: No, I withdraw my objection now that you have stated what you mean—that you mean the drainage canal.

GENERAL CROW: I mean the Chicago Drainage Canal. If I had meant the Illinois and Michigan Canal I would have said so.

A. I consider it decidely less valuable.

Q. State whether or not the increase of the volume of water in a stream will increase the speed of the current?

A. Ordinarily it will.

Q. State if you know what is the increase in the volume of water in the Ilinois river by reason of the flowing of the waters of the drainage canal into said river,—in a general way?

A. About 5,000 cubic feet per second.

Q. Well, relative to the quantity of water in the Illinois river, do you know what proportion the added volume
3605 from the drainage canal would bear to the waters of the Illinois?

A. At the period of lowest flow it might perhaps, be as high as five-sixths; with the ordinary flow it would of course be less than that. I have only general knowledge of the hydraulics of the river.

Q. State whether or not an increase in the speed of the current of the Illinois river by reason of the added volume of the water of the drainage canal would effect the amount of sedimentation that might otherwise occur in the Illinois river, and if it does affect it, how and in what manner?

A. The addition of such a volume of liquid as passes through the drainage canal must materially,—must often materially, quicken the flow of the Illinois river; it must therefore hinder effective sedimentation, and thus by shortening the time required for infectious germs to pass through the river, and by interfering with their detention, aggravate the danger of their arrival at the mouth of the river. I should like to say right here, that the time allowed in all these matters is very important, so that any quickening of the flow is a grave consideration. It is not so much distance as time which is the basis of self-purification of streams.

Q. What effect, if any, Professor, would the increase in the speed of the current of the Illinois river have upon the

3606 time within which sewage from Joliet, Peoria and other towns on the Illinois river might be removed into the waters of the Mississipi, as compared with the conditions that existed and the time it might have taken before the added volume of water from the drainage canal was poured into the waters of the Illinois?

A. I will ask you to read that.

Q. (Question read).

A. It would shorten the time.

Q. For what reason?

A. Because by increasing the flow, by quickening the flow, sewage or infectious pollution from Peoria and the lower points might arrive more quickly at the mouth of the Illinois, and mingle with the waters of the Mississippi.

Q. Professor, if water is made more clear and less turbid than it was before by an added volume of water being placed therein will such bacteria as typhoid have more or less of a tendency to go down to the bottom of the stream than they had prior to the water being rendered less turbid?

A. The clearer the water, the other things being equal, the clearer the water, the slower the rate of sedimentation. The more turbid the water, the more rapid and the more effective the sedimentation, so that the addition of clear water to turbid water, as a rule, tends to postpone and delay sedimentation.

3607 Q. Professor, if an increase be made in the speed of the current of the Ilinois river by the addition of the water of the Drainage Canal, would that increase in said current, have any effect in increasing or diminishing the typhoid and liability to typhoid and other water-borne diseases on the part of the inhabitants of the State of Missouri using the waters of the Mississippi river for drinking purposes, below the mouth of the Illinois river?

A. I believe that it would have an effect, and that it would increase the typhoid.

Q. Professor, does the sewage from the cities and towns, speaking from the standpoint of an expert on water supply, pollute and render unfit for drinking purposes the waters of a running stream, for the purposes of domestic use?

A. Speaking generally it does.

Q. Professor, are settling basins recognized at the present time and have they been recognized at any time as an efficient and adequate means for the purification of sewage to be discharged in a drinking water stream?

A. Do you mean settling basins alone?

Q. Yes, considering nothing else?

A. No sir.

Q. What, Professor, in your judgment, becomes of the deposited matters in the bed of a running stream?

3608 A. The deposited matters or the matters deposited in the bed of a running stream may lie there for some time, or they may be swept out by an increase in the rate of flow of the stream. If they lie there for some time, they may be more or less modified by chemical and bacterial action. If they are returned to the stream by an increase in its velocity they may be re-deposited at lower points or borne on into some other body of water.

Q. Professor, what do you say as to the longevity of the germs of typhoid fever, as a general proposition in connection with sewage polluted water?

A. Here also, our ideas have undergone some change of late years. My ideas have undergone some change. Broadly speaking, the tendency has been to come to the belief, or has been to show or to indicate, a greater and greater longevity. Laboratory experiments have sometimes indicated a short and sometimes a longer longevity. Practical experience has tended to make us believe in a greater longevity than that formerly entertained, and having reference to the conditions in the stream, the various conditions in streams, my belief is that in a sewage polluted stream the typhoid germs might live in gradually diminishing numbers for weeks or months, or even years.

3609 Q. Professor, assuming that the numbers of bacilli coli communis in the waters of the Illinois river at Grafton are at intervals no greater than the numbers contained in it before the opening of the drainage canal, do you consider for that reason that the water is at all times no more dangerous for drinking purposes than formerly?

A. I do not. I consider that even if the number of colon bacilli as shown by occasional tests, is no higher today or were no higher today than before the opening of the drainage canal, the mere fact of the addition of a vast population contributing sewage to the Illinois river, constitutes and must always constitute, an added menace to the health of persons using the water of the Illinois river at its mouth or below. And I may add that I have this opinion or I will say, for the reason, that bacteriological examinations obviously can not be made at every moment, or I will say at all times or at all seasons or hours of the day; and are at best not absolute guides as to the sanitary condition of the water. There might be times and seasons when materials would flow by, escaping analysis, and pass on to do harm to the people below.

Q. Professor, assuming that the germs of typhoid fever coming from the sewers of Chicago and passing by way of the drainage canal to Lake Peoria, might be in large numbers deposited in the bed of Lake Peoria for the period of a
3610 month, say; do you consider that typhoid germs would be entirely destroyed at the end of that time?

A. In that deposit?

Q. Yes?

A. No sir.

Q. Professor, assuming that typhoid fever germs coming from Chicago sewage are deposited in large numbers in the lakes and slack water portions of the Illinois river above Peoria, do you or do you not consider that flood conditions such as would scour the deposits from the bed of the stream, would cause the water leaving Lake Peoria, to contain at times more infectious and dangerous pollution than are at present in the diluted sewage entering the Des Plaines River at the Bear Trap Dam at the foot of the drainage canal?

A. I think at times it might.

Q. Why?

A. Because, if accumulations of typhoid germs were formed in the lakes or slack water basins of the river, these might, especially in the case of a large amount of typhoid fever in Chicago, result in the storage there of a vast number of germs, and the sudden flood, might sweep out these accumulations and actually bring it about that sometimes more typhoid fever germs should be flowing in that stream than in the drainage canal itself.

3611 Q. Has the removal of deposits of sewage matter from the bed of streams resulted in causing typhoid epidemics?

A. I know of one excellent instance in a stream, and I think there have been some in lakes; some cases of that sort in lakes, or sluggish bodies of water. The best example, undoubtedly, that we have of such an effect in a stream, and it happens to be one that was combined with the slack water lake, so that we have the double demonstration in one case, is the well known instance of typhoid fever in Detroit, resulting from the dredging of the Black River at Port Huron, which caused the carriage of detached sediment down St. Clair river, through the St. Clair Lake and into the intake of the Detroit waterworks. I think that was in 1892 if I remember right. That is probably the most striking case we have on record. It was very thoroughly investigated, and I am familiar with the data upon which the conclusions were based, and in my opinion it is a well established case, and it is the best that I know.

Q. In which a typhoid epidemic resulted from the removal of sewage deposits from the bed of a stream?

A. Yes sir.

Q. Professor, do you consider that the water of the Illinois River since the opening of the drainage canal and now, as it enters the Mississippi river, is one which may be used with safety for drinking purposes?

3612 A. No sir, I do not.

Q. Now, Professor, assuming that the only pollution of the Illinois river was that contributed to it by the Chicago Sanitary District, and having in mind the large amount of typhoid fever in said district, do you or do you not consider the effects of the time interval, dilution and sedimentation occurring between Chicago and Grafton, would be such as to render the water as it enters the Mississippi at all times free from liability of producing water-borne diseases in those who drink it?

A. Emphatically not.

Q. Why?

A. For the reason that such processes of self-purification, including sedimentation and dilution, as would take place in the Illinois river and above, to Chicago, would be, in my judgment, inadequate to insure at all times and seasons a complete removal of infectious material.

Q. Have you had any personal experience which would lead you to believe that infected water coming from the Illinois river and entering the Mississippi might become mixed with the latter in such a way as to menace the health of the inhabitants of the Missouri shore of the Mississippi river, using the Mississippi river waters for drinking purposes, at points below on the Missouri shore?

A. I think that I have had a very instructive piece of per-
3613 sonal experience bearing upon that question. In the
autumn of 1890, I was called in, as I have already stated, to investigate an epidemic of typhoid fever in the City of Lowell, Massachusetts, and after preliminary studies I was led to the conclusion that the epidemic in question was caused or had been caused, by typhoid fever infection of a small and sluggish stream,—or I might say a small and often sluggish stream,—entering the Merrimac river, a larger and much swifter stream, almost at right angles; and that such infection and water of the smaller stream had mingled with the water of the larger stream, so that at a point about three miles below the entrance of the smaller into the larger, and on the opposite side of the river, where the city of Lowell had the intake pipe of its waterworks, the infectious material arrived, and from that point was borne into the water supply, producing an epidemic of upwards of 1,000 cases of typhoid fever.

Q. Compared with the volume of water or size of the stream of the Ilinois to that of the Mississippi, what was the relative proportion to that of the Stony Brook Stream and the Merrimac River?

A. The Stony Brook Stream was much smaller in proportion to the Merrimac river than the Illinois river is to the Mississippi River. And I may add to my previous statement, that

it was possible in this case, owing to the waste of a wool
3614 scouring mill, which was upon the smaller stream, to detect for some distance below the water of the smaller stream running parallel with the larger one, but after the distance of, say a half a mile, it was no longer possible to detect the parallelism, or rather, it was no longer possible to detect the water of the smaller stream by the eye, and the two waters seemed to have become remarkably well mingled. I may further add that there was a bend below the point of exit of the small stream, so that the water of the larger stream went, so to speak, against the water of the smaller stream as it turned.

Q. From what distance up Stony Brook did this infection in the water come?

A. A very short distance.

Q. What distance down the Merrimac river did it flow in the water?

A. As I have said, as nearly as could be determined, it entered the Lowell waterworks, and produced an epidemic, three miles and a half below, but there was also reason to believe that it reached Lawrence, nine miles farther on, and began an epidemic there, which afterwards rose to extraordinary proportions, owing as I believe, partly to this infection, and partly to the very much larger infection from the city of Lowell which, I have said, is 9 miles above the intake of the Lawrence
3615 water works.

Q. You made a personal investigation and examination of the water supply and the surroundings at the time, did you?

A. I made a very thorough personal investigation of the whole subject at that time?

Q. Now, Professor, assuming such mixture as was referred to in the question asking whether or not you had any personal experience which would lead you to believe that infected water coming from the Illinois river and entering the Mississippi would become mixed with the latter so as to menace the health, of the inhabitants of the Missouri shore, using the Mississippi river water; do you or do you not consider it probable that infectious pollution would at times enter the intake of the St. Louis Waterworks at Chain of Rocks?

A. I do.

Q. Professor, have you made any study of the typhoid fever statistics of the City of St. Louis, and if so, during what period and with what result?

A. Yes. I have made a rather careful study of the typhoid fever statistics of the City of St. Louis, and with this general result: During a period of fifteen years prior to January 1st, 1900, the typhoid fever death rate in St. Louis has not in general been above that of some cities provided with water supplies considered pure, and of good repute. During the period following the removal of the intake from the lower point
3616 to the chain of rocks, the typhoid fever death rate of St.
Louis was rather remarkably good, by which I mean that it was lower than it had been, and lower for example than the death rate of the city of Boston for that same period. Beginning with the first of January, 1900, there has been a marked annual increase in the typhoid fever death rate of the City of St. Louis, so that it has during that period not only been higher than during the previous period of five years, but also higher than at any time in its own history since 1885, and very much higher than the death rate in the city of Boston, with which previously it compared very favorably. If I may give figures, I may say that the increase in typhoid fever deaths in the city of St. Louis since January 1st, 1900 as compared with the preceding fifteen years, and excluding one year,—1892,—when there was a great epidemic in St. Louis, an epidemic which was thoroughly investigated by Dr. Ravold,—has been about 26 per cent; while the increase since January 1st, 1900 in the annual mortality from typhoid fever as compared with the preceding five years, I think it was, at any rate as compared with the period between the removal of the intake to the chain of rocks, has been 73 per cent.

Q. Are you familiar with the water supply of the City of Boston, and the death rate there?

3617 A. Fairly so, yes sir.

Q. In your opinion as an expert on water supplies for cities is the water supply of Boston and the death rate there reasonably normal?

A. I consider the water supply of Boston a fair supply, I should even say a good supply. It is undergoing a period of transformation, but it ranks among the water supplies of the country as a good water supply. The typhoid fever rate of Boston is, however, higher than that of New York or London, which are about the best that we know; so that previous to January 1st, 1900, we shall say, fairly, I think, that the typhoid death rate of St. Louis, like that of Boston, was below that of most cities, possibly of all cities, certainly most cities having polluted water supplies.

Q. Of similar size?

A. And of similar size. I may add that among the biggest cities of the United States, New York has the lowest death rate from typhoid fever. Boston and St. Louis, as I have said, ran very close together until January 1st, 1900, since which time Boston has gone lower and St. Louis has increased. Philadelphia shows a much higher death rate than Boston and St. Louis if you cover a period of years, while Chicago has the worst record of all in respect to typhoid fever, and has long had. I am speaking now of long periods, not for any one year in particular,
3618 but taking long periods.

Q. Do you know the cause of the high typhoid rate in the city of Philadelphia?

JUDGE JOHNS: I object to the question as immaterial.

A. I don't know of my own knowledge, but as an expert familiar with statistics and sanitary conditions in Philadelphia, I have no doubt that the prevailing opinion among sanitarians is correct, and that it is mainly the pollution of the public water supply.

Q. Now Professor, assuming that the only pollution upon the water-shed of the Mississippi and its tributaries, above the intake of the St. Louis waterworks, was that derived from the sanitary district of Chicago, and having in mind the large amount of typhoid fever in Chicago, do you or do you not believe that infection and dangerous pollution might find its way into the water supply of the city of St. Louis?

A. May I ask you if you mean may or might, under existing conditions?

Q. Yes might under existing conditions?

A. Yes sir, I believe that it might.

Q. Now, Professor, assuming that there was no typhoid fever pollution of the waters upon the water-shed of the Mississippi river or its tributaries above the intake of the St. Louis waterworks, other than that derived from the sanitary
3619 district of Chicago, do you or do you not believe that typhoid fever germs from said district are liable to find their way into the water supply of the city of St. Louis through the intake at the chain of rocks?

A. I believe that they are liable to find their way into the intake.

Q. Why?

A. For the reason that typhoid fever having been frequently very abundant in the city of Chicago, I must start with the assumption that a very large number of typhoid germs find their way into the sewage of the city, pass through the sewers and on into the drainage canal, and subject to local conditions may, in diminished numbers, pass out of the Illinois river, mingle with the waters of the Mississippi, pass over to the other side and find their way to the intake at the chain of rocks.

Q. Now Professor, assuming that 108 barrels containing 40 gallons each of culture of the bacillus prodigiosus each cubic centimeter of the culture solution containing 1,000 million prodigiosus germs, were emptied into the Chicago drainage canal at Lemont, and further assuming that at the time of this experiment this culture was absent in Lake Michigan water and in the Illinois river and its tributaries, in the Mississippi river above Grafton, and in the Missouri river water, and further as-
3620 suming that one or more colonies of bacillus prodigiosus on several occasions were found in samples of water taken from the intake tower at the chain of rocks, what in your opinion does this show?

A. This interesting and valuable experiment, as I regard it, seems to me to show that typhoid fever germs might pass from the drainage canal, through the Illinois river and the Desplaines river, and be carried alive to the intake of the waterworks at the chain of rocks, and there enter the water supply of the city, very likely producing typhoid fever at St. Louis.

Q. Assuming that an epidemic of Asiatic cholera should occur in the city of Chicago, is it possible that the germs of that disease might find their way into the intake tower of the St. Louis waterworks at the chain of rocks, from the city of Chicago?

A. I consider it possible that they might.

ADJOURNED until 2:00 P. M., same day, Tuesday, May 19th, 1903.

Southern Hotel, St. Louis, Missouri.
3621 2:00 P. M., Tuesday, May 19, 1903.
Parties met pursuant to adjournment.

Present, the Commissioner and same counsel representing the respective parties.

WILLIAM THOMPSON SEDGWICK,

Resumed the stand for further direct-examination by Attorney General Crow, and testified as follows:

Q. Professor, what knowledge have you of typhoid fever epidemics having been conveyed by water through the water supplies of cities and towns?

A. I have a rather extensive knowledge on that subject, General.

Q. Well, just state generally?

A. Setting aside epidemics derived from wells, which I presume you don't care to go into.

Q. No sir.

A. The most celebrated and important epidemic in this country was certainly,—up to a very recent time,—one which happened at the little mining town of Plymouth, Pennsylvania, in 1885. On the watershed of that town they had built four storage reservoirs and on the bank of the stream which supplied the uppermost of those reservoirs, a case of typhoid fever appeared in the early spring of 1885. The reservoirs had all 3622 been drawn very low owing to a cold spell which they had had, and on the arrival of the spring thaw, 1200 cases of typhoid fever broke out in this little town of 8,000 inhabitants. These were traced,—and it is believed by sanitarians, were correctly traced,—to the occurrence of one case of typhoid fever on the bank of the uppermost reservoir, followed by the washing during the thaw, of the dejecta of that patient, and in the lo state of the reservoirs, its rapid transmission to the people of th town. It was a dramatic and terrible event. I will make th just as short as I can because if I did not, I should take all th afternoon. That was in 1885. In 1890, came the Lowell epidemi of which I have spoken, investigated by myself. That was fo lowed close after—I will say instead, very soon after, by worse one in Lawrence, nine miles below. This was traced t the infection which I referred to, which began upon Stony Brook and of course the Lawrence case was caused largely by the typhoid fever germs in the sewage of Lowell, the larger city abo it,—nine miles distant—

Q. What was the extent of the epidemics in the two towns

A. In Lowell I investigated personally, or had investigated some 550 cases, but from the number of deaths and fro the cases we knew, and so on, we estimated there were a thousand of them.

3623 MR. TODD: That was in Lowell alone?

A. That was in Lowell alone. In Lawrence, just belo there were several hundred cases,—and a larger incidence in proportion to the population.

Two years after, in 1892, I investigated a very interestin epidemic on the same river, in the city of Newburyport, which i at the mouth of the Merrimac river. The Newburyport epidemi was a small one, for Newburyport was a small city. The Newburyport people supposed that they were drinking a spring water, but surreptitiously the superintendent of the waterworks ha connected the mains with the Merrimac, and the people wer really getting, as he himself admitted, for some two or thre months, Merrimac river water, and this was particularly instructive because for the first two months, we will say, of the tim that they got that Merrimac water, there was no typhoid in Newburyport. On going up the river I found that the reason for th was that they had been drinking simple filth,—good straigh sewage, uninfected apparently; but unluckily for them a littl epidemic broke out in Lowell after they had been drinking fro the river for a while there in Newburyport, and some sevent

cases appeared there (in Lowell),—a larger number than they had had since the big epidemic. We found that the result of those cases in Lowell was perfectly obvious in Lawrence, although the water had had to travel nine miles and pass
3624 through a storage reservoir where it had been detained for at least a week, and that it was proportionately almost as much marked, perhaps just as much, in the number of the details. Now in Newburyport, the distance from Newburyport being, as I remember it, about,—I think it is 25 miles; I have forgotten just how that is—

MR. FULLER: Newburyport to Lowell; I think it is more than that.

THE WITNESS: I have forgotten what the distance is.

GENERAL CROW: Approximately, anyway?

A. It is 20 or 30 miles; I have forgotten just how far. When they got this water which had been infected,—when they not only drank sewage but infected sewage—when they not only drank filth but drank the germs of disease, this epidemic occurred in Newburyport, and it was one of the saddest cases I ever investigated, because the people supposed that they were drinking spring water, and they were drinking this infected sewage. That was in 1892. But it was small. In Newburyport there were eight deaths; but it was a very instructive epidemic as showing how things may be carried in running water.

The Rivers Pollution Commissioners of Great Britain, in a report published by them in 1874, state that there is no river in the United Kingdom long enough to purify itself from any
3625 sewage admitted to it, even at its source. That stands as one of the axioms of sanitary science today; those Rivers Pollution Commissioners in 1874, I think it was, made that statement, that there is no river in the United Kingdom,—I think they said,—long enough to purify itself of any sewage introduced into it—introduced at its source, and of course some of the rivers of the United Kingdom are very long.

Now that (the Newburyport epidemic) was in 1892-3. About that same time I was sent by the State Board of Health of Massachusetts to watch the epidemic in Windsor, Vermont. Windsor, as you may know is a pretty summer resort to which William

M. Evarts and other lawyers,—have resorted for years. Their water supply was derived from a dammed up brook, but they had an epidemic of typhoid fever there which was attributed by the State Board of Vermont, to one case of typhoid fever on the watershed above—not very far above, a mile perhaps, and that case was a very severe and dramatic one; the town was in mourning, and the affair was a very sad one. I did not make a lengthy investigation of that, but it is one of the well known cases.

As I have already said; in 1898, I think it was, I made a special study of typhoid fever in Pittsburgh. Acting on advice of one of the most eminent engineers of the time, Pittsburgh intro-
duced a water supply a number of years ago,—twenty or
3626 thirty years ago, drawn from the Allegheny river, mainly,
and partly from the Monongahela. Now the Allegheny is a swift stream with only remote pollutions. There is no near pollution that amounts to much, if anything,—but the remote pollutions from Oil City, etc., and as a result of the careful study of that epidemic prolonged for some weeks—not of that epidemic but of the study of cases of typhoid fever in Pittsburgh, it resulted in the recommending of the filtration plant for the city of Pittsburgh, for the reason that in my judgment infectious materials might be brought to cities which had no filtration plant, from points as distant as Oil City, or even more remote,—113 miles or more. I reported that in 1898, and am on record as having said that in 1898.

Q. What was the character of that epidemic there at the time?

A. It was a serious one, something like the Chicago conditions, where they had a large amount all the time,—and an excessive amount frequently.

Q. Was it traced to the water supply?

A. It was by me, and by the citizens. It was generally attributed to the water supply. They got me out there to see if they were probably right about it; as far as I know they generally accepted my conclusions.

Another very serious epidemic due to pollution on the water-
shed, of the public water supply, was that at New Haven,
3627 Connecticut, about three years ago. The city of New
Haven, Connecticut, gets a part of its water supply from

a certain inhabited water-shed—not very thickly inhabited,—but under conditions similar to those in Pittsburgh, Pennsylvania. They had drawn their reservoirs down low owing to a freeze-up, and in the spring, in March, the thaw came and then followed a big rain—tremendous, with the result that, as it turned out afterwards, some feces were washed from a house on the watershed where there had been a very few cases of typhoid fever—if I remember right, there were two or three only,—washed down into one or the other large storage reservoir, which, however, as I have said was very low. The result, was that the water was shot through that pretty fast, and this stuff came quietly to the citizens, and they had 470 cases of typhoid fever in the spring—not in the fall, when typhoid fever cases in communities generally occur. Now I am familiar with the conditions there because as I said this morning, I am a Yale man, and it so happened that at this time there was a big rain. I was in Hartford, which is only thirty-six miles away, and found the water in the taps there muddy from the sudden washing that had come down the watershed. It was the same rain of course—

Q. Were those cases on the watershed traced as the origin of this epidemic?

A. Yes, these cases on the watershed were traced by Dr. 3628 Smith, dean of the Yale Medical School, who proved, as far as we can prove anything of this kind, that this was the probable cause of the epidemic, and it was generally received as such by the experts and by the public.

Then another epidemic that you have heard of—that everyone has heard of almost, is the recent epidemic in Ithaca, New York, where we have every reason to believe that the conditions were quite similar to those at Plymouth, Pennsylvania, and New Haven, Connecticut. I visited Ithaca a week ago. I was giving a lecture in Buffalo on the protection of municipal water supplies by filtration, and took pains to visit Ithaca and confer with Dr. Soper, the expert who is making the investigation there. I also talked with the Cornell professor of Engineering, and with Professor Williams who is expected to testify in this case, and I think, pretty thoroughly informed myself on that subject. I won't go into details, but it is a matter of feces on a water-shed, and a heavy rain and a slight freshet—slight or heavy, I don't remember which, and the quick carriage of pollution to the citizens below.

Q. How far up the watershed was it?

A. I am not sure about that.

Q. What was the extent of the epidemic?

A. It was a very serious epidemic. Ithaca had a thou-
3629 sand cases, as reported by my friend, Professor Jordan of
Chicago,—and with a considerable death rate.

Those are a few of the epidemics. I might speak of Hamburg, Germany, in 1892, when the water supply of Hamburg got polluted with the germ of Asiatic cholera, and of the fact that the citizens of London are only protected against pollution and infection on the watershed by their filters, as shown by the fact that when one of their filters droke down in 1866 they had a big epidemic of Asiatic cholera.

I might speak of the breaking down of the Berlin (Germany) filters which caused a small epidemic of typhoid fever; of the Altona filters which caused a small epidemic of cholera;—but it is a matter universally admitted among sanitarians that running water, uncared for and unprotected by special processes of filtration or prolonged and very thorough storage, is liable, if from an infected watershed, to convey the germs of disease.

I will spare you any further illustrations.

Q. I will ask you professor, what you know if anything, concerning water-borne epidemics of typhoid fever on the Great Lakes, and especially at Niagara Falls?

A. I have given some attention, as I said this morning, to typhoid fever in Chicago and I have also to the condition of af-
fairs at Detroit, Cleveland, Buffalo and Niagara Falls, and
3630 I found in Buffalo, rather to my surprise, a prevailing feel-
ing among medical men that the time was at hand when Buffalo had got to purify her water because of the pollutions put into the lake at Cleveland and higher points. I found that at Niagara Falls they were suffering severly from typhoid fever which the physicians there, who were present at my lecture, freely expressed themselves as believing to be derived from the sewage of Buffalo which had run down the Niagara river,—Buf-

falo and higher points. I think it is a great question whether the big lakes,—or rather the people who are using the big lakes have not got to give up the use of them after a while. A while ago Professor Jordan reported practically to that effect for Chicago, and Detroit certainly stands in great danger from pollutions at Port Huron and possibly other points, and Cleveland, I have been told—though I am not sure of this, is seriously thinking of giving up its tunnels and going into filtration, because the water that comes down from above is polluted, and the whole question of the extent of pollution of water supplies and the life of the typhoid germ—typhoid and other disease germs in water, is today a very seriously debated question; and as I said this morning the growth of opinion is more and more towards the idea that it won't do to trust to self-purification, provided you have got upon your watershed a heavy or extensive pollution.
